The position of the patient is characteristic and shows the involvement of the muscles which keep the spine erect. He stands with his feet widely separated, the upper part of his trunk thrown far backward, his abdomen protruding, so that a line let fall perpendicularly from the upper dorsal spines clears the sacrum which lies in front. (Fig. 1.)

Fig. 1.

On examining the crease or furrow in the back of the neck more closely, on firm pressure over the side of the fifth cervical vertebra while the head is partly drawn back, the vertebra presents a movable point corresponding to the junction of the left pedicle and lamina: a smooth crepitus can be distinctly felt. There can hence be no doubt that a fracture of the lamina of this vertebra is present. The origin of this may be referred to the accident the boy met in his tenth year while turning a handspring. It is curious, however, that no callus can be detected and that Nature has not established a reparative process. It is hardly conceivable to my mind that motion of the head has failed to permit union. That there may be a ligamentous union is possible. It is also possible that the same cause which produced the loss of substance in the spinous process may have prevented the formation of callus and bony union. However, there can be no doubt as to the motion in the part of the vertebra mentioned, for as soon as pressure is made the patient immediately complains of a sensation as if a "cold, damp wind passed over his side." This sensation is referred in greatest intensity to the right side, and is severe or slight according to the manner in which the pressure is made on the left side of the affected vertebra. The middle line of the body dorsad limits the sensation, which is distributed over the back to the vertebral column, the shoulder, the dorsum of the arm, of the forearm, and over a finger and a half on the ulnar side of the hand; the buttocks, back of the thigh, outer part of the leg, and the entire foot. He says there is a distinct boundary between the affected part (and pointed out this limit in his description) and the part free from this paræsthesia. In the arm and forearm this boundary is well marked and corresponds to the line *a* in Fig. 5. The limit of the sensation on the trunk ventrally is not sharp, and extends but a slight distance ventrad of the axillary line. In the leg and thigh the limit is as distinct as in the upper extremity. The same paræsthesia, but to a limited degree, can be elicited on the left side when pressure is made on the opposite side of the fractured vertebra, but the limit of definition and distribution is not abrupt, and, to use the words of the patient, the paræsthesia "runs into the normal sensation, so as to leave no line by which I can say the cold stops here and the natural feeling begins. Or, in other words, the cold feeling on the right side is of equal intensity from the spine out to the limit at the point of the shoulder, down the side, taking in the back of the thigh and nearly all of the calf of the leg and the foot. On the left side the cold sensation seemed to fade and become less marked at the point of the shoulder, the arm, leg, and foot showing a decrease in the cold feeling." Let it be borne in mind, therefore, that this paræsthesia may be elicited on either side by pressure on the respective opposite side of the vertebra, but that its greatest intensity is on the right side of the body, as is its most abrupt limitation.

Fig. 2.

Muscular Movements.—Owing to the atrophy of the pectoral groups, adduction of both arms is greatly interfered with. He is unable to put his hand to the opposite shoulder. By allowing the arm to hang to his side and by giving it a swing, he succeeds in accomplishing this act. The deltoids being involved, he can not raise his arm to a level with his shoulder, nor can he get his hand to the back of his neck to button his collar, as

was previously remarked. Opposition to extension of the forearm on to the arm is very weak, showing the triceps to be involved in the atrophy. Flexion of the arm on the forearm is likewise affected, the brachial group being the seat also of similar changes.

The muscles of the forearms and hands show a relative and real overdevelopment, the circumference of the lower part of the forearm being greater than that of any part of the lower two thirds of the arm. The thenar and hypothenar eminences are very prominent. Although the forearm and hand appear to be overdeveloped, the grasp of each hand is very weak.

The changes in the trunk and abdominal muscles have been already mentioned, as have those of the thighs and legs.

The feet are likewise involved in the pseudo-hypertrophy; the sole is greatly arched, and the first phalanges, especially of the great toes, are quite strongly flexed on to the dorsum, while the distal phalanges are bent toward the plantar surface, owing to the paretic condition of the interossei. This appearance of the toes has been named by Duchenne "*griffe des orteils.*" (Fig. 3.) The patient can not raise himself on his toes, nor can he flex his feet.

Fig. 3.

He can not cross one leg over the other, neither can he lift his legs from the ground while his thighs are extended.

When he makes attempts to sit down, unless he uses the support of his arms, he falls quickly and spasmodically into the chair. This motion is just like the closing of the blade of a knife, which returns to the division in its case as soon as the opposed force exerted by the spring is released. In rising from a seat he lifts his body by means of his right arm, places his left hand above his left knee, and completes the act by throwing his body forward, using his left hand and leg as the lifting force.

Reflexes.—There is an absolute loss of the patellar reflex on both sides. Ankle clonus is exaggerated on both sides—more so, however, on the right than on the left. Triceps reflex is also increased on both sides, but more on the right than on the

Fig. 4.

left. It is remarkable that with the considerable atrophy of the triceps there should be any reflex at all, much less an increased one. The forearm is quickly extended and rotated outward when the triceps tendon is struck, and shows the preponderance of the conjoined action of the supinators.

Cremasteric reflex is greatly exaggerated, the slightest touch to the skin on the inner surface of the upper thigh being accompanied by a violent retraction of the corresponding testicle. This exaggeration is equally marked on either side.

Sensations.—Tactile and general sensations are normal. Touch, pain, temperature, and muscular and space senses were all examined and were found to show no deviation from the normal. Smell, taste, and hearing are likewise unaffected. Vision is hypermetropic. He met with an accident some years ago to his right eye which resulted in a probable dislocation of the lens of that organ, the iris being retracted strongly to the right. Light and accommodation reactions are perfect.

The functions of the rectum and bladder are unimpaired.

He has normal sexual desires, and has noticed no change in his sexual functions.

There are no paræsthesiæ, with the exception of the one described, which is produced whenever pressure is made on the fractured vertebra.

No Romberg symptom.

Electrical Examination of Muscles and Nerves.—All the muscles and nerves examined, with the exception of a few which will be soon mentioned, showed similar reactions to the respective currents. These reactions differed only in degree, greater or less contraction being dependent upon the amount

of healthy muscular fibers remaining in the individual muscles. Both muscle and nerve showed diminished faradaic excitability, no muscle contracting under a current whose strength meas-

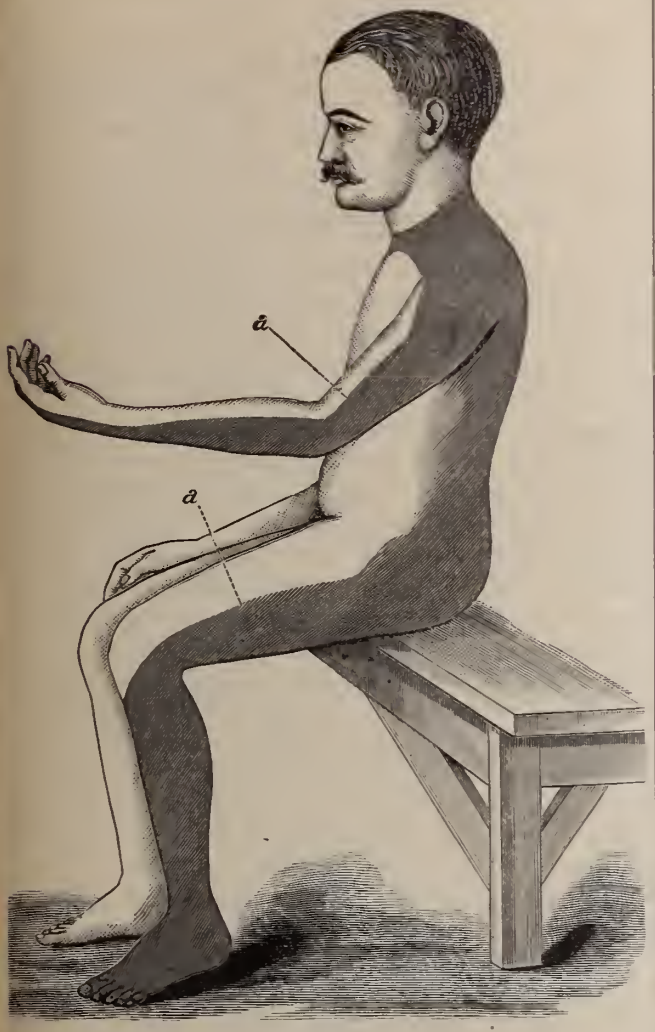

Fig. 5.*

ured less than half the distance of the secondary coil of a Du Bois-Reymond machine.†

To the galvanic current both muscles and nerves responded peculiarly, and showed both quantitative and qualitative changes. Anodal closure and anodal opening contractions were both stronger than cathodal closure, anodal closure stronger than anodal opening. The peculiarity, however, of all the contractions produced, whether the electrode was applied to muscle or nerve, was this: In the first place, it required the strongest currents to produce any contraction whatever, no muscle contracting under a current less than twelve milliampères, applied either to nerve or muscle; in the second place, the muscle was slow in responding, the contraction being tetanic and increasing in its tetanus after the electrode was removed, and *remaining in increasing tetanus for at least two minutes*, as timed by the watch after that removal. At the end of this time the muscle gradually and slowly returned to its previous condition. Only in the left sterno-cleido-mastoid, in the upper half of both the trapezii, and in the abdominal muscles was a normal contraction obtained. Whether the electrode was applied to either muscle or nerve made no difference in the character of the contraction, which, with the few exceptions in the muscles mentioned, was always a tetanus, but more marked when the electrode was applied to the muscle than to the nerve.

The facial muscles and nerves were also involved in this reaction, and in them the peculiarity of contraction was first noticed. The other muscles examined were the pectorals, brachials, triceps, supinator longus, pronator radii teres, the flexors of the hand, the common flexors of the fingers, the individual flexors, the extensors of the hands and fingers, the thumb muscles and interossei, the serratus magnus, the rhomboidii, the levator anguli scapuli, the trapezius, and the erector spinæ. In the lower extremity the gluteals, the adductors of the thigh, the great quadriceps, the sartorius, the flexors of the leg, the gastrocnemii, the tibialis anticus, and the peroneal group. The apparently overdeveloped muscular groups in the forearm and leg showed no difference in their contractions, and required strong currents to bring them forth. The nerves of all the muscles mentioned, where they were accessible, were also examined, either in the nervous trunk or in the branches thereof.

Ætiology.—This is, then, the history of a typical case of pseudo-hypertrophic paralysis complicated by a fracture of a cervical vertebra. There can be no doubt that the trouble in the cord began at the early age of eight months, for at that period the child gave up its attempts at walking, and did not renew them for fourteen months thereafter. Even after it could walk its peculiar gait gave it the name of a "toddler," and its many falls can only be explained on the ground of an affection involving the neuro-muscular system.

It becomes an interesting question to determine whether the accident in weighing acted as a causative factor in the production of this disease. It is very probable that the stretching which the upper part of the cord suffered in the weighing process was so extensive as to interfere with its molecular integrity. All authors agree upon the hereditary neuropathic factor in the production of pseudo-muscular hypertrophy, and none has indicated any other constantly defined ætiological factor. The absence of a neuropathic history in this case, and the fact that attempts at walking had been given up shortly after the cord suffered an injury, would lead one to infer that the injury which the cord sustained in the weighing of the child was an active agent in the production of the disease, if it were not solely responsible. However, I do not insist on this view, but simply mention it as a possibility.

Explanation of Symptoms and Signs.—The inconsistency of the various reflexes merits but a moment's discussion. The total absence of the patellar phenomenon can only be due to the great atrophy of the quadriceps extensor. And yet when we regard the fact that, although the atrophy in the triceps was almost as extreme as in the great extensor of the leg, the tendon reflex was exaggerated, we are led to think that some other factor is operative in the abolition of that of the latter. The generally increased reflexes—cre-

* The shaded region should have been on the right side of the body, and not on the left as in the figure, the fault being due to a transposition of the drawing.

† This coil is made of a wire whose length is 600 m. and whose diameter is 0·225 mm. The scale of this faradaic battery ranges from 0 to 100; the secondary current produced no contraction at a distance less than 50 in any muscle examined, with the exception of the left sterno-cleido-mastoid, the upper half of the trapezius, and both abdominal obliques. These contracted with the coil at 10, 13, and 16, respectively, a normal irritability.

masteric, ankle clonus, triceps—are certainly consistent with the spastic gait, all of which are probably due to pressure on the cord by the fractured vertebra. However, it has been shown, and it has been my own experience, that when the lower portion of the quadriceps extensor is the seat of pronounced atrophy, especially the portion adjoining the tendon, it is impossible to elicit the reflex.

The athetotic contractions in the right upper extremity are a little more difficult to explain. They appear to me to be due to the loss of contractile equilibrium between the extensor and flexor group, and are elicited by the unequal contractions of the various muscles employed in the act which called them forth, co-ordinated action between antagonists being lost by reason of the unequal atrophic process. The pressure of the fractured vertebra may also be an element in the production of this symptom, as it certainly is in the production of the spastic gait.

The electrical reaction is anomalous, notwithstanding the fact that it adheres to the law of degenerative reaction. In the entire literature that has been accessible to me I can find no mention of the fact as it exists in this case; that *ordinary* contractions can not be elicited by any strength of galvanic current, the very first indication of contraction being immediately a *tetanus*, equally produced whether nerve or muscle be galvanized, but produced by feebler currents in the former than in the latter.

The symptom of most importance to us is the sensation of cold, having a definite distribution and following every pressure made upon the posterior segment of the cord.

The course and location of the temperature-sense tract are unknown. Goldscheider has made experiments to test them, and has analyzed the intrinsic relations of the temperature sense to the other cutaneous senses. The general idea seems to be that the temperature-sense tract runs together with the tracts transmitting the other cutaneous sensations. It is a well-known fact that in systemic diseases of the spinal cord, such as tabes dorsalis, the involvement of tactile perceptions follows the distribution of the ulnar and sciatic. In this case the subjective sensation of cold follows the same distribution, from which we are led to infer that the temperature-sense tract is situated in the posterior segment of the cord, and near, intermingled or identical with, the tract for tactile impressions. While this conclusion is presented as a mere supposition, this peculiar *intra-vitam* experiment proves one fact beyond doubt—viz., that, be the temperature-sense tract identical with, or regionally related to, or even remote from other tactile transmission channels, it follows the same laws in regard to peripheral distribution for the same areas which are exquisitely involved in spinal-system diseases causing anæsthesias and paræsthesias. In other words, this case would sustain the proposition that there was a homology in the distribution of peripheral sensation tracts in the cord whose general laws can not be formulated to cover all physiological contingencies. The pain-sense tract has already been proved to harmonize with this general law; that, as in cutaneous space-sense disturbances, a systemic disease must involve the posterior segment of the cord in an area which is too familiar to you for me to define; and from this case it is evident that the temperature-sense tract follows the same law as regards distribution, the sciatic for the lower and the ulnar for the upper extremity being the weaker points.

SOME CONSIDERATIONS ON THE NATURE AND TREATMENT OF EXOPHTHALMIC GOÎTRE.*

By J. LEONARD CORNING, M. A., M. D.,
NEW YORK,
CONSULTANT IN NERVOUS DISEASES TO ST. FRANCIS'S HOSPITAL, JERSEY CITY; THE HACKENSACK HOSPITAL, ETC.

The salient features of Graves's disease—enlargement of the thyreoid gland, protrusion of the eyeball, and acceleration of the pulse—are doubtless familiar to most physicians in active practice. I sincerely wish that our knowledge of the pathology of the affection were equally accurate. Unfortunately, post-mortem research has not done much to enlighten us on this point, so that what little has been found is in no respect decisive, either as regards the location or character of the lesion. Inasmuch, therefore, as all efforts to solve the question by direct observation in the dead-house have heretofore proved futile, we have been forced to lay hold of the less exact resources of deduction. By comparing the three fundamental symptoms of the disease with what has already been ascertained, or partially ascertained, regarding the physiology of the central nervous system, we have been enabled to construct a theory of the disease which, whether it be objectively true or not, affords, at all events, a hypothesis which may be carried to the bedside without danger to the patient. The theory to which I refer is that which ascribes the symptoms of the disease to a functional disturbance of the sympathetic system, and it is this theory which I believe we must accept until something more plausible is forthcoming.

As physiological experiment has clearly shown, the functions of the sympathetic are manifold; certainly vasomotor, cardiac, oculo-pupillary, trophic, and secretory fibers have been pretty clearly made out. While this system of nerves throughout its entire course is interesting, it is the cervical portion which most concerns us here. Several most interesting observations have been made on this part of the nerve-plexus. In the first place, Claude Bernard has shown that division of the cervical sympathetic in animals is followed by dilatation of the vessels of the neck and head on the same side. Conversely, it has been shown that electrization of the peripheral end of the divided sympathetic causes contraction of the dilated vessels of the neck and head, with concomitant lowering of the temperature on the same side and bulging of the eyeball.

Another noteworthy observation in connection with the sympathetic is the fact that the heart's action is accelerated by irritation and retarded by division of the nerve.

Now, the purely clinical and practical objects of this paper do not admit of further digression in favor of physiological theory; nevertheless, enough has been called to mind, I trust, to show with reasonable clearness that the

* Read by invitation before the Newark Medical and Surgical Society, June 19, 1890.

acceleration of the pulse, and possibly the exophthalmia, may be explained by assuming that the sympathetic is irritated at its cervical part, or at some point above it. But how shall we account for the goitre? for, indeed, some writers affirm that the theory of sympathetic irritation is wholly opposed to the dilated condition of the vessels in the enlarged thyreoid. To my own mind the logical difficulty is more imaginary than real, inasmuch as one may perceive in the enlarged vessels of the thyreoid nothing more nor less than one of the inevitable results of the increased vascular tension. The patient complains of pulsation in the head, and his eyeballs are driven forward by the distended vessels in the orbit. What wonder, then, that compensatory dilatation takes place in the direction of least resistance, and at the point where the blood-current is strongest? Is there any other point which so well fulfills these prerequisites as the thyreoid? Most certainly I know of no such locality. Let us conclude our reasoning, then, with the admission that the theory which looks to irritation of the sympathetic as a prominent, if not the most prominent, cause of exophthalmic goitre is reasonable, and certainly not to be discarded until the evidence in rebuttal has been materially augmented.

Symptoms.—Although exophthalmic goitre is subject to a certain amount of variation in its mode of development, the following account of the disease is applicable in a large proportion of cases:

As a rule, the evolution of the symptoms is gradual, but this is not always the case, for in some instances the affection pursues an exceedingly rapid course, attaining its maximum degree of development in forty-eight hours. Cases of this kind have been aptly characterized as "acute," inasmuch as recovery may take place in a few weeks, or even less. The advent of the disease is often heralded by a variety of nervous phenomena, prominent among which are sudden outbreaks of anger, vague indescribable sensations in the head, and mental irritability. These manifestations may persist for a variable length of time, but, sooner or later, they are followed by one of the prominent symptoms of the disease. In many instances the apprehensions of the patient are first aroused by palpitations and a feeling of fullness in the head. If the pulse be examined at this time, it will be found to average from one hundred and ten to one hundred and forty-five, or more. The condition of the circulation is specially striking in the neck, where the carotids are seen, even at an early period, to pulsate with great vehemence.

Simultaneously with or shortly after the advent of the cardiac symptoms the thyreoid gland begins to swell, and soon the enlargement—which, however, is never very great—is quite perceptible, so that the patient resorts to a high collar or cravat, with a view to hiding the deformity. When the hand is placed upon the tumor a distinct thrill is felt, and, on auscultation, characteristic murmurs, emanating from the distended vessels, may sometimes be heard.

Shortly after the enlargement of the thyreoid the eyes begin to bulge—a condition which gives rise to a peculiar staring expression. Sometimes the exophthalmia is so great that the eyes appear to hang from the head, as if about to drop from their sockets. Such extreme protrusion is, however, exceptional. In most cases the deformity is about equal on both sides; sometimes, however, especially during the earlier stages of the disease, one eye may project more than the other.

Examination with the ophthalmoscope, after the disease has lasted some time, reveals more or less arterial pulsation and tortuosity of the veins. This at least is true in many instances. Again, while accommodation is rarely impaired, there may be slight diplopia when the patient attempts to read or to scrutinize objects in his immediate vicinity. Conjunctivitis is common, owing probably to the inadequate protection afforded by the upper lid, which, in some cases, is not depressed to the physiological limit. In this connection it is worthy of note, as first pointed out by von Graefe, that, when the eyeball is moved up and down, the upper lid does not move in concert with it. To this phenomenon considerable diagnostic weight has been assigned by various authors, who have sought to explain it in different ways. I am inclined to think, however, that too much importance has been ascribed to it, as, in my experience, it is not a very constant symptom.

Testimony is conflicting with regard to the temperature in exophthalmic goitre. In my experience it is normal or nearly so, elevations of 1° or 2° F. being rather exceptional. Excessive perspiration and a subjective sensation of extreme heat are, however, quite common.

The condition of the heart is naturally a question of great importance; in some cases, aside from great vehemence of action, nothing whatever of an abnormal nature is discoverable either before or after death. In others, however, there may be dilatation of the heart, hypertrophy of the left ventricle, or disease of the valves.

Besides the symptoms just mentioned, those who suffer from exophthalmic goitre are often the victims of concomitant nervous disturbances, ranging in severity from tremor, headache, general nervous exhaustion, vertigo, feebleness of memory, and insomnia, to epilepsy, hysteria, and insanity.

A certain precipitancy of speech, abruptness of manner, and unseemly haste are peculiar to almost all cases of Graves's disease.

As previously remarked, the cases which run an acute course are exceptional; as a rule, the disease lasts a long time. Periods of real or apparent improvement may occur, but relapses are prone to take place, though it is a remarkable fact that the disease is sometimes arrested, and recovery attained in the most unaccountable manner.

In the fatal cases the patient loses flesh more or less rapidly and dies of exhaustion, or the heart becomes enlarged and is ultimately unable to perform its functions; or, finally, death occurs as the result of some intercurrent affection.

Diagnosis.—When the three principal symptoms are well developed, little difficulty will be experienced in arriving at a correct opinion as to the real nature of the trouble. As a matter of fact, however, it is quite common to meet with undoubted instances of Graves's disease in which either the goitre, the exophthalmus, or the cardiac disturbance is absent. In irregular cases of this sort we must rely prin-

cipally upon a careful study of the collateral symptoms—the profuse diaphoresis, the headache, the irritability, the tremulousness, and other nervous phenomena—in framing a diagnosis.

Causes.—Prominent among the exciting causes of exophthalmic goitre may be mentioned prolonged worry, sudden fear, anger, and, in short, inordinate emotionality in general. As predisposing factors are a weak neurotic condition of the patient and a special hereditary predisposition. Cases are quite common in which several members of the same family have been affected by the disease in the same or successive generations.

I have myself recently had a case under treatment in which I was able to trace the disease in the direct line for three generations.

Finally, the disease is much more frequent in women than in men.

Morbid Anatomy.—As has already been said, the autopsy has not helped us much in so far as the establishment of an anatomic basis for the disease is concerned. The data available are at once meager and contradictory, so that anything more than a shrewd surmise as to ultimate causation is impossible.

Some observers, like Fournier, Wilks, and Ollivier, have failed to find any noteworthy changes in the cord or ganglia of the sympathetic system, while, on the other hand, Moore, Peter, Trauble, and others have found more or less extensive alterations in these structures. The more noteworthy changes mentioned in literature are atrophy of the ganglia, proliferation of connective tissue, and consequent obliteration of nerve elements and hypertrophy of the ganglia.

It is quite useless, in the present state of knowledge, to attempt to reconcile these two phases of conflicting opinion, and I shall therefore refrain from discussing them further.

Treatment.—In view of the chaotic condition of the pathology of the disease, it is evident that very little inspiration of a practical kind is to be derived from that source. But while this is impossible, while the treatment of the disease can not be based upon its real or imaginary pathology, valuable assistance regarding its management may be derived from purely clinical sources.

Looking at the question from this standpoint, two facts of commanding importance impress themselves upon the physician. First and foremost is the phenomenal disturbance of the circulation, and, secondly, the profound constitutional impairment. No system of treatment is worthy of a moment's consideration which does not take cognizance of these.

With a view to neutralizing the morbid distribution of the circulation and improving the nutrition of the patient, I have had resource to a plan of treatment which may briefly be described as follows:

In order to prevent the excessive blood-pressure in the thyreoid, cranial cavity, and orbit, I have placed the patient in a warm bath, at least once a day, and caused her to remain there for three quarters of an hour or more. When the derivative action of the bath has seemed inadequate, I have applied elastic straps around the legs of the patient, either above or below the knee, according to the amount of derivation which seemed admissible in each case. The constriction of the bandages is never excessive, since they are adjusted in such a way as to interfere more or less with the venous circulation, but not with that in the arteries. While these precautions are observed below, the swollen thyreoid is treated with a special preparation of styptic collodion, whose constricting properties are further enforced by a carefully adjusted elastic truss. I have also bandaged the eyes during the emersion; but I am not certain that this has been efficacious, in so far as a permanent reduction of the exophthalmia is concerned. On the other hand, the application of elastic pressure to the thyreoid certainly does good, and this is more especially the case when such pressure is combined with concomitant expansion of the veins of the lower extremities, as in the method just described. A case of Graves's disease, occurring in a lady of twenty-five and referred to me about three months since, is an illustration in point. At the time of beginning treatment the circumference of her neck at the most prominent portion of the tumor was a little more than fifteen inches. The present measurement at the same spot is a trifle over thirteen inches—an appreciable reduction certainly.

In addition to the foregoing measures, I am in the habit of submitting the tumor to daily applications of galvanism, employing for this purpose an electrode of potter's clay moistened with iodine and of sufficient size to envelop the entire thyreoid. This electrode, which is most serviceable for the purpose, is connected with the positive pole of the battery, while the negative, composed of a large flat sponge, is placed at the back of the neck.

As regards the duration of these applications, I may say that I continue them for from ten to twenty-five minutes twice a day at least. Not much good is to be anticipated short of six weeks or two months. The faradaic current I do not employ, or, to speak more correctly, I do not apply it to the tumor. However, it is doubtless of benefit when used in a general way.

The question has often been asked, and will doubtless continue to be asked in future, What shall we do to regulate the heart's action? In reply I would say that our action in this regard must be largely governed by circumstances. When the pulse is rapid, say from 125 to 145, and the arterial tension notably increased, especially at the carotids, aconitine may be given with great benefit. On the other hand, where there is no notable increase in the pulse, which say at 90 is lacking in fullness, digitalis, sparteine, and strophanthus are clearly indicated.

We next come to a question of great if not paramount importance—the diet of the patient. Nothing is more certain than that neglect to improve the general nutrition of the subject will be followed by disaster. It is incumbent, therefore, upon the practitioner to pay due heed to this point as soon as the character of the disease has been made out. In my experience, a judiciously regulated but not exclusive milk diet is to be preferred. To the milk, which should be taken in quantities ranging from two to four quarts a day, bread and butter, poultry, and game in moderation may be added. A raw egg carefully beaten up with

sugar and milk may be given with advantage two or even three times a day. Some patients, however, refuse to have anything to do with the mixture unless brandy or whisky is added; and since alcohol in all its forms is absolutely contra-indicated in most cases of Graves's disease, it is perhaps better to give the eggs as an omelet or poached.

Should there be the least falling off in the appetite of the patient, bitter tonics may be given without stint.

It is hardly necessary to add that both iron and arsenic may be given with advantage, provided the stomach of the patient will bear them.

Finally, it is necessary to shield the patient from emotional excitement and mental strain of all kinds, and to divert her thoughts from herself. Simple games, musical entertainments, and a moderate amount of reading may be prescribed with confidence, as being the best means of preventing the habit of morbid introspection.

Prolonged cerebral rest I regard, too, as of the utmost importance. By this I do not mean that the patient should be kept in bed for inordinately long periods, but that while there she should remain unconscious. Only in this way is that rest of the higher nervous centers to be obtained which is so surely demanded. In this connection I would remark that in my opinion the subjection of patients who are sufferers from Graves's disease to what is familiarly known as the "Weir Mitchell treatment" is a great cruelty. Patients who suffer in this way are exceedingly irritable and restless, and to demand of them that they shall remain for days or weeks in bed, more or less wakeful for a considerable portion of the time, is not good practice. I have seen patients who have sustained great injury in this way.

The best method of affording necessary rest to the patient without irritating her is to keep her asleep at night, or so long as she maintains the recumbent posture. This may readily be done by the use of a little dexterity, without excessive resort to drugs. At the present time, for example, I have a lady under my care who has suffered from Graves's disease for about a year and a half, and who is able to sleep from ten to fourteen hours out of the twenty-four without sedatives. This she was not able to do when she first came under my care; but, by the utilization of habit and the elimination of psychical and sensory irritation, she is now able to sleep as much or more than she cares to.

53 West Thirty-eighth Street.

THE TREATMENT OF HÆMORRHOIDS.*

By CARTER B. HIGGINS, M. D.,
SURGEON IN CHARGE, WABASH RAILROAD HOSPITAL, PERU, INDIANA.

From the earliest recorded period there has cumbered the earth a class of humanity whose only object in life has been to become possessed of the honest accumulations of thrifty and credulous people without returning any adequate equivalent. Individuals of this class are usually characterized by bright intellects, which they exercise exclusively in devising schemes of trickery and fraud. A few years ago, immediately following the publication of numerous so-called *Systems of Rectal Treatment*, this class almost in a body abandoned their lightning-rod, fruit-tree, grave-yard insurance, and other schemes, which had frequently brought them in contact with officers of the law, and, arming themselves with hypodermic syringes, "took the road" as specialists in the treatment of diseases of the rectum. By some preconcerted arrangement each fellow was given a special field, and, in confirmation of the adage "there is honor among 'professional purloiners,'" it seldom happened that one trespassed on the territory of another. Not long after the ex-pomologist or electrician had established his route there appeared in the public press of the various towns which he honored with his visits elaborate and extended "puffs" proclaiming the many cures he had effected in cases which had previously baffled the skill of the most eminent and expert surgeons. To these advertisements were attached the names of many more or less prominent citizens, most of whom had attained prominence by having been made victims of some patent right or other swindle directed by a colaborer of the specialist previous to changing his vocation. To morally fortify the allegation there were in most instances attached the signatures of the "atrabilious parson" and the divinity student enfeebled by too frequent offerings at the shrine of Onan. The new scheme for a time proved very profitable, and for many months at each recurring visit the schematist would find his rooms crowded with victims. But gradually the field was exhausted; finally his callers were exclusively those of his early patrons who came urging the fulfillment of his guarantee of "No cure, no pay." Suddenly the impostor disappeared; but we shall hear of him again as the originator of some new project "well calculated to deceive." I wish here to disclaim any intention to reflect disparagingly on the clergy as a body, or on reputable people engaged in the occupations assumed by confidence men. The clerical coadjutors of quacks and the rascally hordes that infest the country in the guise of honest tradesmen sustain the same relation to the honorable followers of their respective callings that the advertising specialists do to the profession of medicine.

The conditions could not well have been more favorable to his success than when the peripatetic pile doctor began his rounds. The treatment of hæmorrhoids had been almost entirely neglected by the general practitioner. Each physician had probably in the early days of his professional career applied the treatment recommended by the authorities, but one trial was sufficient to convince him that his ambition to attain fame and wealth would not be gratified in that direction. The tedious separation of the slough, the slow healing of the resulting sore, the tenesmus, strangury, and other forms of suffering experienced by the patient, together with the doctor's recollection of the fact mentioned by all authorities that death was a possible result of the operation, served to convince him that rectal surgery was not an attractive specialty. In succeeding cases it is not strange that he should exhaust the list of ointments and laxatives before advising operative interference. In rural communities, where every one is familiar with his neighbor's affairs, the result of one operation by

* Read before the Miami, Ind., County Medical Society, July 18, 1890.

ligature or clamp and cautery would excite such distrust in the minds of the people that it would be impossible to find one courageous enough to submit to like treatment until time had obliterated all remembrance of the first case.

The treatment of piles popularized by the "itinerant vagabonds" was for a time thought to be of real value, and some surgeons of national repute gave it a place in surgery by their recommendation. The talented author of one of the most valued text-books on rectal diseases, in the first edition of his work, gave the treatment by injection his unqualified approval, and advised its use in preference to all others. In a recent publication, however, he acknowledges that his hopes have not been realized and again recommends the clamp and cautery. The frequent relapses occurring among cases treated by the roving quacks was for a while thought to be owing to the imperfect and clumsy manner in which the treatment was applied; but time has shown that relapse is the rule even in the practice of educated surgeons. This treatment I believe is no longer advocated by any reputable authority. The instrument-makers will from time to time send us circulars offering what they call "rectal sets" at ruinously low prices, but after they have disposed of their dead stock the treatment of hæmorrhoids by hypodermic injections will sink into deserved oblivion in company with its unsavory originators.

The treatment of hæmorrhoids by forcible dilatation of the sphincters was, I think, first publicly advocated by the eminent French surgeon Verneuil about sixteen years ago. At that time he professed to have radically cured many cases of the most aggravated character. Immediately following Verneuil's came other statements emanating from French surgeons of the highest standing, all confirming in the most positive manner the wonderful effects of dilatation of the sphincters in the treatment of piles. That treatment so simple, advocated with such earnestness by surgeons of unquestioned ability and integrity and of world-wide reputation, should attract so little attention is indeed wonderful. Our wonder grows when we call to mind the *fundamental* fiasco of Bergeon, which we can not do, most of us, without feelings of shame and humiliation. Upon the recommendation of a comparatively obscure French doctor the profession of the civilized world provided themselves with apparatus to manufacture and force into the intestines of their tuberculous patients, whose poor emaciated bodies were already tortured to the extreme of endurance, a putrescent gas which their feeble digestive powers had already caused to be present in distressful abundance.

The more recent *testicular* experimentation following Brown-Séquard's suggestion resulted in an epidemic of pyæmia which prevailed in every city, village, and hamlet of Christendom. It must not be forgotten that these absurdities developed subsequent to the publication by Verneuil of his success in the treatment of piles.

Allingham's is about the only text-book on rectal surgery which gives the treatment by dilatation respectful notice. He says it may succeed in selected cases, but must not be thought of as a general treatment. Andrews, not having given the method a trial, says it may be desirable in cases of timid patients who cherish a horror of ligatures and instruments. (I wonder if he comes in contact with any who do not?) Kelsey barely mentions the treatment as not worthy of consideration. Since taking charge of the Wabash Railroad Hospital I have had in my service six house surgeons, graduates from four different medical colleges, all high-grade schools. These young gentlemen received appointment on account of high standing in their classes. Not one of them previous to coming here had ever heard dilatation of the sphincters recommended as a curative method in the treatment of piles. Three or four articles have appeared in as many different medical journals published in the United States advocating the treatment. With these exceptions I have failed to see it commended by either English or American authority. The following quotation from Allingham's *Diseases of the Rectum* may account for the treatment suggested by Verneuil having been so entirely ignored by rectal surgeons:

"I do not think in the whole range of surgery there is any procedure worthy of the name 'operation' which can show greater amount of success or smaller death-rate than the ligature of interual hæmorrhoids."

Dilatation of the sphincters may not, in a surgical sense, be worthy of the name 'operation.' If such is the case, I advise the "family doctor" to appropriate it, for, with the multiplied and multiplying specialties devoted to diseases affecting all organs and tissues between the fields of the alienist and chiropodist, inclusive, there is very limited territory in which he may practice.

My confidence in the superiority of the treatment by dilatation was secured by the same nature of accident which convinced the French surgeons—that is, by observing the complete and permanent disappearance of a number of large internal pile tumors in the case of a gentleman who, in connection with his other trouble, developed an anal fissure, dilatation for the cure of which also cured his hæmorrhoids. Dr. Brenton, of this society, reports similar experience, his patient being a lady who had suffered greatly both from strangulation of the tumors and great loss of blood; her fear of any operation suggested for the cure of the piles was too great to be overcome, but the fortunate intervention of an anal fissure induced her to consent to the procedure of dilatation, with the result of curing both fissure and hæmorrhoids and her speedy restoration to perfect health.

I have used no other method in effecting the radical cure of piles for the past eight years, and during that time have succeeded in curing many cases of the most aggravated character. I will not now state the number of cases nor the percentage of cures, realizing that advocates of new methods too often excite distrust by alleging too much. I know of no condition that would forbid the application of this treatment. I have applied it at almost every stage of pregnancy, in four hours succeeding labor, in patients suffering from cirrhosis of the liver far advanced, in cases complicated with enlarged and indurated prostate gland, those with urethral stricture—in fact, I know no reason, where it is demanded for relief, why it should not be resorted to. In 1888 Verneuil reported the results of his application of the treatment during the fourteen years then just passed. He alleged 98 per cent. of cures. He made no distinction in the cases,

"both external and internal, old and recent, large and small, those associated with relaxed sphincters and those with the opposite condition." My experience with the treatment has been no less satisfactory than that reported by Verneuil. My percentage of cures would be increased by eliminating two cases of applicants for pensions, piles being the alleged cause of disability. The applications were still pending when they reported slight if any improvement.

The dilatation is effected as follows: Hook the thumb of your left hand and the middle finger of your right hand so as to include both sphincters on opposite sides of the anus, and gradually but forcibly separate your hands until all resistance ceases, the object being to paralyze the muscles completely. It is commonly advised to oppose the thumbs, but in a great many cases the resistance will be found so strong that it will be impossible to separate the thumbs a sufficient distance. I have in some cases found the sphincters from long contraction developed to such a degree as to give the impression of pulling on an iron ring. I have never known any bad results follow the procedure. No after-treatment is necessary, except in cases where there is complaint of smarting, which may be relieved promptly by the application of a pledget of cotton saturated with a four-per-cent. solution of cocaine. It is always advisable to perform dilatation under the influence of an anæsthetic, the A. C. E. mixture being the one I always use.

Some halting wit, "the result of a feeble hour," has stigmatized the advocates of dilatation as "bung-stretchers"; should we be so characterized, we may console ourselves with the knowledge that Ephraim McDowell was called a "belly-ripper."

A CASE OF COMPOUND FRACTURE OF THE SKULL.

TREPHINING; FORMATION OF A LARGE CEREBRAL HERNIA; ITS REDUCTION, AND COMPLETE RECOVERY OF THE PATIENT.

By JUAN JOSÉ MARTINEZ, M.D.,
GRANADA, NICARAGUA.

Two principal objects have prompted me to publish this case: (1) The nature of the fracture and the treatment it was subjected to previous to operation; and (2) the formation of an immense cerebral hernia, with its reduction and the complete recovery of the patient:

The case has reference to J. M. A., a boy of seventeen, Nicaraguan, of a fairly healthy constitution and of good previous history and habits. While he was riding on the platform of a railway car his hat flew off, and in the attempt to catch it he lost his equilibrium and fell off the car, coming down on his head. A surgeon was immediately summoned, and found the boy in a complete state of coma, with loud breathing and slow pulse.

On examination of the head, he found a lacerated wound of about three inches, stellate shaped, and about the region of the ascending frontal and of the ascending parietal convolutions, near the median line, but to its left side. He also discovered the fractured bone pressing on the brain, but, either from want of knowledge or from indifference as to the future of the case, the boy being poor, he sutured the ragged edges, thus attempting to hide his ignorance or his ill conscience.

This septical mistake he tried to render aseptic by ordering bichloride-solution applications. This treatment was continued for ten days. The boy began to rally about three hours after the accident, finding himself speechless and with hemiplegia of the right side. I understand that his pupils were equally contracted, and that the tongue was not deflected; had severe pain in the head, and about six hours after the injury had gained his consciousness.

On the tenth day I was called to see the case, and found the head a mass of pus and hair, with an extremely offensive odor; the edges of the wound were very ragged, and the sutures had all torn through. The patient was conscious, with complete aphasia and right hemiplegia; defecated and urinated involuntarily. Temperature, 105° F.; pulse, 115; and respiration, 25. Had daily chills and profuse perspiration. In other words, there were symptoms of pus absorption. On retracting the wound, I found a large piece of bone entirely fractured off from the cranial vault and pressing greatly on the brain. Recommended immediate operation.

On April 15th, at 10 A. M., assisted by Drs. R. and F. Chamoiro, I proceeded to operate.

Anæsthetized the patient with the A. C. E. mixture and used strict cleanliness and antisepsis. Extended the lower angle of the wound down to the bone, trephined in that situation, removing the button entire, and, after biting off with the rongeur all the projecting spicula of bone, was able to remove the fractured piece without injuring the brain in the least.

Having accomplished this, I found at the left and superior angle of the wound, and lying under the skin, another piece of bone fractured off; for its removal, extended that angle of the wound and was able to extract it with tolerable ease. I found the meninges torn and the brain extremely congested, but no soft spots were found. There remained in the skull a hole of about two inches and a half in diameter.

Powdered iodoform freely on the wound and dressed it Operation lasted an hour and a half.

3 P. M.—Projectile vomiting.

5 P. M.—Urinated involuntarily; has not vomited since; no shock.

10 P. M.—Bowels moved involuntarily. ℞ Pot. brom., gr. xxx.

12 P. M.—Slept about an hour.

April 16th, 9 A. M.—Temperature, 100°; pulse, 120; respiration, 28. Dressed. From this time on the temperature, pulse, and respiration continued going down, and kept about the normal.

April 17th.—Wound begins to attain a healthy condition. Brain protrudes slightly through opening. A cerebral hernia that could not be prevented was commencing to form, and it continued growing in size until the tenth day after the operation, when it had attained the size of a man's fist. I consulted all my works on surgery. Some advised me to leave it alone to degenerate, others to cut the protruding mass. I preferred the conservative plan and left the tumor alone, using a fifty-per-cent. alcoholic solution of 1 to 3,000 bichloride. This application was continued for six weeks, as there was a marked diminution of the tumor, preserving all the time a hard and healthy consistency, and the boy was gradually gaining his speech and the use of his limbs.

Up to this time the boy has maintained the horizontal position.

June 28th.—Left his bed. The tumor has been completely reduced and a thick tissue of new formation covers the opening in the skull. The boy has gained flesh during his confinement and is feeling very well.

This result has surprised me, as I did not think the boy would live two days after the operation, such was the injury and the condition of the wound.

As to the reduction of the hernia, I do not know how to explain it. I certainly do not think it took place by degeneration, the brain maintaining such a healthy appearance all the time and the patient having regained all his functions. Whether the alcohol treatment had any influence I do not dare to say, but should be most happy to hear the result of another trial.

REPORT OF A CASE OF ACUTE PURULENT PLEURISY.

*PLEUROTOMY, FOLLOWED BY RAPID RECOVERY.**

By J. D. SULLIVAN, M.D.,
BROOKLYN.

It is only within a comparatively recent period of time that acute purulent pleurisy has been recognized as a primary disease. At the time when many of us were receiving our medical education, we were taught that empyema or pus in the pleural sac always resulted from a degeneration of a serous or fibro-serous fluid, which had been effused into that cavity, and that the change from serum into pus was due to the admission of air either through a fistula into the bronchial tubes or through an opening in the chest wall. But parallel with the general progress of medicine and surgery our views of its pathology have materially changed, and our knowledge of the subject largely increased and better defined.

Of recent years, owing to aids given by exploratory puncture, and especially since the invention and general application of the aspirator, purulent pleurisies have been thoroughly investigated. Although Dieulafoy demonstrated that in all effused liquids in the pleural sac there were present red globules and leucocytes, and others have established the fact that the apparently serous pleural effusions generally contained pus cells, Wilson Fox, in 1877, showed that there was but little natural tendency in serous effusions to undergo purulent transformation. He expressed the opinion that the great majority of suppurative pleurisies were such from the early periods of the disease. From my own experience I am convinced that a large proportion, at least, of the cases termed empyema are primary purulent pleurisies. There is undoubtedly some peculiarity in the character of the inflammation, or in the condition of the patient, which causes the effusion to contain a sufficiently large number of leucocytes to determine its purulent properties.

The following case is of interest as proving the primary character of the disease, and illustrating the beneficial effects of early diagnosis and appropriate treatment:

Freddie W., aged seven years, of good family history, was taken sick while at school on March 10, 1890, with a very severe pain in his right side, followed by a high fever, rapid pulse, and general distress.

A cathartic was administered, and this was followed by quinine and Dover's powder in moderate doses. On the following day his temperature was 103° F., pulse rapid, and respiration considerably embarrassed by the pain in his right side.

Dullness on percussion was the only marked physical sign elicited by examination of his chest. Medicinal treatment had but very little effect in checking the progress of the disease, and he remained in the same condition for about a week, excepting that the dullness on percussion on the right side increased to absolute flatness. It was evident that there was an effusion taking place in the right pleural cavity, which was gradually compressing the lung and producing greater dyspnœa. The distress of the little patient was so great that he was unable to get much rest or take but little food, and he was emaciating quite rapidly. His temperature continued to range from 102° to 104°, and the pulse continued rapid, becoming more feeble. On the ninth day copious perspirations supervened. By the twelfth day the greater portion of the right side of his chest was absolutely flat on percussion, and the lung was evidently compressed toward the apex. The copious perspirations and rapid emaciation led me to suspect the existence of suppuration going on in connection with the pleurisy.

On March 23d I introduced an aspirating needle into the side, and confirmed my suspicions by drawing off a small quantity of pus. As the needle became clogged by the fibrous masses in the liquid, I was obliged to withdraw it.

Deeming it prudent to make another attempt to draw off the fluid and wash out the pleural sac without opening the thorax on the next day, assisted by Dr. F. C. Hickok, I introduced a medium-sized trocar and cannula between the eighth and ninth ribs in the median axillary line, and, having attached the latter to an aspirator, succeeded in drawing off a few ounces of pus, when the cannula became so obstructed by the fibrous masses that I was convinced of the impossibility of evacuating the pleural sac by that method.

With the boy partially under the influence of an anæsthetic, I introduced a scalpel along the course of the cannula, through the thoracic wall, and made a free opening about two inches in length.

The pus was ejected with such force that a portion of it was thrown a distance of at least eight feet. The quantity of pus and cheesy material evacuated was estimated at five pints. As the fluid escaped, severe coughing was induced and the lung expanded well. The pleural sac was now washed out with a warm solution of chloride of sodium, two drachms to the pint.

A large pad of paper-wool was now placed over the opening and a bandage applied. He rested better the following night than he had since his illness. The next day his temperature was nearly normal, and a cheerful and pleasant countenance replaced the picture of distress which he presented during the last week. A rubber drainage-tube was prepared by dividing the inner end longitudinally for half an inch and deflecting each lateral half to a right angle with the tube and stitching them to the side of the tube, like the letter T, as used by Professor T. G. Thomas for other purposes, and was inserted and secured with a large safety-pin. The pleural sac was daily irrigated through this tube, first with a warm biniodide solution (1 to 12,000), and this was followed by the solution of common salt for the purpose of removing the mercurial. Within the next few days there was a remarkable improvement in the little patient's condition. The copious perspirations ceased, his respiration became quite natural, his appetite returned, he slept well, and was cheerful and happy.

At the end of four weeks the drainage-tube was removed, and five weeks from the date of the operation the wound was entirely healed. On July 16, 1890, four months after his illness, I examined him carefully and found but a very slight retraction of the right side and a slight dullness on percussion. His res-

* Read before the Fifth District Branch of the New York State Medical Association, at Kingston, July 22, 1890.

piration was quite normal and his general health very good in every respect.

Up to within a comparatively recent period pleurotomy has been considered a grave operation, not to be resorted to until all simpler means had failed.

It may be that the tendency at the present time is toward the other extreme, not only to open the chest but to resect a portion of a rib. While the latter procedure is often justifiable or may be necessary in some cases, I believe the majority of patients with suppurative pleurisy may be cured by the minor operation, especially if this be done in the early stage of the disease.

A prompt and definite diagnosis by means of the aspirating needle is of the utmost importance in these cases, for the earlier the disease is recognized the more effectual will be the treatment. In my opinion it is perfectly safe and justifiable to introduce into the pleural sac an aseptic needle, properly guarded, for the purpose of diagnosis. If simply serum is found, its withdrawal by aspiration will be beneficial to the patient. On the other hand, if pus is found, the earlier it is evacuated the better, and pleurotomy may be done immediately, using the needle for a guide. I have had occasion to open the pleural cavity a number of times, both for empyema and pulmonary abscess, but have never yet found it necessary to resect a portion of a rib for the purpose of drainage. When possible, I select the eighth intercostal space in the axillary line as the point of puncture.

The operation is very simple and safe, and in my experience has always been attended with good results.

TRAUMATIC DISLOCATION OF THE CRYSTALLINE LENS,

WITH INCREASED TENSION AND SEVERE PAIN; RELIEF OF PAIN AND RESTORATION OF USEFUL VISION FOLLOW EXTRACTION OF THE LENS.

By DAVID WEBSTER, M. D.,

PROFESSOR OF OPHTHALMOLOGY IN THE NEW YORK POLYCLINIC AND IN DARTMOUTH MEDICAL COLLEGE; SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL, ETC.

Cornelius R., aged sixty, laborer, native of Ireland, came to the Manhattan Eye and Ear Hospital on Wednesday morning, April 23, 1890. He said that he had been pounding stone, and that a piece of rock broken off by his hammer had struck his right eye. He immediately found that he could not see with that eye, and lost no time in coming to the hospital. Dr. W. J. Killen, the house surgeon, examined his eye and found that the anterior chamber was filled with blood, but that no other lesion was visible. The eye retained good perception of light. The projection was good except that in the upper portion of the field it was slow. The other eye had vision $\frac{18}{200}$, raised to $\frac{20}{50}$ with a + 1 D. spherical. The patient was taken into the hospital, atropine dropped into the eye, and a bandage applied.

April 28th.—R. V. $= \frac{20}{200}$, L. V. $= \frac{20}{50}$; no improvement with glasses. The blood has been nearly all absorbed from the anterior chamber, and with the ophthalmoscope the lens can be seen to be dislocated downward, forward, and outward.

29th.—The patient had much pain yesterday and last night. The anterior chamber is very shallow, the iris being pressed forward by the transparent, dislocated lens.

30th.—The anterior chamber is almost *nil;* the pupil is small; the lens has become slightly opaque and is pressing the iris forward. There is severe pain and slight photophobia. Tension +2. R. V. $= \frac{20}{200}$, L. V. $= \frac{20}{20}$.

Under these circumstances it was evident that the dislocated lens must be got rid of or the eye would be lost. As the eye was very red and inflamed, and as ample clinical experience has demonstrated the fact that cocaine has very little if any anæsthetic effect upon inflamed tissues, the patient was placed under ether. A small upward section was made with a narrow Graefe's knife and enlarged with delicate, blunt-pointed scissors. Pressure was made with the spoon as in cataract extraction, but, in spite of the best-directed efforts of the operator, vitreous escaped and the lens began to glide slowly away. The operator, seeing that the lens was about to escape into the bottom of the eye, quickly introduced the wire spoon, and succeeded, after a second attempt, in delivering the semi-transparent lens in its capsule. Some vitreous escaped with the lens and the cornea collapsed. By delicate manipulation the edges of the wound were coaptated, a drop of a solution of eserine (gr. j to ℥j) was instilled, and both eyes were bandaged.

May 5th.—A small mass of vitreous, hanging from the corneal wound and with every motion of the upper eyelid producing irritation, was cautiously snipped off with scissors. The iris above is folded backward upon the ciliary body, making it look as though there had been an iridectomy upward.

6th.—The eye has been quiet since the protruding vitreous was snipped off. A shade has been substituted for the bandage, and the patient allowed to go home and come to the clinic as an out-patient.

8th.—The eye is clearing up and becoming white again very rapidly. Counts fingers easily.

16th.—R. V. $= \frac{20}{100}$ with $+\frac{1}{3\frac{1}{2}}$. There has been no pain since the extraction of the lens. Ophthalmoscopic examination shows floating bodies in the vitreous.

June 20th.—V. $= \frac{20}{50}$ with $+\frac{1}{4}$.

There are some points worth noticing in this case. First, it may be asked why I did not use the bident devised by Dr. Agnew and so make sure of the lens. My reply is that my experience with that instrument in cases where the lens is still transparent has not been satisfactory. In my hands it has interfered with getting the lens out *in its capsule.* In such cases, the capsule being opened and the lens broken, a good deal of soft lens matter is unavoidably left behind. In short, you can not tell when it is all out, *because it is transparent.* This transparent lens matter remaining behind soon becomes opaque, swells, and seriously interferes with a smooth recovery. Again, the rapid recovery of the eye after so much traumatism was to me something surprising. The patient had had his lens dislocated and the front of his eye filled with hæmorrhage, had suffered severe inflammatory reaction from the injury, and a week later had had the additional traumatism of an operation with loss of vitreous inflicted upon the eye, and yet at the end of a week from the operation he was discharged, his eye as well as eyes usually are at the end of two or three weeks after an ordinary cataract extraction, and with vision that would have placed it among the successes efter extraction of cataract.

The folding of the iris back against the ciliary body is an accident that I have seen before in cataract extractions where vitreous was lost.

NEW YORK, SATURDAY, SEPTEMBER 13, 1890.

PROTECTIVE INOCULATION AGAINST TUBERCULOSIS.

Probably the most noteworthy discovery reported at the recent session of the International Medical Congress was Professor Koch's announcement of a substance that has the power of preventing the growth of the tubercle bacilli, not only in the test-tube, but in the animal organism as well. Guinea-pigs, that are extraordinarily susceptible to tuberculosis, inoculated with this substance acquire immunity to inoculations of the tubercle bacilli; and in animals affected with general tuberculosis, inoculation with the substance will stop the morbid process without any injury to the organism. The experiments are yet incomplete, and their author very conservatively refrains from drawing any other conclusion than that of the possibility of making the body resistant to the action of pathogenic bacteria.

In this, as in other discoveries that have marked new eras in the progress of science, independent observers have touched the threshold at the same time. Koch's omission to state the character of his substance only allows us to surmise that it is similar in character to that discovered by two French observers, who established the date of their discovery in somewhat the same fashion in vogue among the philosophers of the sixteenth and seventeenth centuries. According to *Le Mercredi médical* of August 27th, Dr. Grancher and Dr. H. Martin deposited a sealed envelope with the Paris Academy of Medicine in November, 1889, containing a description of a method of treatment by which they had arrested for a long time the evolution of experimental tuberculosis in rabbits. The publicity that Professor Koch gave to the results he had obtained in making guinea-pigs refractory to tuberculosis, or in curing incipient tuberculosis, induced Grancher and Martin to publish their researches on the same subject earlier than they had intended. In all their experiments they had used the rabbit, making the inoculations by intravenous injections, obtaining thus a tuberculosis that was fatal in a short time, that made local treatment impracticable, and that gave rise to definite lesions in the liver, spleen, and lungs. As the tuberculosis thus created was always fatal, there was a solid foundation that permitted of an exact appreciation of the positive or negative results of a method that was intended to confer a refractory condition or to cure after infection.

Inoculations were made, at the same time, in protected rabbits and in test rabbits in a vein of the ear, of the same quantity of a virulent culture of the *Bacillus tuberculosis* diluted with a small quantity of sterilized water. In a series inoculated on December 31, 1889, the test rabbit died on the twenty-third day, while the protected rabbits lived from a hundred and twenty-six to two hundred and twenty-nine days after the inoculation. The necropsies were negative; the spleen was small; and the liver was free from bacilli, though in the circumlobular spaces there were some embryonic cells, constituting a trace of a tuberculous process on the way to recovery.

They attempted to find a graduated virulence as well as a loss of that virulence, and, while not mathematical, the results were sufficiently constant to be employed after the same fashion that Pasteur used desiccated spinal cords for treating rabies. The most virulent culture is designated as number one, killing a rabbit in five days or less; the cultures numbered two and three are fatal after a variable time, according to the resistance of the animal. Cultures four, five, and six are less fatal, while cultures seven, eight, nine, and ten decrease in strength and do not affect rabbits.

A rabbit is inoculated in a vein of the ear with half a Pravaz's syringeful of a culture diminished in virulence to number six. In a week culture number three is injected, and this is repeated in nine days; two weeks later culture number two is injected, then, nineteen days later, culture number one. After inoculation with number one the animals usually die, though not so quickly nor with such severe lesions as the test rabbits inoculated at the same time. If the inoculations stop at number two, the rabbits live for months thereafter.

Very justly, these experimenters believe that they have succeeded in giving to rabbits a prolonged resistance against sure and rapid experimental tuberculosis, and also in conferring an immunity against that disease, the duration of which remains to be determined. The probable benefit of these discoveries to humanity is so patent that comment is supererogatory.

THE REPUTED CASE OF CHOLERA IN LONDON.

Some alarm was felt throughout this country when, some days ago, the telegraph announced that a case of Asiatic cholera was reported from London. The last English mail brings the detailed history of the case. According to the *Lancet*, the patient, a sailor of the steamship Duke of Argyll, left his vessel at 5 P. M. on the 10th of August in good health. He went to a boarding-house in Whitechapel and continued well until late in the following day. Shortly before midnight he was seized with vomiting and purging, but did not seek medical attendance. On the following morning he went out, was again attacked with the same symptoms, became very weak, and was taken to the Poplar Hospital, where, on admission, he was found to be suffering from marked collapse, cyanosis, cramps, and violent vomiting. Although the symptoms pointed to Asiatic cholera, there was nothing incompatible with the diagnosis of severe so-called English cholera, or cholera nostras; nevertheless, every possible sanitary precaution was taken. No other cases of a like nature had occurred on the voyage, and none have since appeared. The patient recovered under appropriate treatment.

Another explanation might be given of the group of symptoms observed in this case. Arsenic poisoning presents a clin-

ical picture scarcely to be distingnished from that of cholera, and on reading over the report of the honse-surgeon of the Poplar Hospital we were struck with the resemblance of the main features of the case to those of arsenic poisoning. The cyanosis, the sunken eye, the purging and vomiting, all are present when an overdose of arsenic is taken, and it is just possible, when we take into consideration how freqnently such accidental poisonings occnr, that the food the sailor took after landing may have contained some such toxic agent. At all events, it appears strange that, when every sanitary precaution was taken, no chemical analysis was made of the food or of the excretions. Possibly the next mail may bring us the particulars of such an examination.

MINOR PARAGRAPHS.

THE GUILD OF ST. LUKE.

The *Lancet* proposes that the medical profession shall have an annnal Sunday for the pnblic observance of religions dnty in relation with St. Luke's Day, October 18th. The proposition inclndes church attendance on the Sunday immediately preceding or following that day, with some form of discourse or teaching from the gospel of "the beloved physician" and a collection for some benevolent object especially binding upon medical men. This ceremonial should not be limited, it snggests, to any one church, and it is not best perhaps that it shonld be gronped together with the Guilds of St. Luke, since the term guild is to the minds of some a source of irritation and antagonism. The *Lancet* explains that, if a free and wide orgauization could be made in the name of St. Lnke, many physicians wonld attend upon their own saint's day who can seldom, in the whole year's round, find for themselves a day of rest, and who seldom enter at the church, or meeting-house, or chapel door. There are many who stand ready to make sacrifices in order to gather with their fellow-practitioners and who wonld welcome this proposed Sunday anniversary. Another advantage is hinted at, the fact of bringing about a closer bond of union between medical men and clergymen and ministers, so that they may know and appreciate one another better and work together better at the bedside, as they so often have occasion to do.

THE CENSUS OF 1890.

In addition to having been made ridicnlous by an abortive attempt to collect statistics that were not wanted by means of an inquisition that the people would not tolerate, the censns of 1890 seems likely to pass into history as the first United States censns that has not been generally trusted. The Board of Health of the city of New York has lately bronght to light presnmptive evidence that the population credited to the city by the Census Bureau is smaller than its actual population by at least a hnndred thonsand, and this is only one of many instances in which the accuracy of the Jnne enumeration has been challenged on reasonable grounds. The board's interest in the matter turns on the effect that the censns of the city will have, if accepted, on its apparent death-rate, which has for many years exceeded its real death-rate, for reasons that we have pointed out from time to time. The board expects to prove the jnstice of its contention by an enumeration nndertaken by itself in certain selected districts, and then demand a recount at the hands of the Government. What is to be thought of a census bnreau that seeks to obtain statistics of the morbidity of a particular few days, while at the same time, by the blnndering shown in its legitimate work, it vitiates the vital statistics of the greatest city of the nation?

THE MEMORIAL HOSPITAL AT JOHNSTOWN.

The final report of the Johnstown Flood Relief Commission gives an account of the disposition of the $3,740,000 that was ponred throngh their hands. One paragraph of this document refers to the early, constant, and yet nnended medical relief that had its origin in the great calamity. It is not generally known that the sum of $40,000 has been set apart for the construction and eqnipment of a memorial hospital, and that a committee of the commission is now engaged npon the work. This hospital, when completed, will replace that which was established by the Red Cross Society of Philadelphia and continued by its medical staff until late in the antumn of 1889, when it was transferred to the charge of the local profession. This has been and continues to be a most nsefnl measure of relief. The commission has been moved to the construction of the Memorial Hospital by the evident necessity that during the present generation, at least, there shall be medical aid to many snrvivors of the shock and exposure and injuries of the great flood. The motive was nndonbtedly a sound and wise one, but the snbsidy might have been made larger withont detriment to its efficient operations.

THE LATE DR. MATTHEWS DUNCAN.

A telegraphic dispatch brings the sad news of the death, at the age of sixty-fonr, of this very eminent obstetrician and gynæcologist, which took place at Baden on the 3d inst. Matthews Duncan was born at Aberdeen in 1826, and edncated at the grammar school of that town, and at Marischal College and University, completing his studies at the University of Edinburgh and afterward at Paris. From the outset of his career he took a leading position in the profession. He was associated with the late Sir James Y. Simpson in the investigations leading to the discovery of the anæsthetic properties of chloroform, and contribnted largely to the diffusion of knowledge concerning the drng. In 1860 he, with some others, fonnded the Edinburgh Royal Hospital for Sick Children, which is now one of the largest and best institutions of the kind in the world. In 1853 Dr. Duncan began his career as a teacher of midwifery and the diseases of women and children, in connection with the Snrgeons' Hall Medical School, and made for himself such a repntation that when Sir James Y. Simpson died, in 1870, Duncan was the candidate favored by the profession for the chair of midwifery in the University of Edinburgh, and his claims were supported by 420 former and present pupils. His chief opponent was Dr. Alexander Rnssell Simpson, the nephew of the late professor, who had been a successful obstetric physician in Glasgow, but who had never delivered a systematic course of lectures in midwifery. Duncan was supported by the profession, Simpson by the laity; and, as the townsmen, who, as curators of the University, had a large influence, voted together for Simpson, he was successful in obtaining the nomination to the chair. Few medical elections ever caused so much feeling. Indignation meetings were held in London and largely attended by the alnmni of the university, while the induction of the new professor was made the scene of a serious riot by the indignant students, with whom Dr. Matthews Dnncan was very popular. In 1877 Dr. Dnncan accepted the chair of midwifery in the Medical School of St. Bartholomew's Hospital, and moved to London, where he immediately took an enviable position as a consultant, gaining the love and respect of his pro-

fessional brethren as well as that of a large number of patients. Besides numerous articles contributed to the journals of the day, Matthews Duncan was the author of works *On Perimetritis and Parametritis, Researches in Obstetrics, Fecundity, Fertility, Sterility, and Allied Topics, On the Mortality of Childbed and Maternity Hospitals*, and many others.

THE CATSKILL MOUNTAINS.

Dr. William B. Atkinson, of Philadelphia, has been enjoying an outing in the Catskills, and writes to the *Journal of the American Medical Association* as follows: "I dare to offer to your readers from the lofty Catskills, and at about the highest point in the range, some thoughts on mountain scenery and health combined in place of a didactic or clinical lecture. The rare atmosphere united to the grand scenery gives one a feeling of exhilaration which lifts him above all thoughts of disease or its concomitant medication. Even hygiene may almost be ignored, as health here really runs itself. We are so often treated to the phrase 'the Switzerland of America' that the term seems to mean nothing, but for grandeur of mountain scenery, by which humanity lapses into nothingness, this particular portion of New York surpasses everything on this continent. Few of the hundreds of thousands of people living within a radius of two hundred and fifty or three hundred miles in the teeming cities of New York, Brooklyn, and Philadelphia are aware of their proximity to such wonders of nature, and that within half a day's journey they could gratify their sight with a view eclipsing all that we are taught to regard as accessible only after a long and fatiguing sea voyage or railroad trip."

A PREMIUM ON POPULATION.

At the last session of the Legislature of the Province of Quebec a bill was passed authorizing the Government to offer a reward of one hundred acres of crown lands to the fathers of all families of twelve or more living children. The prolific character of the French Canadian *habitant* of the rural districts is proverbial, and no sooner was the bill passed than applications for the one hundred acres came pouring in with alarming rapidity. Up to date no fewer than 1,250 fathers whose quivers are full have presented their claims, and the Premier has been obliged to establish a special office in connection with the Department of Agriculture with a superintendent whose duty it is to investigate the claims, which must be supported by the *curé*, the mayor, and the doctor of the place. The cause of this high birth-rate among the agricultural classes of Lower Canada lies in the fact that early marriages are the rule; added to this, the people lead a healthy life, morally and physically, and, though ready money is scarce, wholesome food is plentiful. This bill, which has now become law, will tend to keep the members of large families at the work of agriculture, and while it will act as an *encouragement des autres*, will powerfully assist in the population of the unsettled districts.

SO-CALLED DELTOID NEURALGIA.

In the *Centralblatt für Chirurgie* for August 9th, Dr. D. Kulenkampff, of Bremen, remarks that the name deltoid neuralgia is unhappily applied by Golding-Bird, in *Guy's Hospital Reports* for 1889, to a rather commonly observed pain at the point of insertion of the deltoid muscle when the arm is raised, especially above the horizontal attitude. The pain is sometimes such as to give rise to a disability that may be mistaken for paresis. It almost always depends on some injury, which often is not serious, that leads the patient to fix or disuse the arm for a few weeks, during which time the neighboring muscles shrink, while a prominence of the deltoid is caused by an accumulation of blood and lymph beneath it, inducing irritation of the terminal twigs of the circumflex nerve when movements are attempted. Sometimes the trouble seems to be rheumatic. Golding-Bird recommends passive motion with the scapula fixed, massage, and blisters in the treatment. Kulenkampff, who considers blistering uncalled for, has found faradization a very effectual remedy.

A NEW ANTIDOTE TO CHOLERA.

According to the *British Medical Journal*, M. Roux has tried to cultivate the cholera microbe of Koch in an infusion made from the refuse of malted barley left after extraction in the brewing of beer. It is a liquid in which nearly all other microbes grow well, except the one above mentioned. This not only will not thrive in it, but when immersed in it is quickly killed. He has therefore suggested to the *Société des sciences médicales* of Lyons that the infusion might be of use in the treatment and prophylaxis of cholera.

THE STARCH POULTICE.

In *La Médecine moderne*, M. Brocq remarks that the starch poultice is almost always badly made. He then gives the following directions for making it: The starch should be blended thoroughly with precisely the right quantity of tepid water to form a paste. Boiling water is poured on to the paste, and the mixture is left on the fire for about a minute, being stirred briskly so as to make it quite homogeneous. It is then spread on tarlatane that has previously had the stiffening soaked out of it.

OVERCROWDING OF THE PROFESSION IN AUSTRALIA.

The *Australasian Medical Gazette* repeats its warning of three years ago to practitioners in older countries "not to think that Australia is still the Eldorado for medical men it once was." On the contrary, it states, the competition is perhaps even greater there than in Europe and the United States.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending September 9, 1890:

DISEASES.	Week ending Sept. 2.		Week ending Sept. 9.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	42	11	30	10
Scarlet fever	17	1	17	1
Cerebro-spinal meningitis	1	0	1	1
Measles	52	10	78	9
Diphtheria	52	16	43	14
Varicella	9	0	0	0

The American Gynæcological Society will hold its fifteenth annual meeting in Buffalo, N. Y., on Tuesday, Wednesday, and Thursday, the 16th, 17th, and 18th inst., under the presidency of Dr. John P. Reynolds, of Boston. The programme includes a discussion on The Diagnosis, Pathology, and Treatment of Extra-uterine Pregnancy, by Dr. A. W. Johnstone, of Danville, Ky., Dr. M. D. Mann, of Buffalo, Dr. J. M. Baldy, of Philadelphia, and others; Under what Conditions can Electricity be of Positive Service to the Gynæcologist? by Dr. A. F. Currier, of New York; On the Question of Ampèrage in the Treatment of Fibroid Tumors by Electricity, by Dr. W. C. Ford, of Utica, N. Y.; In Memoriam—Dr. William H. Byford, by Dr. E. C. Dudley, of Chicago; Vaginal Fixation of the Stump in Abdominal Hysterectomy, by Dr. H.

T. Byford, of Chicago; the president's address; Injuries of the Uterus during Labor, by Dr. A. J. C. Skene, of Brooklyn; Is the Mortality after Gynæcological Operations affected by Climatic Influences? by Dr. H. C. Coe, of New York; Cephalæmatoma, by Dr. H. A. Kelly, of Baltimore; Drainage after Laparotomy, by Dr. T. A. Ashby, of Baltimore; The Relative Antiseptic Value of the Biniodide and Bichloride of Mercury, by Dr. Charles Jewett, of Brooklyn; A Modification of Tait's Operation for Laceration of the Perinæum through the Sphincter, by Dr. H. T. Hanks, of New York; Measurements of the Uterine Cavity in Childbed, by Dr. W. L. Richardson and Dr. A. D. Sinclair, of Boston; Cancer of the Uterus in the Negress, and Physometra due to Cancer of the Uterus in the Negress, by Dr. H. A. Kelly, of Baltimore; Laparotomy for Intrapelvic Pain of Sixteen Years' Standing, by Dr. T A. Ashby, of Baltimore; a paper (title not announced), by Dr. E. W. Jenks, of Detroit; and an exhibition of new gynæcological instruments, by Dr. Hanks and Dr. Kelly.

Society Meetings for the Coming Week:

MONDAY, *September 15th:* Hartford, Conn., City Medical Association; Chicago Medical Society.

TUESDAY, *September 16th:* American Gynæcological Society (Buffalo, N. Y.—first day); Medical Society of the County of Kings; Ogdensburgh Medical Association; Medical Society of the County of Westchester, N. Y.; Connecticut River Valley Medical Association (Bellows Falls, Vt.); Baltimore Academy of Medicine.

WEDNESDAY, *September 17th:* American Gynæcological Society (second day); Medico-legal Society; Northwestern Medical and Surgical Society of New York (private); Harlem Medical Association of the City of New York; Medical Society of the County of Allegany (quarterly), N. Y.; New Jersey Academy of Medicine (Newark).

THURSDAY, *September 18th:* American Gynæcological Society (third day); Metropolitan Medical Society (private); New Bedford, Mass., Society for Medical Improvement (private).

FRIDAY, *September 19th:* Chicago Gynæcological Society; Baltimore Clinical Society.

SATURDAY, *September 20th:* Clinical Society of the New York Post-graduate Medical School and Hospital.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE.

Meeting of May 15, 1890.

The President, Dr. A. L. LOOMIS, in the Chair.

The Auscultatory Percussor.—Dr. LOUIS L. SEAMAN exhibited and explained a new percussor, designed and arranged by him. Some phonographic reproductions of notes previously elicited in auscultating a chest added interest to the description of an ingenious instrument.

Spinal Surgery; a Report of Eight Cases.—Dr. ROBERT ABBE read a paper with this title. He said that his remarks would not be confined to giving a rose-tinted picture of startling achievements of new surgery, but rather to a serious review of some of the grave cases of spinal troubles requiring surgical interference which had of late come under his care. The patients had all been previously subjected to prolonged medical treatment, and were, when referred to the speaker by the physicians or neurologists, in almost a hopeless condition. The popular idea among physicians had been that the spinal cord was more inaccessible to the surgeon than the brain, because of its irregular bony coverings and the hæmorrhage from the venus plexuses that enveloped it, and that injuries and diseases of it were to be looked upon hopelessly unless Nature kindly assumed to work unexpected recoveries. It was from the doomed cases of paralysis of the lower half of the body, and some other spinal troubles, that an effort was being made to cull out some cases which, heretofore neglected, might yield good results. The eight cases might be divided into four groups: (1) three of paraplegia from fracture; (2) one from early curretting of a vertebra for Pott's disease; (3) two of tumors of the vertebral canal with paraplegia; and (4) two of intradural section of some of the posterior roots of the brachial plexus for neuralgia.

CASE I. *Fracture of the Spine between the Eleventh and Twelfth Dorsal Vertebræ, with Complete Paraplegia, Anæsthesia, and Incontinence.*—Operation was performed eleven months after the accident. R. W. G., aged twenty-seven, merchant. The patient had enjoyed good health until May 19, 1888, when he had fallen from a platform twenty-one feet high, while pushing off a large beam. He fell with the timber on sawdust-covered ground, receiving scalp wounds, but it was impossible to say whether the timber had struck him or not. He was unconscious for three hours, and was completely paralyzed and insensitive below the waist when he recovered. Efforts were made, under ether, to straighten the fracture deformity of the spine by extension and manipulation, but nothing was gained. A bedsore had formed at the site of the spinal deformity, and a water bed was obtained. At first it was filled with cold spring-water. This caused the patient so much suffering that, on being placed upon it, he had fainted and had remained unconscious for hours. Complete incontinence of urine had been present from the first. Diarrhœa was succeeded subsequently by complete inaction of the rectum. Three months after the accident the patient had resorted to a wheel-chair and attended to his business, this being the condition when he was referred to the speaker. On April 12, 1889, the operation was performed. The method pursued being typical, it was given in detail, to prevent repetition in the other cases. The back was shampooed the evening before, and a damp sublimate dressing kept applied until the moment of operation. The patient was laid prone, but with one shoulder raised by a sand-pillow, favoring easier respiration and inclining the back toward the operator. A free incision was now made parallel to the spine and half an inch to one side, cutting the longissimi attachments from one side only, and being carried clean down to the laminæ at the second or third pass of the knife. To approach the fracture between the eleventh and twelfth vertebræ the incision was made from the eighth dorsal to the first lumbar spine. The laminæ were now cleared of muscles, which were drawn outward by retractors, and the ligaments divided above the spines of the eighth and below the eleventh, thus isolating a block of four spines, whose bases were then severed from their arches by stout cutting pliers. This manœuvre at once allowed a retraction of the entire block of connected spines with their muscles still attached on one side, and the entire breadth of the spinal arch was thus exposed without sacrificing the overlying tissues. A pair of slightly curved rongeurs was now applied to the lower edge of one lamina, and with ease the entire breadth was quickly gnawed away. Then the arches of the tenth, eleventh, and twelfth were treated in the same manner, exposing the clean spinal cord to the extent of two and a half inches. The twelfth dorsal vertebra was found to have been displaced backward, the fracture running through the articular facets, the pedicles, and laminæ. The cord was compressed between the arch of the eleventh above and the upper lip of the body of the twelfth below; the intervertebral cartilage had been ruptured. In half a minute after the cord had been released from its flattened state, the bone-pressure area being only half an inch deep, the dura became quite as round as it was above and below this point, and presented a perfectly

normal appearance, except that at the upper portion it pulsated. The speaker emphasized this fact because in many of the cases reported the cord had appeared normal, and therefore the dura had not been opened. The wound was then irrigated and dried, and the dura slit up for two inches. Adhesions of various density were found within, attaching the meninges to the dura, forming a complete circular dam, which shut off the upper from the lower part of the canal. Only an ounce of clear spinal fluid escaped, when the head was depressed below the level of the spine. The veins of the cord were not distended, and the adhesions were broken up with very little force. The cord was normal in thickness above the involved part, then, by a sloping rather than abrupt change, it merged into a flattened band for three quarters of an inch, retaining its breadth, but less than half its thickness, the principal atrophy seeming to be in the posterior columns. Throughout this flattened portion the white fasciculi of the cord could be traced continuously, so that there was no abrupt break in its continuity. Before the operation it had been proposed to the patient that if the cord was found to be destroyed within narrow limits, and apparently sound above and below, it might be excised and the fresh-cut ends sutured. Though told that this had never been done, he had accepted the experiment. It proved to be an impossible operation, however, in this case; the speaker had tried to approximate the sound cord on either side of the damaged part by traction made with tenacula imbedded in the meshes of the membranes at such points as would have been available for sutures. There was but slight latitude of motion vertically. Excision of more than a scant quarter of an inch would have made it impossible to approximate the ends by sutures that would not tear out. The damaged cord in this case being of three times that length, and no further repair being possible, the dura was sutured by fine catgut. The displaced spines were brought into line and sutured by heavy catgut to their neighbors above and below. The fascia investing the muscles then received two or three interrupted catgut sutures, with gaps for drainage, and finally the skin was drawn partly together by a few catgut sutures not tied but left for use at the next dressing. No drainage-tube was applied, but a piece of protective, three inches wide, was laid over the wound, the skin edges being left a quarter of an inch apart so as to allow of drainage from the deep portion. The investing antiseptic dressing was covered by a plaster jacket covering only the back like a turtle-shell, and secured by an enveloping Canton-flannel binder pinned in front. In forty-eight hours the dressing was changed. Drainage had been perfect, the wound had healed except the skin, the sutures of which were now brought forward and tied and a final dressing applied. From the time of the operation he had had no pain in the back or extremities. The wound had healed primarily, leaving only a linear scar. He had remained in the hospital for three weeks; there had been no fever or other disturbances; his condition had been watched since the operation, and there had been no improvement in motion or sensation. After returning home, the patient had written that for six weeks there had seemed to be some improvement, but in a recent letter, quite a year since the operation, he admitted having gained nothing. About six weeks after the operation he had passed through a curious two months' illness of the nature of trance; he had come out of this abruptly, and was in every way mentally himself again. This condition was judged to have been an effect left by reaction after two months of exalted excitement and harboring the "exhilarating sentiment of hope," followed by swift appreciation of the unchanged paralysis, and that it was only one of the curious hysterical manifestations occasionally connected with spinal disturbances.

Case II. *Fracture; Paraplegia below the Eleventh Dorsal Vertebra; Duration, Two Years and a Half.*—G. W. L., aged twenty-seven years. In October of 1886 the patient was thrown from his horse and struck his back across a stick on the ground, injuring the spine at the junction of the dorsal and lumbar vertebræ. Instantaneous and complete paraplegia resulted below the waist, with paralysis of the bladder and rectum. He had lain where he fell, exposed to sleet and snow, for a day and a half before he was discovered. He was carried to a farm-house and restoratives were administered; bottles of hot water were applied to his feet—so hot as to cause blistering, which resulted in gangrene. After three weeks he was removed to his home, when it was found necessary to amputate both legs below the knees. The bladder was catheterized for a week after the accident, but subsequently emptied itself without his control or knowledge. Rectal movements were also involuntary. He also suffered from severe sacral bedsores. The paralyzed limbs often had a sense of burning and pain; bending the knee forcibly caused pain. At the time the legs were amputated no anæsthetic was used, but the sawing of the bones caused intense pain. The general health had recovered sufficiently to allow the patient to drive about in his carriage. Several months before coming under the speaker's care, two years and a half after the accident, the patient had unwisely remained in his buggy about seven hours. His anæsthesia had rendered him unconscious of discomfort from prolonged pressure, and there resulted an area of pressure gangrene under each buttock. These sores had refused to heal. The patient now being confined to his back, and the case so desperate, he was placed under the speaker's charge with the hope that some method of operation might be devised for his improvement. Examination showed absolute paraplegia and anæsthesia below the line crossing the sacrum at its upper border and extending in front across the abdomen two inches below the navel. The bedsores under the buttocks were unhealed, exposing the bone. There was involuntary muscular jumping in both legs. Urine showed granular casts, but no albumin. The patient had strong and natural erections with emissions. It was decided that the cord was absolutely severed at the last dorsal, but that below the second lumbar it must be in a fairly healthy condition. The case seemed hopeless unless it were possible to innervate the lower segment of the cord by renewing its contact with the upper. It was suggested, in case the parts were not too much injured, "to cut off a few of the lower dorsal roots long, and of the lumbar roots short, and suture them together, thus increasing the chance of getting sensation." The operation was performed April 18, 1889, by the same method as detailed in the former case. After exposing the spinous arches of the ninth dorsal to the second lumbar inclusive, it was found that a massive and dense eburnated deposit of bone had formed at the site of the eleventh and twelfth dorsal and first lumbar laminæ. This was with difficulty chiseled and cut away until the severed end of the spinal cord was exposed, and found to be completely cut across and the dura sealed up. Below this for an inch and a half solid bone filled the vertebral canal. The cord here commenced again, and its end was found engaged in the bone so that spicula had grown into it. It could not be lifted up to approach the upper end more than half an inch, and it was evident that repair by suturing was hopeless. He had rallied well from the operation.

Case III. *Fracture of the Eleventh Dorsal Vertebra; Paraplegia.*—J. S., aged twenty-one, coachman. On January 1, 1889, when alighting from the rear platform of a car which was going rapidly, he was struck in the small of the back by the platform, falling on his hands and knees; pain was intense in the back, and paralysis supervened at once. A plaster jacket

had been applied and retained for a month. There was incontinence of urine and fæces. Some sensation in the legs and feet. On examination, a slight depression was seen between the last dorsal and the first lumbar spines. A line of anæsthesia crossed the back at the top of the sacrum. At the sides it ran an inch above the crest of the ilium and crossed the abdomen two inches above the pubes. There was atrophy of all the muscles of the thighs and legs, complete paraplegia and anæsthesia of the skin of the lower extremities, showing persistent vaso-motor impressions. He was operated on in February, 1889, the operation being essentially the same as before recorded. At a point underneath the injured arch a circular dam of lymph was found an eighth of an inch wide between the dura and the cord, entirely shutting off the upper from the lower part of the canal. From above this dam the arachnoid fluid flowed freely. The cord at this point showed evidence of having been completely crushed. Just below the lymph dam a mass of largely distended veins occupied the surface of the cord, showing obstructed venous return. These entirely emptied themselves upward when the pressure was taken off. The cord was entirely liberated from its adhesions, the dura sutured with fine catgut, and the wound closed. For two weeks following the operation there had been hyperæsthesia of all the paralyzed parts, but this had abated. The patient recovered rapidly from the operation, but with no improvement of the paraplegia. All operators in cases of fracture paraplegia of any duration had thus far arrived at about the same conclusion—namely, that the pressure of bone was of secondary importance. Except where the fracture involved only the arch, which was driven in by a blow—inasmuch as the violence, usually a fall and bending of the back, which would produce instant paralysis, had done so by a diastasis of the vertebræ, the cartilage being ruptured and the arches broken, which completely pulpified the spinal medulla—the vertebræ were very apt to immediately resume their usual relations. If, however, the fracture took place below the last dorsal, where the medulla had disappeared and the firm cauda equina commenced, the crushing did not usually destroy the nerves, but long bone pressure would. In such cases an operation to correct it was always desirable. It still remained a problem, perhaps never to be solved, how to connect the lower segment of the cord with the upper when there was a gap of half an inch, and whether this union would restore functional connection with the brain, even though its reflex and independent activity might be ever so good.

The next case reported was given simply to show the ease with which the vertebral bodies, if carious, might be approached from behind.

Case IV. *Pott's Disease, taken early and treated as a Tubercular Caries in any Joint would be.*—E. K., aged twenty, glass-worker. Two years before admission the man had had a pleurisy from which he recovered. Subsequently he was cured of a *fistula in ano*, and when he came into the hospital he had slight phthisical changes in the apex of the left lung and a lumbar abscess prominent over the iliac crest. The latter was opened in September, 1889, and discharged profusely through three sinuses around the crest of the ilium. In February last the speaker had found that a long probe could be passed upward to the last dorsal vertebra, and, as there was no deformity and but little pain, he had considered the possibility of curetting the carious bone. An incision was made beside the twelfth dorsal, guided by the end of the probe. The transverse process of the twelfth was carious and was cleared away with a bone curette. This instrument was then worked into the body of the bone alongside the spinal dura, without injury to the latter, and a large excavation of softened bone removed, when on every side the curette encountered firm and apparently sound bone. The entire course of the pus tract through the soft parts was curetted and douched with sublimate solution, and finally with a solution of iodoform in ether. In six weeks the patient was sent home with only a slight discharge, and with but one sinus. The course of this case showed that where there were sinuses connected with a small carious bone focus, the great proportion of purulent secretion was from the sinus walls, uniformly lined with tubercular granulation. It further illustrated the ease with which the excavation and drainage could be accomplished directly backward through the side of the vertebral canal, pressing the uninjured dura one side.

Case V. *Extradural Tubercular Tumor of the Spine, with Complete Paraplegia; Operation; Recovery.*—Patient presented. Male, aged twenty-two years, was taken with a pain in his back in January, 1888. The spine was flexible and without deformity, with the exception of a slight fullness in the soft parts to the right of the ninth and tenth dorsal spines. During March sensation was diminished in the legs and muscular power weakened. A line of hyperæsthesia formed about his waist. Two weeks later he could not stand without support, and he had uncontrollable twitchings of the legs, which had become quite anæsthetic. He also had constant intercostal pain, with girdle pains about the limiting line of disease. Incontinence of urine and fæces followed. An active hectic now set in, and the patient wasted rapidly. In May, just two years ago, operation was performed; the spines and arches of the eighth, ninth, and tenth dorsal vertebræ were removed. Outside the carious arches of the ninth was half an ounce of thick pus, but within and filling the vertebral canal was a small quantity of inspissated pus and a large amount of neoplasm, evidently tubercular. It extended upward and down the canal for two inches and a half, and was thoroughly curetted from the cord. The usual dressings were applied. On the eighth day sensation began to return, and then he could move his legs. From this time on recovery was uninterrupted, with the exception of a sinus which the speaker still hoped to heal.

Case VI. *Pressure Paraplegia from Extradural Sarcoma.*—Male, aged forty-two years. The patient had always enjoyed good health. Three years ago, while placing a pedal under a heavy piano, the instrument had been let down and pressed heavily on his back. After this he had suffered pain for several days. Six months later, while lifting the corner of a piano, he was caught by an excruciating pain in the back. No further trouble ensued at this time. About July 1, 1889, he had jarred his spine severely. A week later he had again jarred himself by slipping on the ice and plunging forward on his hands and knees. In this same month he began to fail in health and have pain in the back. His bowels became difficult to move, and it required great effort to empty the bladder. At the end of five weeks he had found it difficult to guide the limbs. There was no high temperature. In the latter part of August paraplegia and insensibility were found to be complete. In October, 1889, the diagnosis of pressure paraplegia was made and an early operation advised. In January, 1890, the patient had come to New York and was advised a month or six weeks' orthopædic treatment, hoping that the pressure might be from Pott's disease and that a natural relief of intervertebral pus might soon be expected and the paraplegia cured without operation. The looked-for improvement did not come; he grew rapidly worse. The following two weeks he had suffered with an acute nephritis and a temperature of 102 5° F. On March 20th, the day before it had been arranged to operate on him, he had an unaccountable chill, with a temperature of 104·6°. This attack lasted over two weeks before his temperature fell to normal. During this time the urine showed twenty per cent. of albumin and various casts. There were no pulmonary complications, but

deep ulceration of the rectal wall was found which was healed under iodoform. On April 16th, the patient being in fair condition, operation was performed. An incision was made from the seventh to the eleventh dorsal spines. The arches of the eighth and ninth, as well as the base of the spine of the eighth, were found somewhat crumbly and eroded by a softish dark growth which disintegrated the bone where it pressed outward from the vertebral canal. The bone was unusually porous in the neighboring parts, not immediately involved in the tumor, and bled freely. On removing the arches of the eighth, ninth, and tenth vertebræ and the pedicle of the eighth, a firm dark growth was found to fill the vertebral canal, flattening the cord to half its normal size. The tumor stopped abruptly at the ligamentum subflava above the eighth and extended downward an inch and a half. It was readily removed, leaving the dura with quite a normal appearance. Not a trace of pus suggestive of tubercular caries was seen anywhere. The wound was dressed with iodoform gauze, no plaster jacket being used. The operation was endured very well, but hiccough and vomiting set in and could not be relieved, the patient dying on the ninth day. A careful examination of the tumor found it to be a round-cell sarcoma without a trace of leucocytes, giant cells, or tubercular material.

Case VII. *Intractable Brachial Neuralgia.*—The patient, a man forty-four years of age (presented), had suffered for two years with intense neuralgia of the right brachial plexus appearing in the forearm and hand. It had grown worse, until the hand became disabled and the muscles atrophied. As the posterior interosseous and ulnar nerves had been stretched without abatement of pain, the arm was removed at the deltoid insertion in the humerus. This did not improve the condition; the patient felt as if the hand and wrist were still on. The possibility of the pain being caused by a tumor or inflammatory process near the origin of the nerve roots led to the following operation. The arches of the fourth, fifth, sixth, and seventh cervical vertebræ were removed, exposing more than two inches of the cord. No tumor or abnormity was felt. The speaker then drew back the roots of the sixth and seventh nerves from the intervertebral foramina into the vertebral canal, and then cut them across just outside the dura, where the sensory and motor roots join. The wound was lightly packed with gauze. Recovering from the anæsthetic, he still suffered pain, seemingly in the fingers. This region was supplied by the eighth cervical nerve. Forty-eight hours after the operation, with the patient prone, the dura was split up for an inch and a half, letting out two ounces of spinal fluid. This was painless, the patient not being under an anæsthetic. The speaker now picked up the posterior roots of the eighth nerve within the dura, which was at the same level as the seventh outside, and cut a quarter of an inch from it. Handling the nerve gave the patient the same pain he had complained of for the past two years. The dura was sutured with catgut; union was perfect. The pain entirely changed in character; it no longer went down into the fingers, but seemed to draw the stump. The pain had continued to be paroxysmal, and was quite severe at times. The skin was anæsthetic from the acromion process downward on the entire outer side of the arm. There was partial anæsthesia of the anterior and posterior aspect of the arm, and over the shoulder from the middle of the clavicle to the middle of the scapula, while the skin facing the axilla was rather hyperæsthetic. This condition had remained unchanged up to the present time, a year and four months since operation, and the patient thought that he had as much pain as before the operation, and had gone back to taking a grain of morphine daily.

Case VIII. *Intractable Neuralgia.*—G. Z., aged forty-five, in 1886 had suffered with a "drawing pain" on the ulnar side of the hand, continuing for two months. It was of such severity that he was obliged to give up his business. The following year the nerve had been stretched, but the pain had grown worse, extending over the hand and forearm. The nerve was then excised, resulting in an exaggeration of the pain. The nerves of the brachial plexus were now stretched in the axilla, but without a relief from the symptoms. After the first operation the forefinger became drawn backward and the forearm wasted. In February, 1889, the patient had come under the speaker's care. It was thought possible to bring about sensory anæsthesia by operation upon the sensory roots of the brachial plexus. Incision was made to the left of the spinous processes from the third cervical to the second dorsal vertebræ. The laminæ of the fifth, sixth, and seventh and first dorsal vertebræ were cut away, exposing the dura. Nothing abnormal was found. The dura was slit up for two inches and a half. The cord was slightly congested. The posterior roots of the sixth, seventh, eighth, and first dorsal nerves were lifted up and divided close to the cord; the free ends were caught up and a quarter of an inch exsected. The wound was closed as usual. The patient's general health had improved, but there was still pain in the wrist, though not so severe as before the operation. The pathologist's report of the exsected nerve roots said that inflammatory exudation was quite marked around the root of the first dorsal. The basis for this operation was the fact that sensory conduction was isolated in the posterior root, which was easily operated on within the dura. Experiments showed that speedy and complete degeneration backward into the cord followed this section. It was the speaker's conviction that if all five roots had been cut, in his cases, the chance of recurrence would have been less. The speaker closed his remarks by emphasizing the advantage of the method as adopted by him. It was the most speedy and the least bloody. It preserved all the tissues in and about the spines which were replaced, and gave firmness to the back, as well as preventing a gap that Nature must fill. While we were not warranted in taking a sanguinary view of the results of operation, yet surgery, with its possibilities ever looming up, ought not to occupy the ultra-conservative ground of the past in this field.

Dr. J. A. Wyeth thought the region of the eleventh and twelfth dorsal vertebræ evidently the site most prone to injury by direct violence. He suggested that the cases calling for surgical interference should be divided into (1) those resulting from pressure upon the cord by bone, whether gradual, as in Pott's disease, or from destruction by sudden violence; and (2) compression by intradural or extradural growth. The simplest form was that of the extradural growth. These tumors were easily approached by removal of the laminæ. Tumors or the cord were more dangerous and recovery less sure. Of pressure by bone, that in Pott's disease was less severe, while that from fracture was practically incurable so far as complete recovery was concerned. He did not think that the operation of resection of the cord and the reunion of the ends would accomplish much unless they adopted the extreme measure of taking out the body of a vertebra and letting down of the superimposed structures wholesale.

The speaker then narrated in brief the remarkably satisfactory results in a case of his already recorded, in which complete recovery had followed operation for compression. The patient had been hopelessly bedridden for two years. The site of the operation had been from the fourth to the sixth dorsal vertebræ. In the second case there had been fracture at the eleventh dorsal. The result of operation had not been very encouraging. The speaker believed the field of spinal surgery to be larger than at present anticipated.

Dr. A. G. Gerster thought the intervening cicatricial tissue would prevent restoration of function in case of division of the

cord. Operative interference seemed justifiable because of the utterly hopeless character of these cases without it, and surgical measures might be productive of good, and certainly served the purpose of investigation. He would not hesitate to resort to the extreme measnre suggested by Dr. Wyeth, provided it had been demonstrated by experiment that reunion of the ends of a divided cord would result in restoration of its physiological integrity.

Dr. B. Sachs, speaking from the standpoint of a neurologist, did not think the recorded results in this particular field of surgery had been very encouraging. He thought surgeons might use more care in the selection of their cases for operation. Dr. Abbe had demonstrated very decidedly the good results that might be obtained in tubercnlous cases, a type which had been considered as by no means amenable to operation. He did not think so many laminæ need be removed. Operations on the spine for neuralgias he deprecated.

Dr. Abbe said that no one would think of operating on the cord in neuralgic cases except as a last resource. He did not advocate operation in cases of fractnre. He thought any attempt to reunite the cord by the removal of a vertebra would destroy the patient's life.

Book Notices.

Essentials of Gynæcology. Arranged in the Form of Questions and Answers prepared especially for Students of Medicine. By Edwin B. Cragin, M. D., Attending Gynæcologist to the Roosevelt Hospital, Out-patient Department, etc. With Fifty-eight Illustrations. Philadelphia: W. B. Saunders, 1890. Pp. viii–17 to 192. [Saunders's Question Compends, No. 10.]

Books like this one are useful not only to the student who is barely at the threshold of professional life, but to the busy practitioner as well, who can not always afford the time for the prolonged discussions of systematic treatises. There is many a time when one wants facts, pnre and unadulterated, and these compends, *multum in parvo*, when well prepared, as this one seems to be, are often of more service and of wider scope than their authors expect.

The Bradshaw Lecture on Colotomy, Lumbar and Iliac, with Special Reference to the Choice of Operation. Delivered before the Royal College of Surgeons, of England, December 5, 1889. By Thomas Bryant, F. R. C. S., M. Ch. (Hon.) Roy. Univ. I., etc. London: J. & A. Churchill, 1890. Pp. 47.

Mr. Bryant believes firmly that lumbar shonld be preferred to inguinal colotomy, and he presents in this lecture his answers to those who have objected to the lumbar operation, while he emphasizes the objections to colotomy and its incident dangers. He presents his argument fairly and forcibly, and has made a valuable addition to the literatnre on this subject.

Hand-book of Obstetrical Nursing, for Nurses, Students, and Mothers. Comprising the Course of Instrnction in Obstetrical Nursing given to the Pupils of the Training School connected with the Woman's Hospital of Philadelphia. By Anna M. Fullerton, M. D., etc. Philadelphia: P. Blakiston, Son, & Co., 1890. Pp. viii–16 to 214. [Price, $1.25.]

Women have a knack of remembering the forgotten things and instituting small reforms that are great reforms. Dr. Fullerton's hand-book is an illustration of this. Law, order, and comfort rob childbirth of half its terrors. What thoughtfnl woman has not longed for the quiet cave of the prehistoric savage in place of the trivial confusion, lace and ribbons, and distracting petty cares that accompany the parturient state in modern homes? If the simple directions in this little book could always be carried out, the lot of average womankind would be greatly ameliorated.

Mother, Nurse, and Infant: a Mannal especially designed for the Guidance of Mothers and Monthly Nurses. By S. P. Sackett, M. D. New York: H. Campbell Co. Pp. 378.

This book is full of negations, a series of doleful "don'ts," instead of the cheerfnl affirmation and positive directions that the subject requires. There are chapters devoted to remedies and regimen and to a medical formulary, and a glossary that is altogether unique. According to this glossary, the Falloppian tubes are two ducts or tubes floating in the abdomen. Query: whose abdomen? The following remedy shonld never be forgotten: "For stranguary, use bee-tea, made by pouring a pint of boiling water on fifteen or twenty honey-bees." It is quite possible that *Mother, Nurse, and Infant* may meet with a certain sale, for it appears to dispense that dangerous commodity, a little learning. The mother, nurse, or infant who cares to read of the primitive streak of von Baer, the false amnion of Pander, the A_1 or A_4 position, etc., will find them all referred to. In fact, there are too many things referred to; hence the lack of value in these three hundred and seventy-eight pages.

Experimental Studies relating to the Action of Hyoscine Hydrobromate, Nitroglycerin, Hydrocyanic Acid, etc., and certain Physiological Conditions, npon the Circulation of Blood in Man as shown by the Sphygmograph. By Arthur C. Hugenschmidt, of Paris, France. (Presented on March 15, 1887, before the Faculty of the Medical Department of the University of Pennsylvania for the Degree of Doctor in Medicine.)

This monograph is interesting so far as it goes, and it is to be hoped that the author will continue his studies in more detail. The sphygmographic tracings show much skill in the use of the instrument, which is not one of precision, but only one of *decision* in the hands of an expert. The author calls attention to the effects of deep respiration on the blood pressure, etc., and gives some interesting tracings showing the effects of food as well as of the drugs mentioned. He makes no generalizations, but presents certain facts clearly and concisely, and his work is therefore of value.

Chronic Bronchitis and its Treatment. A Clinical Study. By William Murrell, M. D., F. R. C. P., Lectnrer on Pharmacology and Therapeutics at the Westminster Hospital, etc. Philadelphia: P. Blakiston, Son, & Co., 1890. Pp. 176.

This is a practical book by a practical man. It is written in a way that shows a keen appreciation of the differences not only of cases, bnt of individual hnman beings. The histories given are told with charming frankness, and the writer's comments on patients' statements are delicions. He addresses English physicians and speaks of English patients, bnt the American physician may learn much of practical value from his work, and must also appreciate, more than most Englishmen, the quaint, half-humorous common sense of the book.

A Manual of Anatomy for Senior Students. By Edmund Owen, M. B., F. R. C. S., Snrgeon to St. Mary's Hospital, London,

etc. With Numerous Illustrations. London and New York: Longmans, Green, & Co., 1890. Pp. viii–526. [Price, $3.50.]

This work is more than its name implies. A practitioner is frequently in need of a book which will supply him with such anatomical information as is essential for his successful and intelligent work, without a wearisome mass of detail. Mr. Owen has successfully attempted to supply this need and has furnished us with a manual of practical anatomy—practical not alone from a surgeon's point of view, but from a physician's as well. It is written in a pleasant, readable style, and its only fault is its size—it might profitably be twice as large. As it is, it is a *multum in parvo* well worthy of a place in every practitioner's library.

Leçons sur les maladies du larynx. Faites à la Faculté de médecine de Bordeaux (cours libre). Par le Dr. E. J. Moure, Professeur libre de laryngologie, otologie et rhinologie, etc. Recueillies et rédigées par le Dr. M. Natier, Ancien chef de clinique du Docteur E. J. Moure, et revues par l'auteur. Avec des figures en noir dans le texte. Paris: Octave Doin, 1890. Pp. iv–599.

This volume comprises forty-seven lectures, delivered in the course on laryngology by the editor of the *Revue de laryngologie*. The lectures naturally avoid the unnecessary presentation of conflicting views, while each subject receives thorough consideration. Tuberculous and syphilitic laryngitis are especially noticeable for the thoroughness of their presentation, and no text-book on this subject excels the chapters on the nervous diseases of the larynx. The author has taken advantage of his experience in the recent epidemic to write a chapter on the laryngeal complications of influenza, comprising catarrhal laryngitis, paralysis and spasms of the glottis, and ulcerations and œdema of the larynx.

As a text-book this work has no superior, and we hope to see it translated into English.

BOOKS AND PAMPHLETS RECEIVED.

Recherches cliniques et thérapeutiques sur l'épilepsie, l'hystérie et l'idiotie. Compte rendu du service des enfants idiots, épileptiques et arriérés de Bicêtre pendant l'année 1889. Par Bourneville, médecin de Bicêtre, Sollier, conservateur du musée de Bicêtre, et A. Pilliet, ancien interne du service. Volume X, avec 22 figures dans le texte et une planche chromo-lithographique. Paris: Lecrosnier et Babé, 1890. Pp. lvi–188. [Publications du *Progrès médical.*]

The Physician's Companion: a Pocket Reference-Book for Physicians and Students. By Clarence A. Bryee, M. D., Editor of the *Southern Clinic*, etc. Richmond, Va., 1890. Pp. 160. [Price, $1.]

The Intestinal Diseases of Infancy and Childhood. Physiology, Hygiene, Pathology, and Therapeutics. By A. Jacobi, M. D., etc. Vols. I and II. Second Edition. Detroit: George S. Davis, 1890. [The Physician's Leisure Library.]

Transactions of the New York State Medical Association for the Year 1889. Volume VI. Edited for the Association by Edward K. Dunham, M. D., of New York County.

The Sewerage of Columbus, Ohio. Address of Colonel George E. Waring, Jr., at Board of Trade Auditorium, Columbus, Ohio, Monday, June 23, 1890, and Discussion following.

I. A Case of Corneal Transplantation from the Rabbit's to the Human Eye. II. A Singular Case of Injury. By William F. Smith, M. D., Chicago. [Reprinted from the *Archives of Ophthalmology.*]

Anthrax: the Disease of the Egyptian Plagues. By Henry William Blanc, M. D., New Orleans. [Reprinted from the *New Orleans Medical and Surgical Journal.*]

Lectures on Massage and Electricity in the Treatment of Disease (Masso-electrotherapeutics). By Thomas Stretch Dowse, M. D., Fellow of the College of Physicians of Edinburgh, etc. New York: E. B. Treat & Company, 1890. Pp. xix–379. [Price, $2.75.]

Beiträge zur Augenheilkunde. Von Professor R. Deutschmann, in Hamburg. 1. Heft, mit 10 Abbildungen in Text. Hamburg und Leipzig: Leopold Voss, 1890. Pp. 80.

Drs. Bourneville and Bricon's Manual of Hypodermic Medication. By G. Archie Stockwell, M. D., F. Z. S. Detroit: George S. Davis, 1890. Pp. 158. [The Physician's Leisure Library.]

Reports on the Progress of Medicine.

GENERAL MEDICINE.

By S. T. ARMSTRONG, M. D.

Intestinal Charbon in Man.—Dr. G. Bouisson makes a rare case of intestinal charbon in man the subject of a Paris thesis this year. The patient was a tanner, and when brought to the hospital was suffering from abdominal pain, swelling, vomiting, and algidity, that seemed to be caused by intestinal strangulation. Death resulted; and at the necropsy ecchymoses were noticed on the peritoneal surface of the intestines as far as the termination of the jejunum. At this point the intestine was so thickened that the lumen of the canal was diminished one half; this was due to an intestinal thrombus extending more than twenty centimetres, and existing less extensively elsewhere. The ecchymoses were all situated at the mesenteric border of the intestines, and were limited to the small intestines, mesentery, and adjacent lymph glands. They extended through the wall to the mucous surface of the intestine, attaining a thickness of about one centimetre, and, seen from the surface, seemed to be a simple infiltration of blood. Microscopically, sections of the ecchymotic foci were found to contain numbers of the charbon bacilli that were present only in the most superficial portion of the intestine and were not present in the deeper portions of the mucous or in the muscular layers. Cultures and inoculations demonstrated that the micro-organism was the charbon bacillus.

The Contagiousness of Tuberculosis.—According to *Le Progrès médical*, Dr. Haupt, of Soden, has endeavored to demonstrate that the contagiousness of tuberculosis is very dubious. The observations that have been made at the baths of Soden are very interesting. Of the 1,500 inhabitants of the place, 101 keep boarders; and usually these women, with their sisters and daughters, nurse their phthisical guests. In some of the houses the women are assisted by nurses from some neighboring village. They make the patients' beds, sweep and dust the rooms, remove the sputa, and generally work exposed to the contagion. In winter the family of the boarding-house keeper occupies the same rooms used by consumptives during the summer. From 1855 to 1888, 48 of 238 boarding-house keepers died; 10 of the deaths were from tuberculosis, and in 6 of these there was a hereditary predisposition; in the other 4 cases the disease was caused by external causes. Of 415 nurses, 17 had died; 5 of the deaths were tuberculous. In the three past years there were 76 deaths in Soden, 7 of them caused by tuberculosis, 2 cases being meningeal and 1 osseous, each of these in infants. The 4 remaining deaths were not of persons employed in the houses.

The Processes taking Place in the Diphtheritic Membrane.—Dr. M. A. Ruffer concludes, in a paper in the *British Medical Journal* of July 26th, that: 1. The bacilli of diphtheria are present in the most superficial part of the membrane only; that is, in a place where they are well within reach of medicinal agents—an observation not without interest from the point of view of treatment.

2. In the diphtheritic membrane there is an active struggle taking place between the amœboid cells in the membrane and the micro-organisms. In other words, the diphtheritic membrane is a battle-field for amœboid cells and the pathogenic microbes of diphtheria.

3. The reason why the bacilli do not actually penetrate into the tissues is probably that as soon as they try to do so they are arrested by the amœhoid cells present in the diphtheritic membrane.

The Treatment of Scarlatina by Acetate of Ammonium.—Dr. Vidal, in a paper read before the Paris Academy of Medicine, concludes, according to *Le Mercredi médical* of August 6th, that there is hut little douht that acetate of ammonium is perfectly tolerated hy children in doses of fifteen grains for each year of their age, and to adults as high as an ounce a day may he administered. In these doses acetate of ammonium rapidly reduces high temperature, thus making it a desirahle remedy in the treatment of scarlatina, and perhaps also in the other eruptive fevers. The action of the medicament is most rapid if it is administered at the commencement of the disease.

The Treatment of Whooping-cough with Antipyrine.—Dr. P. Ree, in the *Deutsche med. Woch.*, No. 19, 1890, states that whooping-cough may he ahorted by antipyrine if administered at the heginning of the convulsive state, on the third or fourth day following the appearance of the paroxysm of pathognomonic coughing. The dose of antipyrine should he one grain and a half for each year of the child's life, administering such a dose three times a day after eating; the drug is easily tolerated by the child, the author never having seen any intoxication following its use. At a later period in the disease antipyrine has no action on the process. It is generally noticed that if the cough suddenly ceases, broncho-pneumonia supervenes, the cough reappearing with greater intensity on the cessation of the hroncho-pneumonia. If in the course of whooping-cough the paroxysms of coughing suddenly cease, Priessnitz's compresses should he applied to the chest, and a mixture of benzoic acid and camphor (of each half a grain three times a day), or tincture of ipecac, should be administered to avert the pneumonia.

Vaccinial Fever.—Dr. Peiper, in the proceedings of the *Soc. méd. de Grieswald* for January 10th, reports twenty-three cases of vaccinial fever in children. In six cases the fever appeared during the third day, attaining a temperature of 39·6° C. Generally it developed hetween the fourth and seventh day, attaining the highest temperature (40° C.) on the seventh or eighth day. It lasted from two days and a half to four days and a half, and did not depend on the numher of pustules, nor upon the intensity of the local inflammation. In six cases of revaccination the author discovered hut two cases of fever. The fever is rarely important; and when it is very high or prolonged, complications must be feared.

A New Treatment for Epilepsy.—According to *Le Mercredi médical* of July 30, 1890, Laufenauer has employed for all epileptic conditions except hystero-epilepsy the hromide of ammonium and rubidium. He commences with a dose of thirty grains, increasing to seventy-five grains, though two drachms a day usually suffice. His formulary is:

℞ Bromide of ammonium and ruhidium..... ʒ jss.;
Syrup of lemon..... ʒ v;
Water..... ʒ x.

The Tests for Stomach Acids.—In his paper on the pathology of gastric dyspepsia in the *British Medical Journal* of August 9th, Mr. D. J. Hamilton gives the various tests for the acids contained in the gastric juice. In cases of acid dyspepsia, an hour after a meal starch will not have changed into maltose and dextrin, and iodine will produce the blue coloring. But, as maltose changes into grape sugar chiefly in the small intestine, it is probably the transformation of cane sugar into dextrose and thence to lactic acid that causes the large proportion of the latter during ahnormal digestion.

After a test meal the liquid is drawn off with a stomach tube and filtered, and the total acidity ascertained by any of the usual methods. Then fifty cuhic centimetres of the filtrate are distilled until three fourths of the quantity have passed over, when fifty additional centimetres are added and the distilling proceeded with for the same amount as before. The volatile acids are carried off and may he quantitatively estimated by the titration methods; the residue in the retort is shaken up with ether to dissolve out the lactic acid, the ethereal solution is separated by a Geissler's funnel, and the liquid remaining contains the hydrochloric acid and acid salts (phosphates).

To estimate the quantity of lactic acid, evaporate the ether, dilute the residue with distilled water to fifty cuhic centimetres, and neutralize this with as many cubic centimetres of a decinormal solution of sodium hydrate (caustic soda, 0·004 gramme in each cuhic centimetre) as necessary, using litmus to indicate the neutralization. Each cubic centimetre of the sodium-hydrate solution will neutralize 0·009 gramme of lactic acid; so multiply this decimal by the number of cubic centimetres of the sodium solution, and the product will be the quantity of lactic acid in fifty cubic centimetres.

The residue containing the hydrochloric acid is neutralized in the same way, one cuhic centimetre of the test solution neutralizing 0·00364 gramme of hydrochloric acid; this decimal is multiplied hy the number of cubic centimetres of the neutralizing fluid, and the product is the quantity of free hydrochloric acid in fifty cubic centimetres.

Tropæolin in saturated watery or alcoholic solutions changes from a hrown or golden-red color to a ruby-red color in the presence of minute quantities of free hydrochloric or lactic acid, while the hasic, neutral, and acid salts of these or phosphoric acids convert the color into a straw-yellow.

Hydrochloric acid may he detected hy Rheoch's test: a saturated solution of a neutral acetate of iron is added to two cubic centimetres of a ten-per-cent. solution of sulphocyanide of potassium until a ruhy-red color is obtained; a few drops of this solution are placed in a porcelain dish, and a hydrochloric-acid solution changes the color to light violet, and eventually hrown. Günzhurg's test for hydrochloric acid is to dissolve two grammes of phloroglucin and one gramme of vanillin in one hundred cuhic centimetres of absolute alcohol; equal quantities of this and the solution containing hydrochloric acid are heated in a white porcelain dish with the formation of a rose-red color if the acid is present; neither organic acids, peptone, nor alhuminous suhstances interfere with its action.

To detect lactic acid, add the solution to fifty cubic centimetres of distilled water containing one drop of liquor ferri sesquichloridi, and a yellow color results if that acid is present. Uffelman's reagent is a fresh mixture of ten cuhic centimetres of a four-per-cent. carbolic-acid solution with twenty cuhic centimetres of distilled water containing a drop of liquor ferri sesquichloridi; the amethyst-hlue liquid hecomes yellow in the presence of one third its volume of diluted lactic acid; hydrochloric acid, phosphates, and alhumin disturb this reaction.

Butyric acid may be detected hy its odor, and one tenth per cent. gives with Uffelman's reagent an ash-gray color. Shaking the stomach washings with ether will dissolve the fatty acids, and if the mixture is thrown into water and a little chloride of calcium added, oil glohules are set free.

In the normal stomach one hour after a meal the total acidity is 0·189 per cent., and there is 0·044 per cent. of free hydrochloric acid.

Von Jaksch, in the *Zeitschrift f. klin. Med.*, Bd. xvii, H. 5, states that the ahsence of free acid, or the existence of slight traces only, in one to three hours after a test meal of pure flesh diet or milk, is significant of severe disturbance of the functions of the stomach. He made a series of experiments to determine the comparative sensitiveness of the different color tests, using Congo-red paper, 6 B. paper, benzo-purpurin, and Günzhurg's and Boas's reagents. The Günzburg reagent was the most reliahle, though this would sometimes fail when even a considerahle amount of free acid was present. So a reliahle color test is yet to he discovered.

A Study of the Chemistry of the Stomach considered as an Element of Diagnosis.—Dr. Hayem, in a paper published in *Le Mercredi médical* of July 23d, states that the methods used to study the chemistry of the stomach, hased on the formation of free hydrochloric acid in the gastric juice, are ahsolutely insufficient. The proportions of chlorine under its diverse forms, especially in its combinations with albuminoid matters, must be estimated; and a meal of eight ounces of black tea—without sugar or cream—and two ounces of dry, white hread is given in the morning. An hour after the repast was commenced, some of the contents of the stomach are obtained hy a tuhe—using no water for washing, but obtaining the sample by expression. If the stomach is not empty in the morning, lavage must first be practiced, and the meal taken one or two hours thereafter. A thorough examination of the expressed fluid is made.

As the result of many examinations, the three following categories are estahlished:

1. Certain dyspeptics have a functional irritation of the stomach characterized at the time by an increase of the chlorides, of hydrochloric acid, and of the total acidity. There is an excess of stomach work, and the condition is called hyperpepsia.

2. In others there is a diminution that may go as far as annihilation of all these constituents; this is called hypopepsia, and occasionally becomes apepsia.

3. Lastly, in a small number of cases, the gastric chemistry is slightly modified; this is a simple dyspepsia, probably caused by nervous or mechanical troubles.

The Causes of Gastroxia (Acid Dyspepsia).—Mr. D. J. Hamilton publishes in the *British Medical Journal* of August 9th a most excellent paper on the pathology of gastric dyspepsia. He concludes that gastroxia—the gastroxynsis of Rossbach—is due to an acid, usually lactic, but in rare cases hydrochloric; though in some cases the acidity is due to lactic acid augmented by the presence of various volatile organic acids. The excess of lactic acid may be a result of prolongation of the natural lactic-acid stage of digestion, or it may be furnished by the grape sugar developed from the sugar in the dietary; a small part of it may be grape sugar resulting from the action of salivary diastase on starch.

The cause of the prolongation of the lactic-acid stage of digestion is the deficiency in hydrochloric acid that ought naturally to replace the lactic acid.

The fermentation of the grape sugar into lactic acid is brought about by living vegetable organisms, always more or less abundant in the stomach. This fermentation is probably due in part to deficiency in the quantity and proteolytic quality of the gastric juice, the carbohydrates consequently undergoing a faulty decomposition while the proteids remain undissolved.

Acidity caused by excess of hydrochloric acid is manifested in two ways: (*a*) Where the acid is secreted in a gush immediately on the introduction of food, and (*b*) where it accumulates in the stomach during fasting. In either case the alkalinity of the saliva is neutralized too soon, and, the digestion of starchy food being hindered, it accumulates in the stomach.

Stomach Washing in Children.—In a paper in the *Bulletin of the Johns Hopkins Hospital* for July, 1890, Dr. W. D. Baker reports the result of his experience in two hundred cases of stomach washing for gastro-intestinal disturbance in children. It quickly relieved vomiting in most cases after the first washing, and in but one case was it necessary to stop milk food in order to check the vomiting. In summer diarrhœa, with retarded digestion and almost constant presence of milk curds in the stomach, the removal of the curds by washing not only gives the stomach rest, but prevents their passage into the intestine with consequent irritation and fermentation. It was also used advantageously in constipation consequent upon a catarrhal condition of the gastro-intestinal canal. In one case of carbolic-acid poisoning it was used successfully. It should not be used in children having heart disease, bronchial or pulmonary troubles.

The washing is done with a soft Nélaton catheter, No. 8, 9, or 10, attached by a short glass tube to a piece of rubber tubing, two feet long, with a two-ounce funnel in the distal end. The child is held, sitting, in the nurse's lap, with the head slightly bent forward; a rubber bib reaches from the neck to a slop pail on the floor. The tube is moistened in warm water, passed into the mouth, and gradually forced into the œsophagus and stomach. Gagging or retching usually stops when the tube enters the stomach, and any contents are usually evacuated through the tube; these should be collected and examined. From one to two ounces of tepid water are then poured into the funnel, held above the level of the child's head; the funnel is then lowered and the stomach contents siphoned out. This process is repeated until the washing from the stomach is clear.

Cannabis Indica in Diseases of the Stomach.—Dr. Germain Sée, in *Le Mercredi médical* of July 30th, concludes that in diseases of the stomach a fatty extract of cannabis indica in doses of one grain, five times a day in a solution, is very serviceable. A greater dose is toxic, and the alkaloids do not produce the same effect. The drug is especially useful in inorganic diseases of the stomach, in which there are chemical alterations of the gastric juice (hydrochloric superacidity is most frequent), and in the neuroses that are manifested without chemical modification of the gastric juice. In dyspepsia manifested by troubles of the appetite, flatulence, alterations in digestion, and reflex nervous troubles (cardiac or cerebral), cannabis indica acts in a constant manner to quiet the painful sensations and re-establish the appetite. If these depend on hyperacidity, the drug should be associated with large doses of bicarbonate of sodium at the end of gastric digestion.

Cannabis has no action on spasms or dilatations of the stomach, but it relieves spasms and vomiting due to disorders of the motor nerves. It calms the painful sensations of pyrosis—due to gas from fermentation.

Gastric digestion is increased by cannabis when it is relaxed by a paralytic condition or painful from superacidity. It does not improve indigestion due to absence of hydrochloric acid. The drug improves reflex nervous troubles, but it does not change the nervous disposition of hypochondriacs, hysterical persons, or neurasthenics. Its use demands the aid of other curative methods—alkalies, purgatives, and diet. [*L'extrait gras de haschisch* of the French pharmacopœia is made by the Arabs by boiling the flowers of the fresh plant with butter and a little water; the latter is evaporated, and when the butter is sufficiently charged with the active principle it is ready for use. The preparation is unctuous, tenacious, of a yellow-green color, and nauseous odor.]

Infectious Icterus, or Weil's Disease.—Dr. Ducamp, in the *Revue de médecine* for June, says of this disease that it seems to be identical with the essential icterus of Ozanam, the pseudo-grave icterus of Grellety Bosviel, the icteric fever of Lancereaux, the hepatic typhus of Landouzy and Mathieu, the curable grave sporadic icterus of Roudot, and the infectious icterus of Bernheim. So, although Weil's name has been given to the disease, it was clearly described by Landouzy three years previous to Weil's paper.

Dr. Ducamp's cases occurred in three of six laborers engaged in cleaning a foul obstructed sewer in Montpellier. The slime was disinfected by chloride of lime; but all of the workmen became ill—three of them with infectious icterus, two with gastro-intestinal troubles, and one with simple malaise. There were no other cases of icterus in the street, city, or hospital, and the men affected did not live in the same part of the city. The condition seemed grave and persistent, and was accompanied by moderate fever, pronounced myalgia, and a marked icterus (polycholic) that disappeared slowly during a long convalescence. Infectious icterus, like all infectious diseases, has a period of incubation that makes no manifestation in the midst of perfect health; a period of invasion when there is no presage of the disease that will appear; at last a period of activity, and lastly that of decline. In these cases the period of incubation was five days. The period of invasion was marked by a severe general condition, extreme fatigue, moderate fever, severe myalgia exaggerated by pressure on the muscles of the inferior limbs, and occasionally vertigo and epistaxis. The period of activity is particularly marked by an intense polycholic icterus, albuminous urine in one case, occasional nasal and cutaneous hæmorrhages, the gravity of the general condition of the case above all attracting attention. The period of decline is announced by a diminution of icterus; it is of long duration, and there may be slight diminution in the volume of the liver. The disease he regards as of microbial origin.

The Liver in Typhoid Fever.—Dr. T. Legry, according to the *Rev. des sci. méd.* for July, finds that the liver in typhoid fever is not increased in volume, except rarely, as it is in alcoholism, puerperal fever, malarial poisoning, and in long-continued diseases. The pale and grayish color often erroneously suggests a well-marked fatty degeneration. The bile is generally pale, decolorized, less abundant, and of feeble density. By microscopic examination a granulo-fatty degeneration is found that is very slight at the commencement of the disease, and only more extensive in cases of late death or of complication; the degeneration is always less pronounced than the macroscopic appearance of the liver indicates. The lesion is sometimes circumportal and circumlobular, more rarely perihepatic, or altogether peripheric and central; it is characterized by the presence of fine granulations, that may become confluent, forming more voluminous droplets, but rarely attaining the size of the fatty granules in tuberculosis. The capillaries are dilated and full of blood at the commencement of the disease, but

this soon ceases. The cells may present a cloudy tumefaction, more rarely a hyaline and transparent appearance; they always contain many nuclei. In the portal canals nodules made of nuclei, surrounded with protoplasm arising from the degeneration of the hepatic cells, are found; these nodules are due to microbic embolism. The portal spaces often present in places a slight degree of embryonic infiltration.

In eleven cases the presence of the bacillus of Eberth was demonstrated in sections of the hepatic parenchyma, and positive cultures of the bacillus were obtained from the liver tissue. The conclusion is that the liver probably arrests and destroys the microbes that are introduced by the portal vein, that it arrests about half of the toxic substances contained in an alcoholic extract made with typhoid fæcal matter, and that, lastly, it seems also to diminish the toxicity of the soluble products secreted by the bacillus of Eberth.

In ordinary typhoid fever there are no direct physical signs that allow us to appreciate the anatomical condition of the liver, or the degree of the performance of its functions. It is by indirect symptoms, and, above all, by finding urobilin in the urine, that we obtain indications of real value.

The Cause of Hæmatemesis in Hepatic Cirrhosis.—Dr. Litten, in the *Berl. klin. Woch.* of February 3, 1890, states that in five cases of hepatic cirrhosis in which death was caused by vomiting blood it was ascertained that the source of the hæmorrhage was the enormous varices that ruptured in the inferior portion of the œsophagus. Naturally the œsophagus is richly supplied with veins of which the superior communicate, by means of the thyreoid vein, with the vena cava superior; while the inferior form about the cardiac extremity a large plexus that communicates but moderately with the portal vein, and empties principally into the azygos vein. Consequently, as in cirrhosis of the liver the portal vein becomes impermeable, its blood passes in great part into the azygos vein that conducts it direct to the vena cava superior. This is particularly the case with the blood of the coronary and gastroduodenal veins. As a result of the azygos vein becoming distended and incapable of receiving all the blood of the œsophageal plexus, there is a formation of varices with consequent rupture simulating gastrorrhagia.

The Varieties of Hepatic Tuberculosis.—Dr. Hanot and Dr. Gilbert, in the *Archives gén. de méd.* for November, 1890, make the following divisions of tuberculosis of the liver, founded on the existing pathological conditions: 1. The acute form is a fatty hypertrophic tuberculosis of the liver resembling a fatty hypertrophic cirrhosis. 2. The subacute forms, presenting two varieties: *a*, atrophic fatty tuberculous hepatitis; *b*, nodular parenchymatous tuberculous hepatitis. 3. The chronic forms of tuberculous cirrhosis and of fatty degeneration.

Such distinctions, of course, are of chief value in making necropsy reports.

The Cause and Treatment of Diabetic Coma.—Dr. Stadelmann, in the *Deutsche med. Woch.*, No. 46, 1889, states that he has found crotonic acid in the urine in certain cases of diabetes. Minkowski and Küleg believe that this acid results from the decomposition of oxybutyric acid, which should also form acetic acid. It is ou these data that the hypothesis of acid intoxication in diabetic coma rests, as well as the reason for the intravenous alkaline injections. Of eleven cases treated by this method by various physicians, only one patient recovered, though all the reporters agree on the temporary amelioration the injections produce. The injection is made by dissolving 186 grammes of bicarbonate of sodium and 286 grammes of carbonate of sodium in four litres of distilled water. A litre to a litre and a half may be injected in the case of an adult.

The author prescribes for diabetics large doses of tartrate of sodium, as much as forty-five grammes a day having been given without loss of weight or diminution of appetite.

True diabetic coma threatens those only that have oxybutyric acid in the urine; diabetics that eliminate more than 1·1 gramme of ammonia daily run great danger, while those eliminating as much as from two to six grammes are threatened by coma. When the perchloride of iron reaction occurs the presence of oxybutyric acid is affirmed, though the inverse is not always true. When diabetic coma is feared, a rigorous meat diet and large doses of alkalines should be prescribed. When coma exists, intravenous injections of bicarbonate of sodium should be given until the urine becomes alkaline; the subcutaneous injections of soda should not be practiced, because they are painful and incite local suppuration.

The Principles of the Treatment of Diabetes Mellitus.—Dr. F. W. Pavy publishes, in the *British Medical Journal* of August 16tb, the paper he read before the Berlin International Congress. He believes that the first consideration in the treatment of diabetes is to control by dietetic measures the passage of sugar through the system. The real point, however, to be aimed at is to restore the assimilative power over the carbohydrate elements of food; and until this has beeu accomplished it can not be said that a cure has been effected, the disease only being held in subjection and prevented, as long as the condition can be maintained, from progressing to an unfavorable issue. The maintenance of a normal state of the system, by keeping it free from the passage of sugar through it, conduces most to the restoration of assimilative power, and thus a healthy condition of the body is brought to bear to help promote the removal of the faulty state. He believes opium and its alkaloids, codeine and morphine, are the medicinal agents that especially assist in the restoration of the impaired assimilative power, their influence being particularly noticeable in cases in which the sugar has been brought down to a certain point, but not entirely removed by dieting; these drugs will then completely remove the sugar. The quantitative testing of sugar in the urine is absolutely necessary, not only to regulate the treatment according to the progress made, but also to keep a check upon the manner in which the directions given are being carried out.

The Pathogeny of Albuminuria and Nephritis.—At a recent séance of the Academy of Medicine of Paris, Dr. Semmola read a paper in which he concluded, according to *Le Mercredi médical* of July 30th, that—

1. The degree of albuminuria is not always in accord with the intensity of the morbid renal processes. In toxic nephritis produced by agents that have no alterative action on the blood, the maximum of renal lesions and minimum of albuminuria are found, while in toxic nephritis of mineral origin, in general, a maximum of albuminuria occurs that is due both to renal lesions and a dyscrasic condition.

2. In albuminuria produced by the injection of the white of egg only a slight epithelial alteration is necessary. It becomes, therefore, a simple phenomenon of depurative elimination.

3. Such albuminuria is no less than a functional effort to which the renal apparatus does not physiologically tend, for in the normal state the albuminoids received by alimentation are destined to supply the intra-organic functions and not to be eliminated.

4. The eliminative processes produce at length secondary renal alterations that should be classed with toxic nephritis, properly so called, with the difference that in the latter inflammatory lesions predominate, while the former are rather degenerative.

5. The albuminuria of Bright's disease (always characterized by great oscillations in the quantity of albumin excreted at different hours of the day, because of either the richness of alimentation in nitrogenous substances, or of causes that escape us) should be classed among hæmatogenous albuminurias, because, for anatomical and clinical reasons, it would be impossible to conceive of such rapid and frequent changes, in a few hours only, in the alteration of the epithelium.

Arsenite of Copper in Acute Affections of the Intestine.—Dr. H. Schulz, in the *Deutsche med. Woch.*, No. 18, commends Aulde's treatment of acute intestinal diseases by arsenite of copper. The best method of administering the drug is by frequently repeated fractional doses, for children dissolving one one-hundredth of a grain in four to six ounces of water, and giving a teaspoonful of the solution every ten to thirty minutes. It is especially serviceable in recent cases before inflammation of neighboring organs commences; and he has employed it in severe cases of epidemic cholera, cholera morbus, and dysentery. He believes the favorable action of the drug is due to an energetic stimulation of the diseased intestine, and a consequently conferred capacity to resist the pathogenic micro-organisms.

The Results of the Chronic Abuse of Coffee.—Dr. F. Mendel, in the *Berlin klin. Woch.*, No. 40, 1889, says that in the industrial territory of which Essen is the center the working women drink coffee from morning to night, consuming daily for each individual a pound or more

of Ceylon coffee containing on an average four grammes of caffeine to the pound. The morbid phenomena caused by the chronic abuse of coffee are of three kinds:

1. Nervous troubles. A feeling of general weakness, aversion to work, sadness, cephalalgia, and insomnia. All these symptoms disappear more or less when the individual has taken a concentrated infusion of coffee.

2. Muscular troubles. A greater or less decrease of vigor of motion; no more incapacity to accomplish the coarser domestic labors than to do fine hand-work; trembling of the hands, even when at rest.

3. Circulatory troubles. Small, accelerated, irregular pulse; feeble beat of the apex of the heart; præcordial distress; palpitation. Coldness of the extremities, appreciable to the patients. Yellowish-white visage, and anæmia of the mucous membranes. Anorexia is frequent, and there is nervous dyspepsia: a sensation of pressure and of fullness of the stomach, nausea, eructations, cardialgia.

Isaac has called (*Berlin klin. Woch.*, No. 3, 1889) attention to the tendency to acne rosacea.

The treatment is to stop the difficult work done by the patient; to substitute milk for coffee; to keep in the open air; to take daily cold baths followed by energetic friction; and cognac in small doses.

This description will apply equally well to those working women in America who use tea in amounts proportional to the confinement and physical strain incident to their occupation. The treatment would be the same, and can probably be as easily adopted by working women in America as in Germany.

Miscellany.

Mortality in Cities in the United States.—The following table represents the mortality in the cities named, as reported to Dr. John B. Hamilton, Surgeon-General of the Marine-Hospital Service, and published in the Abstract of Sanitary Reports for September 5th:

CITIES.	Week ending—	Estimated population.	Total deaths from all causes.	DEATHS FROM—									
				Cholera.	Yellow fever.	Small-pox.	Varioloid.	Varicella.	Typhus fever.	Enteric fever.	Scarlet fever.	Diphtheria.	Measles.	Whooping-cough.

Treatment of Typhoid Fever by Cold Baths.—"M. Debove, in a paper read at the last session of the Paris Société Médicale des Hôpitaux on the treatment of typhoid fever by cold baths, declared that he had not been convinced by a recent paper of M. Merklen that this was the best treatment. His own mortality during the last six years was 11 per cent., or during the last two years, 9·2 per cent. Now M. Merklen estimates the mortality from typhoid in Paris hospitals treated by cold baths as 9·92 per cent. M. Debove does not prescribe active medication, but believes in keeping up copious diuresis. To this end he supplies his typhoid patients with abundance of liquid, and if the quantity of urine passed does not appear to him sufficient, he 'stimulates the zeal' of the attendants to get the patient to drink more; the total amount of fluid which should be taken daily ought, he says, to be not less than five or six quarts. M. Debove, who does not deny the good effects of baths, suggests that they are probably due to the increased quantity of urine secreted, which, as in the case where diuresis is produced by drinking, carries off the *materies morbi* from the system. According to M. Gérin-Rose, who followed M. Debove, still more successful results may be obtained by carrying out the following indications: (1) To produce intestinal antisepsis by means of naphthol and salicylate of bismuth, (2) to lower the fever by means of very large doses of quinine and warm baths (at 86° F.), and (3) to keep up the patient's strength. Of forty-three patients treated during the last eighteen months in this way, only one died."—*Lancet.*

ANSWERS TO CORRESPONDENTS.

No. 329.—We think you are wrong.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Lectures and Addresses.

CLINICAL LECTURES
ON SOME COMMONLY OBSERVED FORMS OF PULMONARY DISEASE.

DELIVERED AT
THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

BY JAMES K. CROOK, M. D.,
INSTRUCTOR IN CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS, ETC.

LECTURE IV.

Acute Pleurisy with Effusion; Aspiration.—This patient, gentlemen, is Mrs. K. W., aged twenty-eight. She gives a plain and suggestive history, the symptoms beginning at a very recent date. As you see, she is a very healthy-looking, robust woman, and her face gives no indication of disease. She informs us that she was perfectly well until about fourteen days since, when she was seized in the evening with a sharp, catching pain in the left side. She remembers also that she had very cold, chilly sensations for an hour or two before the pain came on, but just afterward she had high fever and perspired freely during the night. The pain was much modified on the morning following, but a short, dry cough had developed during the night. As this cough continued and the pain in the side did not disappear after several days, she deemed it advisable to see a physician, and at that time she came under my observation. On examination I found a slight exaltation of temperature—100° F.—and a pulse of 92. A careful physical examination yielded negative results, save a catching respiration and a limitation of respiratory movements on the affected side. But when the patient called to see me again, after a further interval of four days, I noticed that her respirations were very panting and hurried, and she informed me that her breathing had been getting shorter and shorter for several days past. An examination then disclosed the characteristic physical signs which we shall find so well marked this morning. Her temperature to-day is normal, but we find the pulse-rate to be 95 to the minute. On carefully inspecting the chest, we see that the left side is taking but little part in the respiratory movements. There is also an appearance of fullness on that side. Palpation shows a complete absence of vocal fremitus almost from the left clavicle above to the bottom of the chest below. I can feel the apex of the heart a little to the right of the sternum, which shows a displacement of at least three inches. Mensuration shows a preponderance of two inches of the left side over the right. On percussion, I find complete flatness, both before and behind, all over the left side. Even over the clavicle there is total absence of resonance. When I apply my ear to the chest I find a complete absence of the respiratory sounds. The voice sounds are distant and muffled. The physical signs in this case are not to be mistaken. Our patient is suffering from acute pleurisy, with an enormous effusion into the left pleural cavity. If we could have seen the patient during the first twenty-four hours of the trouble, we should probably have heard a grazing friction sound on the left side. At that time the natural moisture of the inflamed portion of the pleura was dried up and the vessels were enlarged and swollen. The visceral and parietal layers of the membrane then coming in contact and rubbing against each other would produce this grazing noise, which would indicate the first or dry stage of the disease. This sound disappears as soon as the exudation begins to form, so that a physical examination during the second or third day, or before the fluid accumulates in sufficient quantity to be recognized, is apt to lead to rather negative results. The exudative products are of two kinds—a serous fluid, which gravitates to the dependent portions of the cavity, and a plastic or fibrinous material, some of which also sinks to the bottom of the pleural cavity, but most of which adheres to the pleura. The membrane, both above and below the level of the fluid, is sometimes enormously thickened by this means, so that it is often impossible to make out the exact surface line of the effusion. In empyema there are abundant pus cells present. The fluid in this case has continued to increase until the left side is filled as high up as the clavicle. The heart, as we have seen, is pushed far out of its place. The left lung is crowded to the upper and back part of the chest against the vertebral column, and is receiving very little if any air. If a further accumulation should take place, the other lung will also very soon become embarrassed in its action and the patient's condition will become greatly aggravated. If the fluid should remain long in the chest, the lung on the affected side will become solidified or carnified, as it is termed, and will be rendered permanently crippled. The heart also may be so seriously interfered with as to threaten the life of the patient. Now, under these circumstances, what are the indications? If the amount of the effusion were slight, say extending up to the level of the inferior angle of the scapula, I should rely upon Nature to remove the fluid and aid it by means of hydragogue cathartics, diuretics, and diaphoretics. But in cases like this, where the effusion is considerable in amount, we simply waste time by this method of treatment. I have spoken of this as an acute case because it is of recent origin, but it will inevitably become chronic unless we take active means to relieve the patient.

In my opinion, aspiration or the operation of thoracentesis should be performed without delay in all such cases. By withdrawing a greater part of the fluid, Nature will in many cases continue the process and the remainder will be absorbed. If we allow it to remain, we expose our patient to all the danger and distress of embarrassed breathing, an impeded heart, and a carnified lung. At the same time, the continued presence of the fluid favors so heavy a plastic deposit upon the pleural surface as to seriously modify or destroy its absorptive power. It has been my experience that aspiration performed within two or three weeks after the inception of the disease is almost invariably successful and requires no repetition; whereas, if the fluid is allowed to remain longer, the operation must be repeated two, three, or perhaps more times. In one neglected case which came under my observation in the summer of 1887, I found it necessary to withdraw the

fluid on seven different occasions. We will now proceed to operate in this case. The instrument I employ is a Potain bottle aspirator. There are as many as twenty-five or thirty aspirators in use constructed on the same principle, but I regard this as one of the best. Having bared the dorsal aspect of the thorax, I direct the patient to sit with her arms folded in front of the body in a slightly stooping position. In cases of great nervousness, or fright, or weak heart, it is not a bad plan to perform the operation with the patient in the recumbent posture and administer an ounce or two of brandy with a little aromatic spirit of ammonia beforehand. I now look for an intercostal space below the angle of the scapula on the left side. It is rather difficult to find one in this patient, as she is rather stout and the ribs are not widely separated. The seventh, being the first and usually the most prominent interspace below the scapula, is the one I usually select, and into this I shall now insert the needle. I select one of medium size for this purpose, having previously treated it with carbolized oil and passed an antiseptic solution through it. I now press the forefinger of my left hand into the interspace and draw the skin slightly aside. This leaves the skin somewhat tense, and when the needle is withdrawn a valvular puncture will remain which absolutely excludes all air. I now introduce the needle, being careful to keep it in the middle of the interspace and particularly avoiding the *lower margin of the upper rib* for fear of wounding the intercostal artery. Having passed the needle in to the depth of an inch and a half, I pump the air from the receiving bottle and turn the stopcock. There is an immediate flow of fluid which, as you see, is of an amber or straw color and not turbid. Having positively demonstrated the presence of an effusion, we are justified in pushing the needle to a greater depth if required, as the heart and left lung are displaced far out of harm's reach. This fluid confirms our diagnosis of simple fibro-serous pleurisy. If it were purulent it would be more viscid and cloudy. I allow it to flow away until three bottlefuls, almost three quarts, are discharged. As the patient is now beginning to feel a sensation of tightness or constriction, I desist. This should invariably be done as soon as such symptoms appear. Other warning events are the occurrence of coughing, coldness of the extremities, shortness of breath, or a weakening of the pulse. We are advised by the text-books that patients should always lie in bed for twenty-four hours after the operation. This can certainly do no harm, but I do not regard it as necessary or even desirable, unless the patient is in a very weak and run-down condition. I have frequently aspirated patients at the clinics and in my office and allowed them to walk or ride to their homes just afterward without the occurrence of any harmful manifestations. The dangers from aspiration of the thorax have been greatly magnified in the past. No doubt more or less harm has been done by means of the old-fashioned trocar and cannula, but I consider the danger in the use of such an instrument as we have here to be almost infinitesimal. The fluid is withdrawn slowly enough to allow the viscera which have been displaced to approach their normal positions gradually and without shock. A considerable time must elapse after the operation before there is a complete reposition. This slow withdrawal also obviates to a great extent the œdema of the lungs and syncope which have been observed under the use of the trocar and cannula. The after-treatment in this case will consist simply in the observance of careful dietetic and hygienic rules, with the administration of a little digitalis and acetate of potassium to stimulate the heart's action and promote free diuresis. It is entirely probable that the small quantity of fluid remaining will be absorbed in a week or two. Owing to the plastic thickening of the upper part of the pleura, considerable dullness still remains, but by forcible percussion I find some resonance, and by auscultation a modified respiratory murmur as low down as the sixth rib behind. If we find after a week or two that the fluid is reaccumulating, we will withdraw it again. This will not have to be done more than once or twice at the outside.

Bibliographical.—In reviewing the subjects of the foregoing lectures, the author would express his indebtedness to the works of Biermer, Burt, Chew, Davis, Donaldson, Fagge, Flint, Fraentzel, Gebhart, Hertz, Hirt, Laennec, Leyden, Loomis, Niemeyer, Nothnagel, Pepper, Salter, Traube, von Ziemssen, Waldenburg, Waters, Weber, and Zimmermann.

LAPARO-COLOTOMY FOR STRICTURE OF THE RECTUM.*

By CHARLES K. BRIDDON, M. D.,
SURGEON TO THE PRESBYTERIAN HOSPITAL, NEW YORK.

Opening the colon for obstruction occurring in the lower bowel, though proposed a century and a half ago, has only been done on a large scale during the last thirty or forty years, and it is not improbable that even now it would be resorted to much more frequently if it were not that many surgeons are deterred from doing it on account of the great mortality as presented in the comprehensive statistics of Batt, Erckelen, and others. Of course, it ought to be taken into account that such records include numerous cases in which the operation was done before abdominal surgery had attained to its present position, and many other cases too far advanced to be aided by intervention of any kind. I think I am not singular in the opinion that no such results follow operations done at the present time.

I believe it is recognized by all practical surgeons that to derive the full benefit from such interference the operation must be done early, not as a last resort to stave off a present or impending obstruction, but as a curative measure; it is now no longer a debatable question whether an early colotomy retards the growth of cancer or the no less clinically malignant cases of spreading, intractable ulcerations that have so long been attributed to syphilis, but which are in no wise influenced by treatment directed against that dyscrasia. I think it is conceded that the operation does exercise such

* Read before the New York Surgical Society, May 14, 1890.

influence, that it is of incalculable advantage in putting the parts at rest and relieving the unceasing misery of tormina and tenesmus that nothing can assuage; but to obtain the full measure of such results it must be done when the first symptoms of obstruction manifest themselves. I regard the danger to life when the operation is done thus early as almost nil, and know of no surgical procedure that affords such marked relief. Some have objected that it is not a radical measure; that it is only palliative and does not cure. To those I would refer the cases that I have reported where patients were snatched from inevitable death by obstruction from inoperable cancer, and to one case where the patient survived an operation done under such circumstances for a period of two years; to other cases where patients worn out by years of suffering from ulceration and contraction were restored, and are now living in the enjoyment of apparently perfect health.

I should not like it to be considered that I object to the extirpation of the disease. I believe that it should always be done, providing we can get beyond the limits of the disease, even if it be necessary to perform the operation of Kraske to insure the removal of the whole; but I believe that an artificial opening in the loin or groin should be a preliminary step; that colotomy should precede proctectomy.

In the *Medical Record*, December 28, 1878, I published a short series of cases of lumbar colotomy, and I was so well satisfied with the results of those operations that I continued to practice it until two or three years ago, when I witnessed some anterior operations done by my colleague, Dr. Lange, and I was so impressed with the advantages of the method, which I understood him to say originated with Verneuil, that I have since restricted myself to that operation, and the six cases reported in this paper occurred in less than a year's practice in the Presbyterian Hospital of this city.

The objects and modifications in the operation about to be described are to prevent the passage of fæces from the upper to the lower opening of the gut, and troublesome prolapse, both of which annoyances have followed the ordinary operation. Madelung's operation was devised to prevent the contents of the alimentary canal passing from above to the bowel below. He cuts the bowel entirely across, stitches the upper end of the divided intestine to the skin, thus establishing an artificial anus; he then invaginates and sutures the cut end of the lower segment, dropping it into the abdominal cavity. The objection to this is that the gut below frequently becomes filled with its own secretion, and if the original obstruction is a tight one, the patient will suffer at times from colicky pains, which would be mitigated if that portion of the canal communicated with the opening in the abdominal wall. Then, again, in the after-treatment of such cases it may be, and I think always is, judicious to disinfect the seat of disease from below or above, and I have been well pleased with the use of a half- or one-per-cent. solution of creolin for such purposes, continued daily for a long time. I am inclined to think that in many cases of cancer, irrigation with disinfectants not only adds to the comfort, but prolongs the life of the patient, and I think they are equally beneficial in the badly ulcerated syphilitic cases.

With the same object in view, Herbert Allingham makes an incision two inches in length and an inch inside the anterior superior spine of the ilium, and parallel with Poupart's ligament; the divided peritonæum is then sutured to the skin. The sigmoid flexure is pulled to the surface, a piece with a long mesentery is then fixed upon, and a needle carrying carbolized silk is passed through the mesentery close to the intestine and secured to the abdominal wall on both sides. The bowel, being slung over the silk thread, is then sutured to the opening in the parietal wall, and it is not opened until two or three days after.

To prevent prolapse of the bowel, Harrison Cripps, F. R. C. S., in a very able article on Inguinal *versus* Lumbar Colotomy (*Brit. Med. Jour.*, April 6, 1889), proposes to select a portion of the gut with a meso only long enough to allow it to be brought into easy contact with the abdominal walls. He also makes his incision in the linea semilunaris, the advantage of which, I think, is doubtful.

I do not think it a matter of great importance whether the incision in the abdominal wall is made through the muscular structures or through the aponeuroses along the outer border of the rectus, providing that it be not made too long. I believe that large incisions are not necessary for the free exit of excreta, and that they favor hernial protrusions of the small intestine into a sac formed out of the colon, and projecting it through the opening in the parietes.

I make my incision two inches long, an inch above and parallel with the outer third of Poupart's ligament, through the skin and muscular tissues, and an inch and a quarter to an inch and a half through the serous membrane. Making the incision through muscle and skin larger than that through the peritonæum very much facilitates the introduction of sutures in the later steps of the operation. A finger introduced into the wound, directly down to the iliac bone and then directed inward, immediately comes in contact with the large intestine, which is drawn into the wound and recognized at once by the bands and glandulæ epiploicæ. At this point it will be proper to select a portion of the gut that has a mesentery that will permit its approximation to the abdominal wall without such traction as would endanger the sutures in the event of meteorism or vomiting occurring subsequent to the operation. This is ascertained by pulling on the knuckle that presents and, if the meso is too long, passing it onward, between the forefingers and thumbs from above downward, drawing out the proximal and returning the distal end, until a portion is arrived at where the mesenteric attachment is judged to be sufficient to prevent prolapse.

A noose of disinfected silk is now passed through the meso at its junction with the gut, and sufficient traction is made upon this to bring the two columns of intestine forming the knuckle parallel, and maintaining such relationship permanent, for the length of an inch or an inch and a quarter, by the introduction of a single or double row of Lembert sutures on either side of the mesentery. In the application of these sutures it is wise to avoid the very numerous small vessels that bleed freely when punctured.

The next step is to suture the parietal to the visceral

peritonæum, and it is well to use two thirds of the opening for the proximal and one third for the distal opening of the gut. This line of suture will be oblique, leading from the point where the mesentery is transfixed by the temporary ligature around the side and crossing the gut about an inch on either side of the point where the contemplated section is to be made. The introduction of these sutures will be facilitated by using small tenacula to lift the peritonæum and hold it in relation with the gut while the sutures are introduced with Hagedorn's fine curved intestine needle.

The gut must now be divided transversely; the section must involve the whole lumen of the canal, except a very narrow strip at the point of attachment of the mesentery. When this is done, the parts are well irrigated, the temporary ligature is removed, and the margins of the incision are united to the skin.

Even with all these precautions, the two ends of the bowel terminating on the surface and attached to each other in parallel lines below the surface, it does happen, in some way inexplicable to me, that a portion of the contents from above will pass into the gut below for a few weeks, but after that time I think it may be predicted that everything will come through the artificial opening.

The operation described above is only applicable to cases where the obstruction is not complete. Its performance requires the introduction of twenty or thirty Lembert and several superficial sutures. They are not easily applied, and the operation is a long one. Indeed, I have very strong doubts whether it is not best to do the operation in the loin in those cases where the obstruction is complete and has lasted several days. In such cases there is frequently very great abdominal distention, and, if an anterior operation were selected, it might be difficult to prevent infection of the peritonæum. There is the advantage of doing the lumbar operation when the colon is distended that it is easily performed, and that the peritoneal investment is out of the way.

In the only two cases in which I have operated for complete obstruction due to stricture of the rectum the advantages of the loin operation were manifest. The first, occurring in the practice of Dr. Hunt, of Cornish Flats, and reported by him in the *Medical Record*, 1878, was for obstruction lasting twelve days, due to inoperable cancer. The lumbar operation was done, the relief was prompt, and the patient lived and was quite comfortable for two years after.

The other case was the last reported in the present series, also for cancer, out of the reach of the knife by any other operation than the one recommended by Kraske. Complete obstruction had lasted two weeks, the abdomen was enormously distended, and the patient's condition was very bad. The indications were for a rapid operation. The anterior operation was done, no attempt at the formation of a spur was made, the intestine was approximated to the abdominal wall by a few sutures, and an incision gave exit to a very large amount of fluid fæces. The patient died in a few hours from shock, and the autopsy revealed no traces of peritoneal infection.

Case I (*Reported by Dr. David M. Marvin*). *Carcinoma of the Rectum; Laparo-colotomy; Recovery.*—Thomas C., aged forty-nine, single, native of Ireland, occupation laborer, admitted to service of Dr. Briddon, Presbyterian Hospital, October 10, 1888.

Family history negative; has had rheumatism; has been intemperate, and uses alcohol freely; denies any syphilitic taint. For five months previous to admission, complained of diarrhœa, tenesmus, and pain in the rectum; stools small, containing mucus and blood; no abdominal pain or stomach disturbance; has frequent micturition, and has lost flesh and strength. On admission, is emaciated and anæmic; skin dusky, almost icteric; liver diminished in size; organs are otherwise negative. Rectal examination reveals a tumor of the size of a hen's egg involving the anterior wall of the rectum, two inches above external sphincter; also an annular growth at same level extending higher than the finger can reach; the new growth is indurated and tender on pressure, and extends into lumen of gut, though the finger passes through it readily.

October 24, 1888.—Patient submitted to operation of colotomy; no pain or elevation of temperature followed. Bowels moved from both the natural and artificial outlet on the day following the operation. Rectum washed out daily with one-per-cent. solution of creolin; sutures removed at the end of the first week; primary union.

During December patient experienced much difficulty in urinating; stream was retarded and attended with pain and tenesmus; fæcal matter passes through both openings.

In January patient decidedly improved; the trouble in urinating had ceased, and all the fæces passed through the artificial opening; blood and mucus occasionally discharged from the anus; odor controlled by the enemata of creolin.

March 19th.—He left the hospital very much improved physically.

Case II (*Reported by Dr. David M. Marvin*). *Carcinoma of the Rectum; Laparo-colotomy; Recovery.*—Carl K., aged fifty-three years, born in Germany, cigar maker, married, entered Presbyterian Hospital, service of Dr. Briddon, January 8, 1889.

Family history negative; uses alcohol moderately; denies syphilis; has suffered during the past year from what has been supposed to be piles; has complained a good deal of pain of a very severe and continuous character; stools mucoid and bloody. Has been steadily losing flesh and strength; patient is anæmic, cachectic, and much emaciated. Rectal examination reveals an ulcerated annular growth two inches above the anus, indurated, and fixed immovable to adjacent organs; it extends beyond the reach of the finger.

January 31, 1889.—Patient was submitted to the operation of colotomy. Recovery from operation uneventful; bowels acted daily, everything passing through the artificial opening; he was shortly afterward removed from the hospital, and eventually died in his own home.

Case III (*Reported by Dr. David M. Marvin*). *Syphilitic Stricture of the Rectum; Laparo-colotomy; Recovery.*—Mary F., aged thirty-one, native of United States, married, housewife, entered Presbyterian Hospital, service of Dr. Briddon, January 14, 1889. Patient gives no alcoholic, tubercular, or rheumatic history, but a decided one of syphilis.

About nine years ago she commenced to use purgatives for gradually increasing constipation, and they became less and less efficient. Three years ago and twice since was operated on for stricture of the rectum, but each time with only temporary relief. She suffers severely from ever-present pain, tenesmus, and constipation, and has a constant purulent discharge from the anus. The lower four inches of the rectum is occupied by a continuous ulcerated surface—irregular, somewhat funnel-shaped, and the examining finger can not pass beyond it.

In view of the fact that long-continued intelligent treatment, including incision of the stricture, and on a subsequent occasion proctotomy, had done no good, the patient was advised to submit to an operation for artificial anus, and that operation was done on January 19, 1889. The recovery after the operation was uneventful; bowels moved daily after the third day; temperature ranged from 99° to 100° F. till the bowels moved, when it fell to normal and remained there. The lower bowel was washed out daily with a one-per-cent. solution of creolin. On February 5th the patient left the hospital in apparently perfect health, and suffering very little if any inconvenience from the artificial anus.

Case IV (*Reported by Dr. David M. Marvin*). *Syphilitic Stricture of the Rectum; Laparo-colotomy; Recovery.*—Mary M., aged thirty-three, married, born in United States, housewife, was admitted to service of Dr. Briddon, Presbyterian Hospital, on March 4, 1889.

The patient gives no alcoholic history. Six years ago she had an acute articular rheumatism. At the age of fifteen years she contracted syphilis from her husband. For the past ten years constipation has been her chief trouble, defecation being attended with great difficulty and pain, added to which she has a constant wearing pain in the left iliac fossa. Latterly she has ceased to have control over her bowels, and has a discharge from the anus muco-purulent in character.

On admission, she was found poorly nourished and anæmic. Temperature 100° F., pulse slightly accelerated, urine negative. There are some cutaneous tabs aronnd the anus. A very tight stricture, which will admit only the little finger with difficulty; its upper limit can not be felt. *Per vaginam* the greatly thickened walls of the rectum can be felt, reaching up to the limit of the posterior fornix. The uterus and, in fact, all the pelvic organs are found matted together. In the upper part of the posterior vaginal wall is a fistula communicating with the rectum and permitting the passage of fæces.

On March 9, 1889, submitted to the operation of colotomy. Her bowels acted on the fourth day. Primary union obtained. Everything passed through the artificial outlet. The lower bowel was irrigated with creolin daily, her recto-vaginal fistula ceased giving her any trouble, she gained remakably in health and strength, and left the hospital cured on March 22d.

Case V (*Reported by Dr. Henry L. Shively*). *Stricture of the Rectum; Laparo-colotomy; Recovery. Service of Dr. Briddon.*—Maggie L., aged thirty-one, United States, married, housewife. Her father died of Bright's disease; otherwise there is no morbid family history. She had one child twelve years ago; following her labor she developed puerperal fever, and was confined to her bed for a period of three months. Seven years ago she underwent an operation for fistula in ano, and, three years later, a second operation for ischio-rectal abscess. The first symptoms of her present trouble developed a few weeks before the appearance of this abscess. She suffered from obstinate constipation, and there had been a progressive loss of flesh and strength. At times she suffers severely from shooting pains in the rectum, and obscure abdominal pain. Menstruation has always been regular.

On admission, the patient is very poorly nourished and anæmic. Urine contains a trace of albumin, granular and hyaline casts. On digital exploration of the rectum, there is detected a firm annular stricture, which, just admitting the index finger, extends upward and beyond reach; the walls are very much infiltrated, and the whole surface is ulcerated. The futility of palliative treatment having been demonstrated by the long-continued ineffectual use of bougies, the patient seeks relief by the operation of colotomy, which was done on October 11, 1889. The history afterward was uneventful; she had no elevation of temperature, had a few movements from the natural outlet, and then everything passed through the artificial opening. The relief was marked and prompt. She at once began to pick up health and strength, and was discharged cured on November 13th.

Case VI (*Reported by Dr. Frank Le Moyne Hupp*). *Laparo-colotomy for Complete Obstruction of Fourteen Days' Standing, due to Cancer of the Rectum; Death in a Few Hours from Shock; History.*—Samuel I., aged fifty-five, baker, family history of no interest; no rheumatic, malarial, nephritic, or syphilitic history; there is a mild alcoholic habit. Admitted to the medical wards of the Presbyterian Hospital on December 2, 1889, giving the following history: Two weeks previous to admission he was seized with general abdominal pain; its onset was sudden, and its character was sharp and shooting. Except one small unsatisfactory motion, the bowels have been obstinately closed since the first appearance of the pain. He has also been greatly troubled with vomiting.

On admission—temperature, 99·5°; pulse, 120; patient is fairly nourished, but anæmic; face is pale, and expression betokens anxiety. Tongue is coated. Abdomen markedly tense and enlarged, tender on palpation. In the right inguinal region there is more decided resistance to the touch; an elongated mass is felt, dull on percussion. In the middle and upper part of the abdomen a tympanitic note is obtainable; in the left inguinal region there is dullness, but the bulging is less marked than on the right side. Says that more than a year ago he experienced a similar but much less severe attack.

A rectal examination reveals an annular constriction about a finger's length above the external sphincter; it apparently occludes the lumen of the gut; there are several pedunculated growths growing upon its under surface.

December 5th.—Patient is transferred to the surgical division, service of Dr. Briddon, and immediately prepared for operation at 3 P. M. Ether narcosis: an incision was made an inch above and parallel with the outer third of Poupart's ligament, two inches in length; incision in peritonæum, an inch and a half; patient's condition was critical; no attempt was made at the formation of a spur; the colon immediately came into view, as recognized by longitudinal bands and appendices epiploicæ. It was drawn out, attached to the opening in the abdominal wall by a few sutures, and an opening was at once made, giving exit to a large quantity of fluid fæces and a considerable quantity of gas; when this ceased, the cut edge of the colon was secured to the skin, when a second and more profuse discharge began, and continued for some time. This was followed by a marked diminution in the abdominal distension; but the patient never rallied from the shock, and died about twelve hours after the operation.

In Case I it will be noticed that the contents of the alimentary canal continued to discharge through the natural anus for several weeks; this was due to the incision in the intestine in that case being made in the longitudinal instead of the transverse direction. It will also be noted in the histories of the cancer cases that they are reported as having been discharged cured; it will be understood, of course, that the term applies only to the conditions complicating the disease, and not to the disease itself.

In conclusion, I would beg to submit the following propositions:

1. By abolishing function in that part of the bowel below an artificial anus, and instituting another route of ingress for treatment, we retard those progressive destructive processes in cancer and in the quasi-syphilitic ulcerations,

and eliminate the principal causes of suffering associated with those diseases.

2. To prevent the annoyance caused by fæces passing from the part above to the part below an artificial anus, we must resort either to the objectionable method of Madelung, or to some of the various methods for the formation of an *éperon* or spur.

3. To prevent the annoyance of subsequent prolapse, we must make the section in the abdominal wall as small as consistent with the object in view, preferably through muscular tissue, following in other respects the advice of Cripps, selecting a portion of the colon that has a meso only long enough to reach the surface.

4. A great deal can be done in the treatment of non-cancerous stricture by the faithful, gentle, and long-continued use of bougies, and other local and constitutional means; but to derive the full measure of relief from iliac colotomy, it must be done early and before the occurrence of complete obstruction. When that has taken place, and we have to deal with a largely dilated abdomen, I believe that the lumbar operation is the preferable one.

REASONS FOR THE RELATIVE IMMUNITY FROM PULMONARY PHTHISIS IN COLORADO, AND ITS THERAPEUTIC IMPORTANCE.

By H. B. MOORE, M. D.,
COLORADO SPRINGS.

The word relative might almost be omitted from the above wording, for the number of cases of tuberculosis originating in Colorado are proportionally so small as compared with what obtains in other parts of the world that immunity from tuberculosis in Colorado stands practically as a fact. An immunity exists also in some parts of the South American Andes, in certain restricted areas in the Alps, and also in other portions of the world, the climatology of which has as yet been little studied. When we ask ourselves for the reasons for this immunity and look up what has been written on the subject, we are confronted with much speculation and uncertainty. In fact, not a small portion of the profession still holds to the belief that if such areas of immunity exist at all, it is only by virtue of an absence of the conditions usually present in thickly settled communities, or, in other words, that it is simply a negative, not a positive, attribute of said areas. With a view to settling this point, the Swiss commission was appointed in the year 1865 to ascertain and report upon the sanitary conditions and percentage of deaths from tuberculosis at different altitudes in Switzerland. The statistics accumulated by the commission covered a period of four years, and Müller in his published report states that, although no areas of absolute immunity were found, it was ascertained that, sanitary conditions remaining the same, a relative immunity existed at various altitudes, modified by latitude and local conditions. Independent observers in various localities have also given more or less conclusive testimony on this point —*e. g.*, Küchenmeister's collection of statistics for Saxony, Jacubasch's for the Hartz Mountain region, and those of Bremer for Görbersdorf—and the fact is further evidenced by the degree of immunity observed in the highly situated Andean cities and those of the Central American and Mexican plateaus.

Prior to the discovery of the tubercle bacillus by Koch in 1882, those who sought to explain local immunity were at a disadvantage, inasmuch as the intimate, essential nature of the disease was still unknown. Since that time, although bacteriology is doubtless still in its infancy, much has been learned of the grosser laws governing bacterial life and its propagation. We know, *e. g.*, that certain degrees of heat and moisture and certain media present conditions much more favorable than others to these low forms of life. We also know that these limits vary widely in different bacteria. It is from a study of these general laws and of the special facts relating to the culture of the tubercle bacillus that we are to draw data, whose comparison with the conditions found in a given climatic zone will aid, at least negatively, in the solution of the question. Without going into details exhaustively, the main facts concerning the conditions essential to the life and propagation of the tubercle bacillus, as determined by experiments in artificial media, are briefly as follows: The bacillus itself is extremely fastidious as to its culture medium and extraordinarily sensitive to changes of environment. In ordinary culture media—gelatin, agar-agar, and bouillon—it grows either not at all or very incompletely, and it is only in blood serum that it thrives. This sensitiveness is further exhibited to a marked extent against changes of temperature and dryness. Above 108° and below 86° F. development ceases entirely and is only complete at the temperature of the body.

This fact is so rigid that in its cultivation an oven kept at a uniform temperature is a necessity, and added to this is the third fact, that, owing to its very slow growth, there must be an undisturbed continuance of these conditions for a relatively long period. In the face of this, it might be a matter for wonder that the tubercle bacillus existed at all were it not that its spores are as exceptionally resistent and unyielding to adverse influences as the bacillus itself is the reverse. This spore formation goes on both in the body and outside in the sputum, and the resulting spores are among the most resistent known. They will stand dryness for months, temperatures of boiling point for hours, and long exposure to low temperatures as well. From a consideration of the foregoing, we can readily see that if bacilli were all we had to contend with, many climates could offer strong anti-tubercular properties. The disease might even soon cease to exist; but, unfortunately, tubercular spores have such powers of resistance that probably no habitable climate could enjoy immunity by virtue of any specific antiseptic properties possessed by it. It is, however, doubtless true that spore formation and the consequent multiplication of bacilli are much inhibited by the conditions peculiar to mountain regions. Miquel ascertained that in a given quantity of air taken as a standard for comparison there were absolutely no bacteria over the Mer de Glace at Chamounix, Switzerland; that in the same bulk of air in a hotel corridor at Lucerne were twenty-five and in Paris seven thousand. Of course the overwhelming majority of these or-

ganisms were non-pathogenic, and these facts admit of but limited application to the subject under consideration. The presence, then, of any specific germicidal effects in high altitudes not being admitted, we must look for the reasons for immunity in some change in the individual whereby he loses his susceptibility, or, in other words, no longer presents a ground adapted to the reception or growth of tubercular seed, or, as the bacteriologist would put it, he ceases to be a suitable culture medium. These changes in individuals living in the immune areas of Colorado are due to the following essential climatic peculiarities, whose effects and therapeutic significance will be briefly considered in the order named: Atmospheric attenuation, dryness, purity, increased opportunity for out-of-door life, and sandy, porous soil.

Among the most conspicuous effects of high altitudes is the increased expansive power of the lungs. This fact is so generally known and recognized that it needs no comment. It signifies, of course, that, owing to the atmospheric attenuation, to fully meet the needs of the system greater respiratory activity is necessary, and that portions of the lungs but little used at sea-level are brought into requisition, and the whole organ takes on increased functional activity with all the incidental nutritive advantages, according to the known law that tubercle has a special affinity for organs that functionate incompletely, and its converse, that their power of resistance and vitality exhibit a direct ratio to their functional activity.

The effects upon the heart and its nutrition are also conspicuous. At first the pulsations are considerably increased in frequency, but this disappears after a time, as the heart becomes gradually larger and the performance of its work more vigorous. In this connection the observations of Rokitansky are of much interest. He declared that the heart and vessels were always relatively small in chronic phthisis. I have often heard Formad, coroner's physician in Philadelphia, say that he had observed the same thing in large numbers of autopsies, and Bremer, of the Görbersdorf Heilanstalt, said that it held true of the 14,000 cases treated at his institution during its history. Bremer was a pronounced believer in the theory that this relative smallness was a prominent ætiological factor in the production of phthisis, and that the benefit of the high-altitude treatment was to no inconsiderable extent due to the effect upon the heart and closely related pulmonary nutrition. Although this may seem rather hypothetical from our present standpoint and mode of thought, yet it is better not to blind ourselves to its *possible* overtowering importance in predisposition, especially when we reflect upon how slight is our knowledge as to the essential nature of predisposition. It is at any rate obvious that any change of environment having for its consequences such marked effect upon respiration and circulation must be powerful for good or evil.

As a further effect of high altitudes is to be mentioned the marked improvement in appetite and assimilation. This seems to occur independently of any qualities in mountain climates other than atmospheric attenuation and the cold, bracing air, and probably by the power these qualities possess of imparting to all of the organs a more perfect functional life, combined with a tonic effect upon the nervous system, thus overcoming "vulnerability" of tissue. The rôle played by extreme dryness can, it seems, hardly be exaggerated, and in its direct effect upon the local process is probably nearly equal in importance to elevation. Dr. Denison, of Denver, who has given this subject special study, has made some interesting observations on the increased osmosis of watery vapors at points on the eastern slope of the Rocky Mountains taken as a type of dry climates and places upon the Atlantic seaboard. He also says that "if we knew to-day the absolute humidity of, or the average amount of vapor in, a cubic foot of air in all parts of the country, we should have one of the most valuable indications possible of the best localities for phthisical patients. With some reservation as to temperature, the smallest ratios would indicate where consumption seldom originates." The infrequency of phthisis in the dry parts of Egypt, Australia, Arizona, and other places furnishes good evidence of the correctness of this view, at least as an adjunct to altitude; and in cases in which, for any reason, high altitude is contra-indicated, and the patient can not be allowed to enjoy a combination of the two, a low altitude with dryness should be chosen.

An absolutely dry air, possessing, as it does, great absorbent power, is actively opposedto suppuration, being, as it were, a constantly applied aseptic blotting-pad to suppurating surfaces, and quickly drying up those patches of broncho-pulmonary catarrh so frequently the nidi for tubercular infection. The drying, shriveling process which beef or carcasses exposed to the air in exceedingly dry countries undergoes will be a familiar and remembered example by those who have observed it. Apropos to this subject, I wish to make a few remarks on equability of temperature and wind.

Exceedingly dry countries, like Colorado, show an entire absence of that equability which is the concomitant of and can only be secured by the latent equalizing influence of large surrounding bodies of water and moist atmospheres, of which Florida is an example; hence those writers who speak of "dry equable climates" affirm what is paradoxical and, from the teachings of physical science, impossible. As for wind, a study of the mechanism of its production will show that it also is a necessary feature of dry climates, and if it is not found in a special area, it can only be a local accident—the result of a sheltering range of hills or spur of mountains. Dryness has the further advantage of robbing oscillations of temperature of the danger and discomfort otherwise attending them. The special *purity* of mountain air is well shown by the results of Miquel's observations above alluded to, which have obtained such wide-spread currency, and, excepting warmth, purity is the most classic desideratum in the selection of climate for phthisis. Dr. Anderson, of Colorado Springs, believes that the beneficial effect of the Colorado climate is due almost entirely to the purity of the air and its aseptic condition. This is also the view of many of the most eminent clinicians of Europe and this country, and its importance is emphasized by the preponderating influence in the production of phthisis of crowding and poor ventilation. Now, while I have no intention of being heretical upon such an essentially orthodox point as the necessity

for pure air in general, yet I think its importance has occupied the professional mind for a long time to the exclusion of what are in this connection more unique climatic attributes. Otherwise how can we account for the degree of immunity which still exists in many large, growing cities at high altitude, of which Denver may be regarded as an example. The sanitary conditions in these cities are certainly not above the average for cities of their size; in many cases conspicuously worse, as evidenced by the prevalence of typhoid fever and other diseases associated with such conditions. In view of this high appreciation for pure air, it is curious to note the proposal in Germany not long ago to treat pulmonary tuberculosis by spray inhalations of highly fœtid, stagnant water, containing the *Bacterium termo* in large quantities—the theory being that these bacteria would antagonize and eventually destroy the bacilli of tuberculosis in the lungs in a manner similar to what occurs in impure artificial culture media. Many who gave this seemingly unpromising method a trial professed benefit, but most met with negative results.

Our next point, the largely increased opportunity for out-of-door life furnished by the climate of Colorado, becomes obvious when one learns of the unprecedentedly large number of sunshiny days during the year and the average monthly temperature throughout the same, rendering out-of-door life not only possible, but a pleasure during every month. In this respect the advantage of Colorado over the Engadine and similar high-altitude resorts abroad is most conspicuous. Of the happy influence exerted by out-of-door life, particularly in early cases, no one has a doubt. It has been the universal experience everywhere in localities of no special promise. The last point to be mentioned is the character of the soil, which, along the eastern slope of the mountains in Colorado, is sandy and porous. Dr. Solly states that in the neighborhood of Colorado Springs this sandy, porous soil obtains to the depth of sixty feet. Dr. Bowditch, of Boston, and others since have accumulated a mass of evidence to show that phthisis is much more frequent in localities having a heavy, moist, or clayey soil, and, although some have attempted to show that the opposite character of soil has some special positive virtue, it seems more rational to attribute the salutary influence of sandy, porous soils to their influence on dryness of air and drainage. We owe the immunity in Colorado, then, chiefly to the physiological effects of high altitude. This is powerfully supplemented by extreme dryness, while the almost unbroken sunshine and favorable temperatures lead to a maximum amount of out-of-door life, rendering the specific action of altitude thoroughly available. Probably no one of these climatic attributes would be sufficient in itself, but the sum of these conditions effect such a change in the human economy, viewed in the light of a medium for tubercular cultivation, that it becomes unfitted to the end; and in cases of the disease not too far advanced, this influence antagonistic to the tubercular process is so strong that it becomes antidotal and a most valuable therapeutic agent.

To fully appreciate the fairness of this conclusion, a correct conception of the natural history of phthisis is most essential. It has been variously estimated by different observers that the lesions denoting a pre-existing phthisis are found in from thirty to sixty per cent. of all autopsies. Very many of these people have had phthisis and recovered without knowing it. Flint has shown that in a large number of cases of phthisis there is an intrinsic tendency to recovery irrespective of any special treatment or management. In these cases the system exhibits a marked tolerance for the disease, and it occasions but little disturbance.

In all ordinary cases of phthisis pursuing a chronic course, Nature makes strong and repeated efforts at self-cure, the tubercular mass frequently becoming encysted and shrinking into a hard, atrophied, innocuous mass. When these efforts are not successful, the repeated attempts at fencing in and curing are not less evident, both clinically and post mortem. Thus we see that phthisis is not a disease that is necessarily fatal, and it appears that these climatic influences which we are considering are just sufficient to turn the balance in assisting Nature on the local process, and to put the stamp of success on what she herself so earnestly attempts. I know of no words that better express what may be expected in properly selected cases coming to Colorado than these by Dr. Knight, of Boston: "It is perhaps not too much to say that the prognosis in this class of cases (early apex disease) has been changed from very bad to very good."

ADENOID TISSUE IN THE NASO-PHARYNX AND PHARYNX.

*PRELIMINARY REPORT.**

By H. L. SWAIN, M. D.,
NEW HAVEN, CONN.

Several years ago, while studying the development and history of the lingual tonsil, many observations were made upon this variety of tissue as it presents itself in other portions of the pharynx, and it was the writer's purpose, at some future date, to continue the study of these latter portions of adenoid tissue, tracing the life history of the whole mass. To a few observations thus made in obedience to the above purpose the writer would ask your lenient attention, hoping more to elicit thereby a discussion that shall prove profitable, rather than with any idea of adding anything of value to the knowledge already at hand in extant literature.

Since beginning the work in this direction much has been written on this tissue, and a great many points which interested the writer at the start have been definitely settled, but at the same time the field has broadened, and so, instead of busying ourselves with minute details, let us consider as a whole this ring of tissue which we are pleased to call adenoid, situated at the junction of the œsophagus at its dilated upper extremity and the mucous membrane of the mouth and nose. In so doing, however, we may not slight its principal component parts, but must consider them in their relations to each other and to the whole, and their joint or comparative life history.

---

* Read before the American Laryngological Association at its twelfth annual congress.

Situated as is this ring of tissue, acting as a sort of bridge or other bond of connection between structures which are, on the one hand, originally developed from the entoderm of the embryo, and, on the other, with parts largely affected by ectodermoidal influences, it differs from the tissue in its immediate neighborhood quite considerably. It also has slight variations in the structure of its different parts—a difference in their life history—for some parts atrophy early, while others seem as active as ever even up to the middle of life, and yet all these differences are to be more than outnumbered by the variety of opinions as to the purpose of the adenoid tissue and its function in our economy.

To state in general what we know of the life history of these interesting parts, we might put it as follows: That way back, early in the uterine existence of man, the deposit of small cells underneath what then is the epithelium of the naso-pharynx and pharynx begins, accompanied or at times preceded by a slight furrowing of the membrane; very soon after this beginning comes the outwandering of the same cells through the epithelium. At some time later, the date varying in different portions as does that of the beginning, thickening takes place, and soon development of follicles. After a time, when extra-uterine life has begun, all parts grow on apparently alike until puberty, or toward adult life. Then activity seems to subside and a gradual retraction takes place. In general, we find already in late youth a beginning of atrophy in the pharynx tonsil, later on the faucial tonsil begins its retrogression, while way into adult life we find the lingual tonsil still unatrophied.

The apparent corollary of the foregoing is borne out in clinical experience, for we have in young children the adenoid tissue in the naso-pharynx and faucial region more often affected by disease. In youth and early adult life the faucial tissue attracts our attention, while in a large majority of the cases which demand treatment the lingual tonsil seldom appears to be affected before the twenty-fifth year. Of course we have many exceptions, as acute affections of the pharynx tonsil in the adult, or enlargements of the lingual tonsil in the child. There is also, in general, the same order of development—that is, the pharynx tonsil begins certainly as early or earlier than the faucial, while both precede the full development of the lingual tonsil by quite a long period. In all, the formation of follicles follows at some considerable time interval after the deposit of small cells takes place, and in the case of the lingual tonsil it seems quite certain that pathological conditions favor the earlier development of the follicles, and that the more hypertrophied a portion becomes, the more follicles it contains. It proves to be also true that in the atrophy of the lingual tonsil the follicles first break down and disappear, and then a general diminution in the number of cells in the infiltrating mass under epithelium. This would seem to be also true of the other portions of this tissue in the pharynx, but, from individual investigation, the writer can not say, for this is one of the points aimed at in investigating this subject, and it is proposed to examine all portions of this tissue at the different periods in life, making comparative observations on the condition of the different parts.

In studying the development of the pharynx tonsil we have a great authority in Killian (5),* and the observations made by the writer entirely coincide with his, so I shall venture to quote him quite at length. He examined in all some sixty-five human embryos, and found that, while the real bursa pharyngea, according to Froriep, came as early as about the eleventh week, the first folds in the mucous membrane at the vault of the pharynx appeared at the beginning of the sixth month. These folds preceded any appearance of small cells, which begins usually toward the last of the sixth month. During the seventh and eighth months the folds assume a size sufficient to be discovered by the naked eye. Soon they assume the irregular details familiar from observation in the adult, the folds being often upright with occasional transverse. There is every variety of form and extent in the case of these changes, and the time of their appearance is far from regular, or the tonsil may be wanting entirely at birth. The real adenoid tissue is formed by the mucous membrane taking up numerous round cells, until it becomes quite full and, by a rapid proliferation of these cells, grows considerably thicker. In the beginning the whole process confines itself to the posterior three quarters of the roof of the pharynx; later it spreads down on to the posterior wall of the pharynx. It is always thickest in the front region of the bursa—*i. e.*, just in front of the angle or curve formed by the roof with the posterior wall of the pharynx. Toward the end of the embryonal life these folds become thick protuberances and form deep furrows, of which the middle one appears to be the greater. At about this same time the follicles (Schmidt) (10) appear, although in certain cases they may not be found for some time after birth. These glands have no hollow spot, as in the case of the other collections of conglobate glands. Mucous glands are more abundant in the superior-lateral regions of the naso-pharynx.

After birth there is an apparent change of position of the pharynx tonsil which he states as follows: "The pharynx tonsil of man moves, between the sixth month of embryonic life and end of the second decennium, from the baso-sphenoidal to the baso-occipital region."

From his studies in comparative anatomy he concludes that in mammals the pharynx tonsil is not so constant as the faucial tonsil in its occurrence, but at least is as frequent as the lingual. In the lower forms of life, as in birds and reptiles, it is present in a well-developed form, and therefore, of all these collections of lymphatic tissue in the throat, is the oldest. Perhaps right here is a favorable opportunity of stating some observations by Beard (1), reported in an article entitled The Old Mouth and the New. In this he seems to present logical reasons for supposing that the old mouth—viz., the mouth which the lowest grades of animals, as the worm, possess, a direct continuation of the œsophagus to the surface—was by means of the hypophysis cerebri through the present infundibulum to the upper and back part of the head. Such having been the case, we have abundant reason for the fact of the frequent occurrence of the pharynx tonsil in the lower grades of animals,

* Numbers refer to literature.

and in this latter the reason for the earlier development and activity of these tissues in man.

One other point of importance and I am done with the embryology of this part: "We must conclude that all three tonsils and the whole adenoid tissue at the beginning of the embryonic intestine are formed by the participation of the entoderm as motive principle, and the mesoderm as the source of the adenoid infiltration. These parts must be looked upon as morphologically similar to the lymphatic organs of the whole intestinal canal."

We find in these statements of Killian much which is not in strict accordance with the hitherto accepted views, but I can heartily agree with him when he states that the real bursa pharyngea, pure and simple, as described by Toruwaldt and Luschka, has only a somewhat inconstant embryonal existence, and does not persist as such in the adult, or even long into childhood. It is not the dilated end of the hypophysis cerebri, or rather the canal from it to the pharynx. The true bursa exists before the tonsil proper begins, and is not to be confounded with the recessus pharyngeus medius of the adult, differing thus entirely from Schwabach (12) and Ganghofner (4). Poelchen (8) is perhaps the latest writer on this subject. He avoids all questions as to the bursa or recessus, but insists that the median groove exists all through life, and must necessarily do so, because this portion is attached so firmly to the base of the skull, between the insertions of the longus capitis muscles. In a patient where the side of the face had for surgical reasons been almost entirely removed, thus giving a clear view directly into the naso-pharynx, it was the only portion of the pharynx which did not participate in the motions of the act of swallowing, the pharynx walls always coming together from side to side.

Having thus considered the upper portion of the ring of adenoid tissue, as we come down on either side we have the lesser accumulations, such as the tube tonsils, the lateral column of the pharynx, and then we come to the faucial tonsils. Concerning the first two I have little to say, but a point that I have not yet sufficiently proved seems, however, to be probable from abundant clinical observation—viz., that, while the lateral columns may not possess any actual conglobate glands in any number, still, in common with the lingual tonsil, they preserve a later activity than the other parts, for we frequently find them hypertrophied together in late adult life.

Of faucial tonsils we know definitely that the beginning is as a fine groove, around which the infiltration accumulates, which goes on to the formation of deep sulci and the development of the organ so familiar to us all. In point of time the faucial tonsil seems to begin about the same time or perhaps a little later than the bursa pharyngea of Killian. According to Kölliker, the follicles of the conglobate gland are always nicely developed at birth, and he mentions the same as a fact in connection with the lingual tonsil. As regards the latter, such is, from my own observations, not at all constantly the case, for, as stated in another place, many cases of young children were examined where not a follicle was to be found. The time seems to be quite uncertain, and as regards the first appearance of the infiltration, I have not had a chance to examine very young embryos. Suffice it to say that this same infiltration antedates the appearance of actual follicles by a considerable interval, and at some future time I hope, from human embryos now in my possession, to be able to speak more definitely. In animals the lingual tonsils begin at a decidedly later interval than the others in almost every instance.

Having observed these differences in the time and kind of formation in the various parts of the throat, we find a very beautiful connection with the observed facts in clinical history. The pharynx tonsil, the older organ in the history of animal life, is first affected in childhood by whatever of pathological changes take place in this tissue, and having fulfilled, as it were, its mission, even when not affected pathologically, it later atrophies, and this work is assumed by other parts. What is true of this portion seems later true of the faucial tonsil, while, to finish up with the work, we have, as the more persistent member of the group, the lingual tonsil, and perhaps the lateral pharyngeal columns. A later report will deal with this retrograde metamorphosis.

Evidently this tissue is not present in our bodies in the position which it occupies without fulfilling some definite purpose, and is it not possible to make some inference from this peculiar history of development and atrophy?

Killian states that the only function which these considerable surfaces, through which multitudes of leucocytes are constantly emigrating, seem to possess, is evident in the power which these cells have to destroy micro-organisms. Hence he would argue that the pharynx tonsil, being the first met by the incoming air, would play the greater part in ridding the system of these dangerous elements always present in the air about us. More of these little creatures are to be supposed to be present in the impure air that occurs in close rooms, and consequently there would be a greater demand put upon this organ in the animals subject to these conditions—*i. e.*, man and the house or domestic animals. This increase in demand for leucocytes would lead in the course of generations to a greater development of these tissues, and man and the animals referred to would come to possess larger adenoid collections, a fact borne out by his observations in comparative anatomy, excepting, perhaps, that rodents, save the rabbit, do not appear to be blessed with much of any adenoid tissue.

The converse was equally well borne out by his observations, for in those animals where the nose is long and very complicated, and the air does not come directly in contact with the pharynx tonsil, as in man, no such eminent demand would be made on this tonsil, and so in succeeding generations we would see it disappear as is the case with many mammals. His opinion is somewhat influenced, if we may be allowed the inference, by the interesting account which Metschnikoff (6, 7) gives of the warfare waged by the leucocytes or their analogue in the *Sprosspilzenkrankheit* of the *Daphnidæ*, and against the erysipelas micrococci. He observed unquestionable examples of the antagonism existing in these cases, and so the inference was fair that a like animosity exists against other micro-organisms.

Spicer (13) believes, in common with H. Fox, that the

pharynx tonsil, as also the other adenoid tissue, acts as a preventive against too great a use of fluid, in that, in the pause between each two acts of swallowing, they absorb the fluid of mucous membrane of the mouth, as also certain parts of the food while they are passing by; and finally, as a place of nourishment for the leucocytes, they take part in production of blood.

In common with Schmidt and Stöhr (14), they all agree that the collection of the leucocytes here must have some significance in regard to the blood; in short, adenoid tissue is a sort of blood-producing organ; but Killian rather puts this feature in the background and thinks the function is more in the way of protection against deleterious matter.

Davidoff (3), in speaking of the leucocytes in the intestinal epithelium, puts another interpretation upon their presence in this situation, and, far from supposing them to be fighting micro-organisms, he conceives that they are the carriers of some of the digested food through the epithelium into the intestine. Thus he believes in direct opposition to Stöhr, who first drew attention to the immense immigration into the throat. Stöhr, while he says but little about the fate of the leucocytes after they leave the epithelium, distinctly believes in there being some relationship existing between the demand of the rest of the body for leucocytes and the number present in adenoid tissue, for he mentions an almost complete lack of cell immigration in several cases of persistent formation of pus, pyo-pneumothorax, and a considerable lessening of the normal number in a case of leucæmia.

Whichever of these theories we adopt, we can not escape from certain difficulties in trying to explain certain observed phenomena. For example, if the sole purpose of the adenoid tissue of the throat is to furnish leucocytes, which shall protect us from the invading host of rapacious micro-organisms, then we may safely conclude that for those who breathe through the nose the pharynx tonsil is really the most valuable in this particular. Is it not strange, then, that this should be the first to atrophy, when it is the one most needed? To be sure there are the other parts still left, but they can not get at the inspired air. Or must we suppose that the pharynx tonsil takes care of the air, while the faucial and lingual do duty in fighting the organisms present in the secretions of the mouth and pharynx? This takes place in the youth of the individual, and later in the adult there is not such an urgent necessity for such protection in that other organs may do the work, or the system be more capable of resisting. Certainly if the above be the case, we must not be hasty in removing enlargements of these organs unless we find them to be producing disease of other parts, for one can not have too many leucocytes at his command. And yet while we find these little inconsistencies, surely we must almost *a priori* conclude that the leucocytes must exercise some protective influence, and that an active one, for how could we otherwise so often escape infection? Surely nothing would seem more favorable to the ingress of organisms in the system than the tonsils, which present in the lacunæ the most convenient of resting places for microbes, and then in the openings which unquestionably exist in the epithelium we have an almost open door for the entrance of the little micrococcus. Granted that the majority of the organisms referred to are entirely innocuous, still some are not, and were it not for some active interference, we must often become infected under the conditions just quoted.

The question of retrograde metamorphoses or pathological changes we must leave for the report of future observation, which I hope to make. Meanwhile let me simply mention again the observation of Poelchen, which he cites to explain the very frequent appearance of and persistence of diseased conditions of the secretion high up in the naso-pharynx. The close union of the apex of the recessus medius by fibro-cartilaginous bands to the base of skull between the muscles rectus capitis gives an immobility to the parts that tends to the retention of secretions, and that the more as by the movement of the side walls toward each other it is into this recessus that the secretions are poured as into a conduit. The deduction is to supply what nature does not afford, and especially to be observant of adhesions or thickenings, which may hinder the easy downward flow from the recessus.

PRELIMINARY CAPSULOTOMY IN THE EXTRACTION OF CATARACT.

By T. J. TYNER, M. D.,
AUSTIN, TEXAS.

Owing to the great amount of literature recently devoted to the subject of cataract extraction, I owe it to you as a matter of courtesy, as well as in justice to myself, to say I would not presume to bring it forward now had I not failed after diligent search to find a precedent for the operation which I shall hereafter describe, and which I believe possesses some merit. The nearest approach to it is in opening the capsule with the point of the knife as it enters the anterior chamber while the section is being made and with which you are all familiar.

The leading point in the operation is in making the capsulotomy the primary step, thereby enabling the operator to deliver the lens at the very moment the corneal section is completed. I will not encroach upon your time with the progressive history of the many methods devised by different operators, nor with the details of this operation as to instruments, antiseptics, after-treatment, etc., as they differ in no essential particular from the generally accepted measures in other methods.

Supposing the eye to be now ready. A Bowman stop-needle is thrust into the anterior chamber—the pupil having been previously dilated—the point of which, and also the entire field of the incision, are in full view.

The capsule is now lacerated in its upper quadrant, the line of incision corresponding to the upper pupillary curve of the iris. In this manipulation and in withdrawing the needle, the greatest care should be observed that no aqueous is lost. The eye is now practically undisturbed and as favorable for the corneal section as before, which is to be done quickly, using a Graefe knife, preferably rather broad. When the section is finished, pressure with the flat of the blade causes the corneal opening to gape, when at the same moment counter-pressure with the fixing forceps below aids the expulsion and the lens glides out through the still open pupil with surprising ease.

I will mention here that the lens, having no choice, or rather no other avenue of escape, almost always indicates a tendency to follow the knife as the corneal incision is progressing, and when it is finished the lens is partly in the anterior chamber. I state this to demonstrate why it is so promptly delivered and that the foregoing expression is not extravagant.

The operation is simple throughout and easily done, and is accomplished when the most difficult part in other methods begins. An additional point of interest is: If the lens is susceptible of being dislocated—and this is made manifest so soon as the needle touches the capsule—there is, in my experience, no way to accomplish it so perfectly and harmlessly as with the needle at this stage of the operation. This is somewhat similar to Delgardo's method, and, strange to say, was the result in my first case, which occurred last October. Since then I have performed the operation twelve times with a good result in each one, or, to be more definite, with the exception of two cases, the result was far better than that formerly achieved. In the two cases referred to there was severe iritis with posterior synechia, and in four others it was manifest, but only in a very mild form. In the remaining six cases there was absolutely no reaction. I am inclined to think the iritis was in part due to the excessive strength of the atropine used in dilating the pupil, which, a few hours after the operation, reasserts itself, hence crowding the iris nearer the corneal wound. I now use the weakest solution of atropine that will serve the purpose. Eserine might be useful in some cases, though as yet I have not felt the necessity of resorting to it.

I neglected to mention in the foregoing statement that in three of the cases the lenses were extracted in their capsules.

If you will now bear with me a few moments longer, and I trust not without interest, I will relate the circumstances, which by the way were partly accidental, that led up to the development of the operative procedure above described. In July, 1885, I operated on a Mexican, and while I was opening the capsule, having done an iridectomy, fluid vitreous escaped so rapidly that the globe was so collapsed that the lens could only be delivered by the aid of the iris forceps, having fallen into the posterior chamber. Singular to say, there was a good recovery with useful vision, which result encouraged me a few weeks later to attempt the extraction in the other eye. Anticipating the same condition of vitreous, the thought suggested itself to open the capsule with a needle previous to making the corneal section. This was successfully performed, and, while there was loss of vitreous (fluid), it was slight compared to the first. This case is recorded in the published statistics of Texas surgery in 1886. This little procedure passed out of my mind until the discussion became so general in regard to a return to the simple extraction, which later on was adopted by most operators. It was not my wish to give up the iridectomy, but in the mean time, however, I had several cases in which the lens popped out through the pupil just as the section was completed—one in which I had opened the capsule with the point of the knife as it entered the anterior chamber, the patient at the moment the section was finished squeezing the eye. Another case was traumatic, in which the particle of steel could be distinctly seen in the lens, which had thoroughly lacerated the capsule. This was a fac-simile of the preceding case, the fragment of steel coming with the lens. This case, together with others, impressed upon my mind that the lens indicated a tendency to escape, and, as a natural consequence, sought the course of least resistance. Upon this hypothesis I endeavored to make the simple extraction in this way—*i. e.*, by opening the capsule with the point of the knife; but it was attended by so many failures to make the rapid extraction without injury to the iris that I abandoned it. About this time I recalled to mind the preliminary capsulotomy done with the needle in 1885, which a few months later (after returning from my summer vacation) I put into practice with the results as above given.

THE

NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by D. APPLETON & Co.

Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, SEPTEMBER 20, 1890.

THE ACTION OF MICROBIAL PRODUCTS ON MICROBES AND ON THE ORGANISM.

"MICROBES are always the indispensable cause of virulence; they are always the cause of immunity, I dare not say the indispensable cause, but they only produce their effects by means of the chemical matters that they secrete." With these words Professor Bouchard premises, in the *Revue de médecine* for July, one of the most comprehensive studies of the action of the products secreted by pathogenic micro-organisms that have appeared. The subject has been studied experimentally by the action of bacterial products on microbes; by the action, both harmful and useful, of these products on the animal organism; by the action that the products of a microbe exercise on the infection produced not only by that but also by another microbe; and by an examination of the measures by which these products influence infection, by their action both on the microbe-destroying state of the humors and on phagocytosis.

The products of the vitality of a microbe, as of all living cells, are multiple. Many of these substances are not toxic, but the toxic matters of a single kind of microbe are numerous; they are diastases, alkaloids, volatile acids, etc. And the author believes that the inoculable are distinct from the toxic matters. Among the local lesions of infection, the chemical alterations of tissue depend on diastase, but it is extremely probable that the paralysis of the leucocytes, the obstacle to phagocytosis, is due to some other toxic substances, called toxines. Infectious fever seems to be due to diastatic substances, and perhaps to certain cellular alterations that occur in the liver, kidneys, and muscles, while any nervous phenomena depend on the toxines. Whatever the substance that produces immunity, it is not believed that it is a diastase.

The conclusions deduced from the experiments seem to prove that among the substances secreted by microbes is a substance capable of injuring directly the development, multiplication, and secretion of the micro-organism, although this is indirectly favorable to the microbe by chemically modifying the environment. There are substances secreted by a microbe that are either inhibitory or favorable for microbes of other species. There are microbes that secrete substances poisonous to animals, and it is this toxicity that constitutes the virulence of a microbe.

While there are pathogenic microbes that secrete inoculable matter, it is not by its presence alone that this matter produces immunity, for in some way the inoculable matters so impress the animal organism that even when they are eliminated the humors permanently remain less propitious to the vitality of the same microbe. The inoculable substances change the activity of the cells in some fashion, so that even when eliminated the leucocytes, though confronted by the same microbe, more abundantly effect diapedesis and more energetically accomplish their phagocytic function.

Though the soluble matters of a microbe when injected at the same time with an inoculation of the same microbe render the infection more intense, yet the same matters injected some days before inoculation, far from aggravating the infection, inhibit or attenuate it. With antagonistic microbes—that is to say, those in which a simultaneous inoculation generally develops one only—it is noticed that the soluble matters of the stronger inhibit the weaker, though if injected at the same time with an inoculation of the weaker they produce a moderation and attenuation of the infection most pronounced if given in the same locality. Auxiliary microbes may, by the inoculation of one or the injection of its soluble products, allow the other to develop in an animal that is naturally refractory, though, in case the virulence of the microbe should be slowly attenuated, it would only develop in an unrefractory animal.

The bacteria-destroying condition of the animal organism produced by the injection of bacterial matters should appear at the end of the first twenty-four hours; and it is neither suppressed nor suspended by a new injection of such substances as have conferred the immunity. In animals that have a natural or acquired immunity, and that are capable of resisting a pathogenic microbe by phagocytosis, the soluble products of that microbe would inhibit phagocytosis, while in animals having no immunity, natural or acquired, but capable of resisting non-pathogenic or attenuated pathogenic microbes by phagocytosis, the products of a virulent microbe will inhibit the phagocytosis. These results prompt the question of what other substances, microbial or not, can produce the same effect on phagocytosis, or is the latter the mechanism by which they act?

ŒSOPHAGEAL VARIX A CAUSE OF HÆMATEMESIS.

SUDDEN death by hæmatemesis is a not uncommon event in cirrhosis of the liver, and cases where, without any warning, a person habitually intemperate vomits blood occur with sufficient frequency to render the study of the exact mechanism of the hæmorrhage a matter of some importance. Latterly the whole question of portal obstruction and its effects has been receiving a good deal of attention. Litten (*Berliner klinische Wochenschrift*) has been experimenting upon the circulation in the liver of dogs and studying the clinical phenomena in portal obstruction. In five cases of hepatic cirrhosis where death was caused by vomiting of blood he has found that the fatal outflow came from the rupture of enormous varicosities situated at the lower end of the œsophagus. For the whole extent of its course the gullet is richly supplied with veins, and of these the upper ones, by means of the inferior thyreoid veins, empty into the superior vena cava, while the veins supplying the lower part of the tube form above the cardia a large plexus communicating but in a very slight degree with the portal vein, and emptying mainly into the vena azygos. When, as occurs in

cirrhosis of the liver, the flow of blood in the portal vein becomes obstructed, its blood passes for the most part into the vena azygos, which conducts it directly to the superior vena cava. The blood of the gastric coronary veins and that of the gastro-duodenal veins especially passes in this direction. As a result, the vena azygos, already overloaded, can not receive all the blood of the œsophageal plexus, hence the formation of varices the rupture of which gives rise to a hæmatemesis and leads to the supposition that the vessels in the stomach have given way.

The same subject occupied the attention of the Section in Medicine at the recent meeting of the British Medical Association at Birmingham. The liability to sudden death from hæmatemesis in cases where there was no ascites, or in fact any symptoms, was emphasized in Dr. Saundby's paper on the Varieties of Hepatic Cirrhosis. Dr. Stacy Wilson's paper dealt especially with varices as a cause of hæmatemesis in cirrhosis of the liver. He drew attention to the dilatation which took place in the veins in the lower part of the œsophagus, which in some cases prevented ascites, and pointed out the effect of the sphincter of the cardiac end of the stomach in preventing the blood of the coronary vessels from getting into the œsophageal branches in normal conditions, but said that, when portal obstruction occurred, the tension in the coronary vessels overcame the action of the sphincter, and the œsophageal veins became varicose and might rupture. He thought this was a common cause of hæmatemesis. He had found œsophageal varices in five cases of hepatic cirrhosis, and in most of these there was rupture. Dr. Ratcliffe exhibited specimens of varicose ulcers in the œsophagus and one in which there was thrombosis of one of the œsophageal veins, from cases of hepatic cirrhosis in which hæmatemesis had occurred.

MINOR PARAGRAPHS.

FATAL POISONING BY MUSSELS.

Sir Charles Cameron, M. D., of Dublin, contributes to the *British Medical Journal* a preliminary note regarding the Seapoint tragedy from mussel poisoning, whereby five persons lost their lives. At Seapoint, near Dublin, a family of seven, consisting of the mother, her five children, and a maid-servant, partook of a meal of stewed mussels. They were all made sick within twenty minutes after the ingestion of the meal, and in an hour one of the children was dead. The mother and three other children succumbed before the second hour had elapsed. The symptoms began with the pain of pins and needles in the hands. Graver symptoms followed rapidly, such as vomiting, dyspnœa, swelling of the face, loss of co-ordination in movement, convulsions, and spasmodic movements of the arms. Death appeared to take place by asphyxia, the faces being intensely livid. One child and the servant, who probably ate only a few of the mussels, recovered. The pond whence the shell-fish were obtained is a small body of water to which the sea has access at high tide; it also receives fresh water and some sewage. The water at high tide shows twice as much saltness as when the tide is out. The drainage from the land is necessarily, from certain local conditions, impure. The uncooked mussels that remained at the place of poisoning differed from other mussels obtained from the open sea in having much larger livers, and their shells were very brittle. The generic tests applied, in order to discover if an alkaloid was present, clearly proved that a leucomaine existed, which, indeed, was obtained in crystals, visible under the microscope, and corresponding to the substance that Brieger has described as occurring in the poisonous mussels examined by him. The quantity of the leucomaine thus separated by Dr. Cameron was insufficient for a thorough examination, and it became necessary for him to procure a further supply of the shell-fish from the pond above mentioned. He expects to extract therefrom a substantial quantity of the leucomaine, for the purpose of a complete identification of it with the mytilotoxine, $C_6H_6NO_2$, of Brieger. The Seapoint calamity is another instance of poisonous shell-fish being the product of a foul or stagnant water. The liver of the poisonous fish becomes the seat of disease and generates the leucomaine, the disease in question probably being the result of the injurious action of its food supplied from a contaminated pond-water. Dr. Cameron states that he has examined the literature bearing upon mussel poisoning, and has found that many of the waters whence the mussels have been obtained were stagnant or impregnated with sewage.

THE AMERICAN DERMATOLOGICAL ASSOCIATION.

The Richfield meeting of the association was a most successful one. To this two factors contributed: First, the character of the scientific work; secondly, the liberal hospitality of Mr. Proctor, the owner of the new bathing establishment, and the courtesy of Dr. C. C. Ransom, the medical superintendent. Elsewhere we give an abstract of the scientific proceedings; it is our purpose now to note the social side of the meeting alone. The association assembled on a Tuesday morning in the solarium of the new bathing establishment. After dinner the members were driven around Lake Canadarago. In the evening the grounds of the Spring House were illuminated with Chinese lanterns and the members were conducted through all parts of the well-equipped bath-house. After the evening meeting a supper was given in Dr. Ransom's offices. On Wednesday afternoon, by Mr. Proctor's invitation, the members went to Lake Otsego, some twelve miles off, and partook of a fish and game dinner. The entire service of the baths was placed at their disposal for the time being. The baths themselves are deserving of special mention. For size, arrangement, and completeness they are unsurpassed. They are arranged in two corresponding halves for the two sexes, each half containing some thirty-eight separate baths with a large resting room, and a complete Turkish bath. Besides these there are a swimming bath, inhalation and pulverization rooms, gymnasia, a solarium, doctor's offices, a drinking fountain, a bazaar, a barber's shop, and a chiropodist's room. The whole establishment is watched over, as well as the persons who use it, by the very competent medical superintendent. The association elected officers for the ensuing year as follows: Dr. F. B. Greenough, of Boston, president; Dr. L. N. Denslow, of St. Paul, vice-president; and Dr. G. T. Jackson, of New York, secretary and treasurer. Four new members were elected, namely, Dr. J. A. Fordyce and Dr. C. W. Cutler, of New York; Dr. M. B. Hartzell, of Philadelphia; and Dr. J. Grindon, of St. Louis.

A NEW CULTURE FLUID.

Dr. G. M. Sternberg gives the *Medical News* a short note, interesting to laboratory-workers and others, on the use of the fluid contained in unripe cocoanuts as a culture medium. This

fluid, unlike that of the ripe nut, is devoid of all milky appearance and is perfectly transparent. By the people of the West Indies it is known as *agua coco*, or cocoannt water, and is very popular as a refreshing drink; at the railway stations and restaurants may be seen piles of the unripe nnts, which at a moment's notice can be broken open and made to yield a tumblerful of the fluid at a trifling cost. The cocoanut is a germ-proof receptacle, and, if care is taken in the removal of its fluid, the latter requires no sterilization at the time of its reception into the bacteriologist's tubes or flasks. Dr. Sternberg has been able to store it away almost indefinitely for future nse, the fluid remaining perfectly transparent and ready for immediate use. Heating the fluid will cause in it a slight precipitate. He has employed this medium quite extensively dnring the past two years, although he has been cognizant of some of its properties since 1879, and has found it of great convenience. Certain micro-organisms multiply in it more rapidly than others in consequence of its slightly acid reaction when first obtained from the nut. This reaction makes it unsuitable for cultures of certain of the pathogenic bacteria, bnt, when desired, it is a simple matter to neutralize it. A detailed chemical analysis of the fluid is given in the paper.

THE FAITH CURE AND MANSLAUGHTER.

A very sad occnrrence in connection with the faith cure is reported from Toronto. Mr. John Kent, a well-known citizen, had been the subject of diabetes for several years, but had been in a state of fair general health and in a condition to attend to his business. On the advice of his physician he had adopted a form of diet under the use of which the sugar in the nrine was said to be diminishing in quantity and the patient to be gaining in health and strength. Not satisfied with the progress he was making, he put himself in the hands of the Christian scientists, who were both numerous and popular in Toronto. The usual process of faith cure was gone through with. He was told to eat what he pleased, did so, and died of diabetic coma. A coroner's inquest was held, which ended in a verdict of manslaughter against Mrs. Stewart, the so-called scientist, "in that he (Kent) came to his death throngh the gross ignorance of Mrs. Stewart, who nndertook to cure him of his disease, in not advising him to continue the restricted diet prescribed by his former physician." The coroner, after summing up the evidence, charged directly against the accused. When cross-examined, Mrs. Stewart admitted that she knew very little of medical science. She was arrested and held in bail to stand her trial for manslaughter at the next session of the Court of Queen's Bench.

KEFIR.

Professor Uffelmann, of Vienna, has made an examination of that preparation of milk called kefir, which has recently been landed by physicians of Berlin and Paris as well as Vienna for its power of assisting stomach digestion, strengthening the nervous system, and increasing the weight of the body. According to the *Medical Press and Circular*, he finds that the kefir ferment converts the milk into alcohol, carbonic acid, hemi-albumose, and peptone compounds. The casein is broken up into small particles in combination with the fat, forming a kind of emulsion. Uffelmann holds that the lactic acid converts the casein into very fine coagula, and relieves the gastric acid of a great part of its work. The carbonic acid increases peristalsis and the flow of the gastric juice. The peptones and alcohol make the combination better borne and cause it to contribute to nutritive accumulation and assimilation. These are the reasons, he thinks, for the growing repute of kefir as a means to the rapid increase of the weight of the body.

SPERMINE.

According to *Le Mercredi médical*, Dr. Pohl, of St. Petersburg, believes that certain crystals found in semen are, as stated by Schreider, the phosphate of an organic base, spermine, that is identical, according to Laderberg and Obel, with ethylenimine. Dr. Pohl has extracted spermine from the testicles of young rabbits, and finds experimentally that it decreases the action of the heart while it increases general energy and stimulates the nervous and genital systems. He believes that the action of castoreum and musk is due to the presence of spermine.

THE URINE OF OPIUM HABITUÉS.

Dr. J. B. Mattison, of the Brooklyn Home for Habitués, writes to us concerning a statement that he has met with in contemporary periodical medical literature, to the effect that the addition of tincture of chloride of iron to the urine of a subject of the opium habit will produce a blue tint showing the presence of morphine. Dr. Mattison declares that the statement is not trne.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending September 16, 1890:

DISEASES.	Week ending Sept. 9.		Week ending Sept. 16.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	30	10	57	13
Scarlet fever	17	1	39	1
Cerebro-spinal meningitis	1	1	1	1
Measles	78	9	32	3
Diphtheria	43	14	47	19

The American Gynæcological Society.—The members in attendance at the Buffalo meeting were entertained on Thursday by the Buffalo Medical Club with an excursion to Niagara and a dinner on the return to Buffalo.

The Randall's Island Hospital.—Dr. James R. Goffe has been appointed visiting gynæcologist to the hospital.

The Jenkins Medical Association, of Yonkers, will hold its regular meeting at the house of Dr. N. A. Warren, on Thursday evening, the 25th inst. Dr. C. W. Packard, of New York, will read a paper on Surgical Insomnia.

The late Dr. Silas H. Douglas.—At a meeting of the Department of Medicine and Surgery of the University of Michigan, held on the 4th of September, 1890, the following minute was adopted, with direction that it be entered in the records of the faculty:

"Silas Hamilton Douglas, one of the founders of this department of the university and for twenty-eight years a member of this faculty, died in Ann Arbor, August 26, 1890, at the age of seventy-four years. He was one of a very few strong men of steady purpose, who opened a way for medical education in this State, and from the first determined that broader foundations should be laid for the support of medical learning. Elected as professor of chemistry in this university on August 5, 1846, he was soon active in those movements which obtained the adoption by the Board of Regents of a plan for the organization of a department of medicine, presented by Dr. Zina Pitcher and others, January 17, 1848. His interest in medicine was direct and personal; he had entered upon practice as a physician before he became a college teacher, and in the beginning of the medical school he held for a time

the chair of materia medica in addition to that of chemistry. Dr. Douglas was one of the original members of this body who have served, each in turn for a considerable period, as the dean of the faculty. Of these but one remains with us, now our honored presiding officer, a witness of the growth of medical education, rising evenly and surely upon the foundations laid by these fathers. Early in the building of the foundations Professor Douglas set out to provide for the laboratory method of study, then nearly unknown in medical schools, yet a method which has become characteristic of the finest training of the time. When Dr. Douglas had labored in the university for ten years, on May 8, 1856, the Board of Regents made provision for the erection of a building under his charge to serve as a chemical laboratory. Of this it is stated in President Tappan's annual report of the following year that it was 'one of the most complete and efficient in our country.' To this and its development Professor Douglas gave the best years of his life. It was due to the indomitable courage and unyielding perseverance strongly knit in his sturdy nature that laboratories of science gained an early and vigorous growth in this institution. And it was through his interest in medical education that medical students received the best of laboratory opportunities. A stanch defender of the interests of the Department of Medicine and Surgery, he was confident of its future strength and service. To him and his early associates in medical education a great debt of gratitude is due. We remember his services with thanksgiving and write his name with honor.

"To his family and his relatives we desire to extend our sympathies, and we invoke for them the consolations of the religious faith which he sustained."

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 31 to September 13, 1890:*

De Witt, Theodore F., First Lieutenant and Assistant Surgeon, is granted leave of absence for one month, to take effect September 15, 1890. S. O. 76, Headquarters Department of Texas, San Antonio, Texas, September 1, 1890.

Appointment.

Baxter, Jedediah H., Colonel and Chief Medical Purveyor. To be Surgeon-General, with the rank of brigadier-general, August 16, 1890, *vice* Moore, retired from active service. Headquarters of the Army, A. G. O., Washington, September 1, 1890.

By direction of the Acting Secretary of War, a board of medical officers, to consist of Vollum, Edward P., Colonel and Surgeon; Sternberg, George M., Major and Surgeon; Hartsuff, Albert, Major and Surgeon; Hopkins, William E., Captain and Assistant Surgeon, is constituted to meet in New York city on October 15, 1890, or as soon thereafter as practicable, for the examination of candidates for admission into the medical corps of the army. Par. 8, S. O. 213, A. G. O., Washington, D. C., September 11, 1890.

Corson, Joseph K., Major and Surgeon, is relieved from duty at Fort Sherman, Idaho, by direction of the Acting Secretary of War, and will report in person to the commanding officer, Washington Barracks, District of Columbia, for duty at that station. Par. 4, S. O. 212, A. G. O., September 10, 1890.

By direction of the Acting Secretary of War, the following changes in the stations and duties of officers of the medical department are ordered: Heizmann, Charles L., Major and Surgeon, is relieved from duty at San Antonio, Texas, and will report in person to the commanding officer at Fort Clark, Texas, for duty at that station, to relieve Moseley, Edward B., Captain and Assistant Surgeon, who, upon being relieved by Major Heizmann, will report in person to the commanding officer at San Antonio, Texas, for duty at that station. Par. 23, S. O. 211, A. G. O., Washington, D. C., September 9, 1890.

Carter, Edward C., Captain and Assistant Surgeon, is granted leave of absence for one month. Par. 2, S. O. 108, Headquarters Department of the Columbia, September 6, 1890.

Jarvis, Nathan S., First Lieutenant and Assistant Surgeon, is relieved from duty at Fort Verde, Arizona Territory, by direction of the Acting Secretary of War, and will report in person to the commanding officer, San Carlos, Arizona Territory, for duty at that station. Par. 2, S. O. 208, A. G. O., Washington, D. C., September 5, 1890.

Woodhull, A. A., Major and Surgeon, is granted leave of absence for one month, on surgeon's certificate of disability, with permission to go beyond the limits of the department. Par. 1, S. O. 122, Department of the Missouri, September 5, 1890.

Wood, Leonard, First Lieutenant and Assistant Surgeon. Leave of absence for one month, to take effect on or about October 20, 1890, is hereby granted, with permission to apply for an extension of one month. Par. 1, S. O. 74, Department of California, San Francisco, Cal., August 30, 1890.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending September 13, 1890:*

Wise, J. C., Surgeon. Detached from Torpedo Station and ordered to the U. S. Steamer Alliance.

Fitzsimons, Paul, Surgeon. Ordered to the Torpedo Station, Newport, R. I.

Bright, George A., Surgeon. Detached from the U. S. Steamer Constellation and ordered to Naval Academy.

Olcott, F. W., Assistant Surgeon. Promoted to be Passed Assistant Surgeon.

Wentworth, A. R., Passed Assistant Surgeon, requests to withdraw resignation. Granted.

Crawford, M. H., Passed Assistant Surgeon. Detached from the U. S Steamer Monongahela and granted two months leave of absence.

Keeney, James F., Assistant Surgeon. Detached from the U. S. Steamer Richmond and granted two months leave of absence.

Lowndes, Charles H. T., Assistant Surgeon. Detached from Naval Academy and ordered to the U. S. Steamer Richmond.

Woolverton, Theoron, Medical Director. Ordered to the U. S. Steamer Philadelphia. September 15, 1890.

Penrose, Thomas N., Medical Inspector. Detached from the U. S. Steamer Richmond.

Gardner, J. E., Passed Assistant Surgeon. Detached from the U. S. Fish-Commission Steamer Albatross.

Drake, N. H., Passed Assistant Surgeon. Detached from the U. S. Coast-Survey Steamer McArthur, and ordered to the U. S. Fish-Commission Steamer Albatross.

Berryhill, T. A., Passed Assistant Surgeon. Detached from the Hospital, Mare Island, Californuia, and ordered to the U. S. Coast-Survey Steamer McArthur.

Heffinger, A. C., Passed Assistant Surgeon. Ordered before Retiring Board, October 1, 1890.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service from August 12 to September 6, 1890:*

Vansant, John, Surgeon. Granted leave of absence for thirty days, to take effect upon return of Assistant Surgeon J. C. Perry to duty. September 5, 1890.

Wyman, Walter, Surgeon. To proceed to Cape Charles Quarantine Station, on special duty. August 25, 1890.

Stoner, George W., Surgeon. Granted leave of absence for four days. August 19, 1890.

Carmichael, D. A., Passed Assistant Surgeon. Leave of absence extended fifteen days. August 26, 1890.

Ames, R. P. M., Passed Assistant Surgeon. To proceed to Memphis, Tenn., on temporary duty.

Devan, S. C., Passed Assistant Surgeon. Leave extended five days on account of sickness. August 12, 1890.

Williams, L. L., Passed Assistant Surgeon. Granted leave of absence for thirty days. September 5, 1890.

Goodwin, H. F., Assistant Surgeon. Granted leave of absence for thirty days. August 21, 1890.

Cobb, J. O., Assistant Surgeon. To proceed to Marine Hospital, Detroit, Mich., for duty. August 16, 1890.

Hussey, S. H., Assistant Surgeon. Granted leave of absence for thirty days. August 19, 1890.

Perry, J. C., Assistant Surgeon. Granted leave of absence for twenty days, to take effect when relieved. September 3, 1890.

Young, G. B., Assistant Surgeon. To rejoin his station at St. Louis, Mo., when relieved. September 3, 1890.

Appointment.

Rosenau, Milton J., Assistant Surgeon. Commissioned as an Assistant Surgeon by the President, August 25, 1890. Ordered to Chicago, Ill., for temporary duty. August 27, 1890.

Society Meetings for the Coming Week:

Monday, *September 22d:* Medical Society of the County of New York; Boston Society for Medical Improvement; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

Tuesday, *September 23d:* New York Dermatological Society (private); Buffalo Obstetrical Society (private); Medical Society of the County of Lewis (quarterly), N. Y.

Wednesday, *September 24th:* New York Pathological Society; American Microscopical Society of the City of New York; Medical Society of the County of Albany, N. Y.; Auburn City, N. Y., Medical Association; Berkshire, Mass., District Medical Society (Pittsfield).

Thursday, *September 25th:* New York Orthopædic Society; Brooklyn Pathological Society; Roxbury, Mass., Society for Medical Improvement (private); New London, Conn., County Medical Society (Extra—New London); Pathological Society of Philadelphia.

Friday, *September 26th:* Yorkville Medical Association (private); New York Society of German Physicians; New York Clinical Society (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

Letters to the Editor.

HÆMORRHAGE AFTER AMYGDALOTOMY.

Saratoga Springs, N. Y., *September 8, 1890.*

To the Editor of the New York Medical Journal:

Sir: I have read with much interest Dr. Jonathan Wright's article on Hæmorrhage after Amygdalotomy, in the *Journal* for August 30th, and would report two cases that have occurred in my practice. The first was in a boy, eleven years old. The hypertrophied right tonsil was removed with Mathieu's amygdalotome in March, 1882. The hæmorrhage was quite profuse, but was controlled with styptic applications and pressure on the cut surface, with ice externally and counter-pressure. The other case was that of a young lady, eighteen years old, weighing nearly two hundred pounds, and extremely nervous. I had attended her about ten years before in a fairly serious attack of scarlet fever, and at that time both tonsils were somewhat hypertrophied. I advised their removal as soon as she was well from the fever, but nothing was done till the winter of 1889, when I used Donaldson's treatment (by small incisions and the insertion of a crystal of chromic acid into each cut), but with little or no effect. The removal of the tonsils was declined at that time. Both tonsils were now very large, the left one pushing the uvula to one side. On June 29, 1889, I amputated the right tonsil, having injected a ten-per-cent. solution of cocaine into it. Rest and a tannogallic-acid gargle were used after the operation; the bleeding was very slight, and there was little or no pain. On July 14th I removed the left tonsil in the same manner. It was hard and leathery. There was no pain in its removal, but there was a little more bleeding than at the other operation. I left the patient comfortable an hour later, but within another hour I was called, and found that she had had profuse hæmorrhage; she was pale, had no pulse at the wrist, and had fainted two or three times. The bleeding was controlled by applying sponges saturated with solution of persulphate of iron to the wound and ice externally, firm pressure being made and kept up for an hour, and stimulants, ergot, gallic acid, and opium given internally. She made a good recovery, being of course under treatment for some time for the resulting anæmia. The instrument used was the same as the one employed on the boy.

W. H. Hall, M. D.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

Meeting of May 14, 1890.

The President, Dr. C. K. Briddon, in the Chair.

Laparo-colotomy for Stricture of the Rectum.—The President read a paper with this title. (See page 310.)

Calculus of the Kidney; Removal of the Organ.—Dr. A. G. Gerster presented a woman, aged fifty-six, who, six years before, had experienced some marked pain in the hypogastric region, pain on micturition, and rigors. The urine was turbid. Alternating with periods of abeyance, this condition had continued four years. Two years ago intense pain had initiated the appearance of a tumor in the left loin. Fourteen months ago abscess was diagnosticated, and, on incision, a quantity of pus was evacuated. After this the general condition had somewhat improved. On her admission into Mount Sinai Hospital a discharging sinus was found in the left lumbar region, leading down to a slightly movable tumor, readily made out on bimanual palpation. The tortuosity of the sinus had prevented the probe entering more than two inches. At this time the urine was about normal as to quantity, but contained much pus, albumin, and blood, but no casts. There seemed no reasonable doubt that a diseased kidney would be found at the bottom of the sinus, and operative interference was arranged for. The right kidney being first made out by palpation, the left was then exposed by a slightly oblique, nearly transverse incision, four inches in length, carried through the loin. The sinus was seen leading into the pelvis of the organ, which was much shrunken and peculiarly lobulated. After it was peeled out of its fibrous capsule, an elastic ligature was thrown around the vessels and ureter, just in front of the hilum. When the kidney was cut away, a small stone was found to have been caught in the ligature, but this came away on gentle traction. The pelvis of the kidney contained a number of uric-acid stones and about two ounces of thick pus. The secreting tissue of the organ was found replaced by cicatricial masses. During the attempt at liberating the kidney a rent was accidentally made in a protruding fold of the peritonæum. This was closed by a few catgut sutures. The wound was then packed with iodoform gauze and the patient put to bed in a slightly collapsed condition. On the day following, the temperature was 99° F., the urine scanty, but the general condition good. The next day twenty-four ounces and a half of urine were passed in the twenty-four hours. The urine at first contained considerable pus, casts, and renal epithelium, but these gradually disappeared. The ligature came away in about three weeks, and the wound was then closed by secondary suture. In three weeks more the patient was discharged cured, with a slight trace of pus in the urine. The muscles had reunited without any difficulty, and the patient made no complaint of any disability in moving her trunk. Her general condition had very much improved since the operation,

though the speaker did not believe the other kidney was actually sound. The specimen he presented showed how shrunken the organ was.

Dr. L. A. Stimson asked if the descending colon had been recognized.

Dr. Gerster said it had not come into view. The intestine which had protruded was small intestine. He must have come into very close proximity to the colon, but after the accident he had not continued to work in the fat surrounding the cicatricial masses.

The President asked whether the incision would be applicable to a large kidney.

Dr. Gerster believed that it gave more space than any single incision he had ever tried. The secondary suture had been a very simple affair, and had aided the closure of the very large wound through the muscle.

Dr. Stimson thought it showed the advantage of doing the operation at separate sittings.

The President asked if it did not render the secondary operation difficult from the fact of the cicatricial tissue clinging to the wound.

Dr. Gerster replied that the easiest operations he had done had been secondary, and the most difficult had been the primary operations.

The President said his experience had been just the reverse.

Dr. Gerster said that, in attempting to follow the line of the sinus, it was difficult, but if the incision was made in any cicatricial tissue, it could be carried through perfectly normal tissue, and the kidney recognized as easily as in the primary operation. He believed, however, that it would not do to pass a hasty judgment on the respective merits of these two methods. The primary operation had the great advantage that, after splitting the fatty capsule and enucleating the kidney with its own primary capsule, the treatment of the pedicle became much more easy. It did not leave behind a mass of pedicle which compelled the adoption of open treatment. The wound might be closed, and only a drainage-tube left in.

Abscess of the Liver.—Dr. J. A. Wyeth presented a patient who had come to him some four months before after having been in one of the city hospitals for a considerable time for a tumor in the region of the liver. Examination by the speaker resulted in a diagnosis of abscess of the liver. Incision over the most prominent part of the tumor resulted in the evacuation of a large quantity of pus, with liver tissue. The cavity was then scraped out. The man recovered rapidly and was now entirely well. A small tube was still in the wound, through which there escaped about ten minims of a sero-purulent fluid daily. There was no history which had pointed to the causation in this case. The man had always lived in this climate.

The President said that these cases were unusual in this climate. He had operated in quite a number, and during one term of service he had had three cases of liver abscess in the wards of the Presbyterian Hospital at one time, and two of these were of unusual interest. One patient was brought into the hospital suffering from suppurative peritonitis due to rupture of an abscess into the abdominal cavity; a physical examination revealed hepatic dullness high up, and an incision between two ribs permitted the finger to pass through the adherent pleura and into the substance of the liver itself. Guided by the finger, a very large curved trocar was passed into the cavity of an abscess that communicated with the peritonæum. The speaker then opened the peritonæum in both inguinal regions, passed a drainage-tube through from one to the other, and irrigated the cavity of the peritonæum through a tube introduced into the opening made in the abscess and intercostal space.

One of the other cases was still more remarkable. An old woman was in the medical wards of the hospital, and a very thorough examination and extended observation had warranted the physician in charge in expressing the opinion that she was the subject of liver abscess. She was jaundiced, her liver projected several inches below the free border of the ribs, and she had very severe and irregular rigors. The speaker made an incision about two inches long, and parallel with the border of the ribs, on the right side. When the peritonæum was cleanly exposed it was evident that there were no adhesions between the convex surface of the liver and the abdominal wall, and the organ could be seen moving up and down, as influenced by respiration. The wound was packed with gauze, and, five days after, the liver was needled in various directions through the bottom of the wound without detecting pus. After scraping the surface of the wound and making it aseptic, he opened the abdominal cavity, extending the incision across the median line a distance of five or six inches. He then satisfactorily demonstrated to the gentlemen present that there was no abscess. Nearly the whole of the free convex surface of the liver was critically examined, and then the organ was rotated on its transverse axis, so as to expose a large portion of its lower surface; it looked like a liver in the early stage of cirrhosis; its surface was finely tuberculated and rosy red in color; the ligamentum suspensorium hepatis was very much enlarged and œdematous—so much so that at first it was supposed to be a knuckle of intestine. The whole operation was done under the strictest antiseptic precautions, and the abdominal wound was carefully closed. He was very much surprised at the very remarkable result that followed this apparently harsh procedure. The patient had no more chills, recovered from the effects of the operation without accident, and left the hospital in a few weeks.

Referring to the presence of the drainage-tube in Dr. Wyeth's patient, the president would warn against the possible danger of the tube's being drawn into the sinus or cavity by inspiration. He had recorded one case in which he had operated for the evacuation of a large quantity of bile, due to extensive rupture of the liver, and so encapsulated that the peritonæum was not invaded. Three days before operating he had removed between sixty and seventy ounces of apparently pure bile by the needle, and had given prompt relief, but it was only of short duration, and a free incision had given exit to as much more. A large drain, eight or nine inches long, was introduced, and bile had continued to flow through it for several months. One afternoon he was informed that the tube was missing, and he made an ineffectual attempt to find it. He then suspected that the patient had taken it out and made away with it, but this was stoutly denied. When informed that it would be necessary to perform a possible serious operation to find it, the patient still denied that he had interfered with it. He was etherized, and a long and tedious effort was made with lithotrites and variously shaped snares. The sinus was a tortuous one, and appeared to lead into a cavity situated behind the middle of the sternum. On subsequent occasions attempts were made, but the tube was never found. The discharge gradually diminished, but never entirely ceased. The patient gained in health and strength sufficiently to resume his occupation—that of a brick-maker.

Dr. Gerster thought that in the case in which so much manipulation of the liver had been done the result might have been the dislodgment of some obstruction in the gall-bladder.

Operative Procedures in the Bone Diseases of Childhood was the title of a paper read by Dr. V. P. Gibney. (See page 181.)

Dr. Stimson said the statements as to the superiority of ar-

threctomy in the treatment of diseases of the knee, if by that was meant extirpation of the capsule alone, were not borne out by his experience. Extirpation of the capsule alone, in his experience, had been followed by return of the disease and recourse to excision in every case. He was surprised to hear that excision of the knee joint had not given Dr. Gibney good results. The speaker was under the impression that it was the general experience that this operation did not contain many elements of danger to the patient's life, and that it was generally followed by permanent, satisfactory, and complete recovery. Of course, he did not mean recovery in every case, but as an operation for tubercular disease it was the one which, in his experience, had given the best results.

Dr. GERSTER thought that all cases could not be judged by one standard. A distinction must be made between tuberculous joints in children and those in adults, and different principles must obtain in practice. When it was remembered that a very large number of the tuberculous knee joints occurred among the poorer classes, with whom prolonged treatment was impossible, there was no alternative but to amputate the limb or excise the joint. Undoubtedly in children the removal of the capsular ligament and semilunar cartilages yielded excellent results at certain hands. He had read many reports to this effect by authors of note, and believed that for children the method certainly deserved trial before excision.

Dr. WYETH said that his ideas on this subject led him rather decidedly into the operative field for the treatment of knee-joint troubles, regardless of the age of the child. In the five or six cases operated on by him this winter the patients had all been from twelve to fifteen years of age. He thought it rare to meet with a child under five years with a tuberculous osteo-arthritis at the knee. He had never given much consideration to the question of lack of development in the bones, because he believed that persistent meddling with the joint for from one to five years, which might anyway end in ankylosis or something more serious, was fraught with such danger that he was inclined to discourage delay and deal promptly with these joints by excision. He could not recall a single instance in his experience of death resulting from excision of the knee joint, except, of course, in some traumatic cases. He thought the operation was an exceedingly safe one. He thought it imperative that permanent drainage should be established. This was especially important in hip-joint disease where a clean arthrectomy, with excision, was not made.

Dr. F. KAMMERER thought the question of the merits of arthrectomy or excision was still *sub judice*. He had resected a great many times, and had generally found the focus of the trouble in the bone itself. He considered the conservative treatment suggested by Dr. Gibney as perfectly in place. He had on the Continent witnessed many resections which ought never to have been done. The moment crepitus was felt it was the signal for resection, decapitation, or subtrochanteric resection when conservative measures would undoubtedly have given much better results.

Dr. GIBNEY said that he felt with Dr. Stimson that excision of the knee for adults was the thing to do, but the line had to be drawn between children and older children and adults. By arthrectomy he meant complete eradication of the capsule with the cartilage and entire removal of any diseased foci. He believed that it was the custom to wait too long in the case of adults. They were told to put the joints at rest. The joints gradually got unstable, abscess appeared, and the patient was then allowed to go around waiting for the abscess to mature. These cases were much better taken hold of early, the disease excised, and the patients thus insured good sound limbs upon which they could earn a living.

Perforating Wound of the Heart; Survival for Eighteen Hours.—Dr. STIMSON showed a heart which had been taken from an Italian, thirty-two years of age, who had been stabbed in seven places in the chest, abdomen, and arms. He had been brought to the Chambers Street Hospital in a state of profound shock, his condition being such that no surgical interference was deemed justifiable, and he died eighteen hours later. The knife had penetrated the wall of the chest an inch to the right of the left nipple, and perforated the right ventricle, making a wound one quarter of an inch long on its anterior surface, one third of an inch below the anterior cusp of the semilunar valve of the pulmonary artery, and just puncturing the opposite wall an inch and a half from the posterior interventricular septum. The valves and the chordæ tendineæ were uninjured. He had also a wound three quarters of an inch long situated two inches and a half below and two inches to the left of the umbilicus, which penetrated the abdominal cavity, but had not wounded any of the viscera.

Meeting of May 28, 1890.

The President, Dr. C. K. BRIDDON, in the Chair.

Injury from the Use of Esmarch's Bandage.—Dr. L. A. STIMSON presented a young man who had come under treatment last March for a non-suppurative tubercular affection of the right wrist, for which excision of the wrist was resorted to. The Esmarch bandage was applied in the usual manner, with the rubber tourniquet about the middle of the arm. The wound had healed without incident, but the patient was now, two months since the operation, unable to move any of the muscles of the forearm or hand. The galvanic current showed some reaction, and the speaker thought he was able to provoke contraction of some of the muscles by application of the current to the brachial plexus. The evidence was, however, not very positive. The patient had been examined by Dr. Starr, who thought the paralysis was due either to contusion of the nerves of the arm by the cord applied during the operation, or else to the temporary ischæmia of the muscles produced at the same time. Innervation through the three main trunks was completely lost, the reaction of degeneration was very marked, and the change seemed to be especially marked in the interossei muscles. According to Dr. Starr, the prognosis was good. The case seemed of interest because of the very general use of the means which appeared in this instance responsible for the trouble.

Dr. C. MCBURNEY asked what form of constricting band had been used.

Dr. STIMSON replied that he thought it was a large rubber tube.

Dr. MCBURNEY did not think this so good as the broad band, because of its enormously increased contusing force. He had frequently seen the skin rise between the turns of rubber band. He thought this form of band far more likely to cause mischief both to the skin and to the parts beneath. He would suggest that possibly this might have acted as a cause of the trouble in this case. The difficulty might be avoided by using a very broad band. A three-inch band wound a good many times about the arm would give very little evidence upon the skin of its application.

The PRESIDENT said he had seen two cases in which trouble had arisen from this bandaging, and it had followed the use of the narrow band, either as a tube or in the solid form.

Dr. STIMSON said that this was not a cord, but a hollow tube which flattened out during its application. He doubted if the breadth of the band was an important feature, and thought the danger lay rather in unduly multiplying the number of superimposed turns of the bandage about the limbs.

Dr. Gerster reported four cases in which trouble had followed the use of the broad band. He did not wish to say that the narrow band was harmless. The difficulty did not depend upon the band, but upon the traction exercised and the amount of soft tissue involved. It was a general failing to use more force and compression than was necessary. It was his custom, when dealing with the upper extremities, to have an assistant hold the radial pulse and to allow one more turn of the bandage after the pulse was reported gone.

Irreducible Intracoracoid Luxation of the Head of the Humerus; Operation.—Dr. Stimson presented a man, fifty-three years of age, who last April had fallen into the water from a row-boat in which he was standing. He had swum a few feet to a neighboring tug, into which he was lifted by his extended arms. He immediately felt severe pain in the shoulders and arms, and was brought to the Chambers Street Hospital. It was there found that he had a dislocation of each shoulder. On the right side it was well marked, the head of the humerus lying below and a little to the inner side of the coracoid process. On the left side the head of the humerus lay farther inward, the case being one of well-marked intracoracoid dislocation. The dislocation on the right side was reduced without much difficulty under ether. All efforts to reduce the one on the left side failed. The condition of things was explained to the patient, and an operation was performed on the following day. On exposing the joint cavity by an anterior incision, the condition of things at once became clear. The head of the humerus lay well to the inner side, and its neck was crossed on its outer side and above by the untorn tendon of the subscapularis muscle. After division of this tendon the head of the bone was easily returned to its place. The patient had made an uneventful recovery so far as the wound was concerned. There was now a decided droop of the head of the right humerus, with paralysis of the deltoid. On the left side the arm was quite powerless, and considerably swollen. The speaker did not think that this swelling had arisen from any interference with the vein, but thought that it was probably due to interference with the lymphatic return or to some damage of the nerve supply of the limb.

Fracture of the Patella; Treatment by Arthrotomy and the Use of Silk Suture.—The third case presented by Dr. Stimson was one of fracture of the patella. The speaker had expressed his opinion that the open operation, with suture of the fragments, was only to be done in exceptional cases, and this was a case of that type. He presented the case to call attention to certain modifications in the method. The patient, a man, forty-six years of age, had fallen from a considerable height and had fractured his right patella and also both bones of his leg, and had sustained other injuries. The fracture of the patella was slightly comminuted. There was a large and deep bruise of the soft parts of the front of the knee, which made it probable that sloughing would ensue, and this, in the speaker's opinion, contra-indicated the employment of his usual method. He had therefore done the open operation under cocaine. He had made a vertical incision over the patella, exposing the seat of the fracture. It was of a variety which he had never before encountered. It was oblique from below upward and backward, and the lower fragment was chipped at its edge. Along the line of fracture two pieces were loose and were removed. Instead of suturing the bone, he had applied a mediate suture of it through the tendon of the quadriceps and the ligamentum patellæ, as in the subcutaneous method. The external wound was then closed, and the patient put to bed with the limb in plaster of Paris. This dressing was left on seven days. After the second dressing the splints were kept on four weeks. The patient now had forty-five degrees of flexion. This modification of mediate suture of silk, passed through the tendon of the quadriceps and the ligamentum patellæ, removed some of the objections to the metallic suture. It was easy of application, and, so far as could be judged by a single application, would yield an equally good result.

Dr. McBurney thought the operation was a very admirable application of a very good principle. Many of his hearers could recall cases of very acute suppuration following the introduction of a single wire.

Two Cases of Extirpation of the Penis for Cancer.—Dr. F. Kammerer presented two patients upon whom he had performed extirpation of the penis. The organ had seemed so far involved that amputation was not deemed advisable. This method, though practiced for the first time more than fifty years ago, was not of frequent application. The author thought, however, that it gave the best guarantee of radical removal of all diseased parts, and had the advantage of removing the external orifice of the urethra into the perinæum. Both cases were of far-advanced infiltration of the corpora cavernosa, with secondary infiltration of the inguinal glands. The operation was begun by an elliptical incision at the root of the penis; from its lower point the incision was continued through the scrotum and carried down to the corpus spongiosum of the urethra. The testicles were held backward and the ischial and pubic veins of the corpora cavernosa were exposed by dissection. This was continued over the upper surface of the penis toward the rami of the pubes, separating the suspensory ligament and bringing the dorsal veins into view. When the penis was drawn down and away from the arcus pubis the vessels were so much on the stretch that it proved difficult to free them from the tissue in which they were imbedded to a sufficient extent to allow of the passage of a ligature. The operator had, therefore, resorted in both cases to the expedient of cutting through the spongy portion of the urethra immediately before the bulbous and separating it from the corpora cavernosa. The index finger of the left hand was then passed from below into the angle formed by the corpora cavernosa, when no difficulty was found in ligating the vessels. He now cut away the corpora from the ischial veins, which practically ended the operation. The urethra was fastened in the perinæum, the scrotum united by sutures. The glands were removed about ten days later, which seemed to the operator a better plan than that of removing them at the time of the first operation, thus avoiding infection of the inguinal wound from an ulcerating cancer and allowing the glandular infiltration in the groin time to subside if any of it was due to absorption from the ulcerated surface of the cancer.

Pancreatic Cyst.—Dr. Kammerer presented a patient upon whom he had operated for pancreatic cyst. Last January the patient, while pulling a truck, experienced sudden pain in the region of the stomach and grew faint. He vomited soon after. During the following days pain and vomiting continued. From that time the patient had been the subject of paroxysms of pain, chiefly during and after meals, but also at other intervals, in the epigastric region. He first noticed a swelling about three weeks after the accident. The paroxysms had become much less intense until about six weeks ago, when the tumor began to increase in size rapidly. About four weeks ago a round point, afterward becoming of about the size of a man's head, appeared, occupying the epigastric and left hypochondriac region; distinct fluctuation could be elicited, and puncture drew out a yellowish fluid, alkaline in reaction, containing considerable albumin, but no ferments, uric acid, or hooklets. The stomach was found on the upper and the colon on the lower border of this tumor, which was now movable and showed marked transmitted pulsation. At the operation the peritoneal cavity

was opened over the most prominent part of the tumor. It was found that the cyst had, as had been diagnosticated, developed in the bursa omentalis, having on its anterior surface the gastro-colic ligament firmly adherent to the cyst wall. The transverse colon crossed the abdominal incision (from the ensiform cartilage to the umbilicus) a little below its middle, leaving a space of only about two inches between the stomach and colon for an incision of the cyst. The lower part of the abdominal incision was closed far enough to cover the colon. The adherent gastro-colic ligament was sewed to the parietal peritonæum at the abdominal incision. Ten days afterward the cyst was incised with the galvano-cautery. There was considerable hæmorrhage from the vessels in the gastro-colic ligament. About two quarts and a half of the before-mentioned fluid were evacuated. The smallness of the incision did not admit of an ocular inspection of the cavity. A good-sized drainage-tube was introduced. The walls of the cyst continued to secrete copiously during the first week, but during the second week the cavity shrank rapidly, and now only a small sinus led into the abdomen for about two or three inches. The location of the tumor, its topographical relation to the stomach and colon, the history of traumatism, the rapid growth, and the colicky pains left one in doubt as to the nature of the cyst and as to whether the absence of some or all of the components of pancreatic fluid in the contents of the tumor proved anything in favor of or against the diagnosis of cyst of the pancreas.

Cancer of the Rectum; Operation; no Recurrence after Five Years.—Dr. GERSTER showed a patient upon whom he had operated in November, 1884, for cancer of the rectum. At this time about five inches and a half of the rectum were removed. A secondary operation was performed for the purpose of insuring a practicable sphincter. There had been no recurrence of the disease for five years. The patient had married and both his children were born with marked anal stenosis.

Dr. KAMMERER said it had been his experience that cancers of the rectum gave a better prognosis than cancers elsewhere.

An Essay upon the Classification of the various Forms of Appendicitis and Perityphlitic Abscess, with Practical Conclusions.—This was the title of a paper by Dr. A. G. GERSTER. (See page 6.)

The discussion of this paper was postponed until next October.

Recurrent Appendicitis.—Dr. MCBURNEY narrated the following history: J. K. C., aged thirty-nine years. Family history entirely negative. The patient, with the exception of being subject to dyspepsia and having had occasional attacks of colic when a small boy, had always enjoyed good health previous to his first attack. He had had six attacks in all, occurring as follows: March 2, 1889, April 13, June 15, September 13, November 2, and March 26, 1890. In each of these attacks, with the exception of the second, in which the pain was located in the left iliac fossa, the pain began along a line a little above the umbilicus and settled more or less quickly in the right iliac region. The point of most acute pain had been in each case, with the exception mentioned, two inches from the right anterior superior spine toward the umbilicus. All the attacks had been considered intestinal obstruction, and all had been treated with morphine and enemata. After the last attack some soreness had remained in the right iliac region for a long time. The bowels were kept regular with a laxative mixture. On his admission to the hospital, May 17, 1890, the patient seemed to be fairly nourished. There was no prostration. Pressure at the point named caused pain. Pressure elsewhere on the abdomen caused some discomfort, but there was nothing definite except at that particular point. On deep pressure the appendix could be readily felt. It was somewhat thickened and movable and extended from the point named downward and inward along the internal border of the rectus. An operation was performed on May 20th. The usual incisions were made. The appendix was found to be an inch and a half long, lying posteriorly and pointing down and to the right. There were no adhesions among the intestines. The appendix itself had a mesentery and was bound firmly to the gut by adhesions. It was hard and thickened by chronic inflammation. Heavy catgut suture was applied to the base of the appendix, which was then cut through and carefully separated from the mesentery and adhesions and removed. On account of a few drops of yellowish fluid which escaped at the base of the appendix, this part of the wound was packed with iodoform gauze. A drainage-tube was also inserted at this point. There was no irrigating of the abdominal cavity. The upper part of the wound was then sutured with heavy silk passed through peritonæum, muscle, and skin, superficial skin sutures and finally an iodoform dressing being used. The dressing was removed for the first time on May 25th, five days after the operation. The wound was clean, there was no pus, and the packing was removed. From this time on the patient had made an uninterrupted recovery.

Acute Appendicitis.—Dr. MCBURNEY also related the following: T. H., aged twenty-three years. Family and personal history negative. The patient had never had a previous attack. On March 25th, about 8 P. M., he first felt a pain in his right inguinal region, like a stitch in his side, as he expressed it. By the end of twenty minutes the pain had become so intense that he nearly fainted. This pain kept up all night without intermission, except that, about 2 A. M., he experienced some slight relief for a short time, but did not sleep. A physician had been called in within half an hour after the attack began, and nine hypodermics were given during the night—about a grain and a half of morphine in all. No great relief was afforded; the pain was so severe that the patient was said to have been semi-delirious in consequence. The bowels were constipated during the attack. The patient was admitted to the hospital on March 26th, at 10 P. M. At that time there was severe pain in the right inguinal region. There was a point of tenderness two inches to the inner side of the anterior superior spine of the ilium on the right side. This point was quite circumscribed, and a slight tumefaction was felt on deep pressure. There was some tympanites. An operation was performed at 11 P. M. The intestines were not adherent; the appendix pointed upward, slightly backward, and to the right. It was stiff, but was not perforated. There were a few old adhesions about it. The adhesions and the mesentery of the appendix were ligated with catgut and divided. A few oozing points were touched with the Paquelin cautery, and the appendix was ligated at its base, cut off, and removed. It was found to be filled with a mass of fæcal concretions, and there was a slight catarrhal condition of its mucous membrane. There was no irrigation of the abdominal cavity and no drainage, but the wound was completely closed. The dressings were of iodoform and bichloride of mercury. The patient had made a progressive recovery and was discharged, April 22d, cured.

Cystoscopy.—Dr. WILLY MEYER showed a specimen of a tumor of the bladder which had been diagnosticated by means of the cystoscope. The patient was a man, forty-four years of age, who had presented the ordinary characteristic symptoms. The growth was removed by suprapubic cystotomy.

Cancer of the Pharynx and Œsophagus.—Dr. KAMMERER exhibited a specimen of cancer of the pharynx and œsophagus which was of interest from a diagnostic point of view. The disease was of nine months' standing. Four months before, the diagnosis of cancer of the posterior wall of the larynx had been made by a competent laryngologist. Of late the patient

had been able to swallow liquids only. There were never any symptoms of dyspnœa. Externally a distinct thickening, corresponding to the upper part of the œsophagus, could be plainly felt behind the larynx, but it was deemed probable that the œsophagus might be reached below the tumor from the neck by œsophagotomy. This attempt failed, and gastrotomy was performed as a last resort. The patient died from exhaustion two days later. The post-mortem showed that the tumor occupied about six inches of the pharynx and œsophagus, although so great an extent of the tumor could hardly have been assumed. The larynx was intact.

Portable Suture Reels.—The President showed a glass apparatus constructed with a view to the convenient and safe carrying of sterilized sutures of gut or silk. He thought the arrangement the best he had seen, and had demonstrated that it would stand rough handling without injury to itself or its contents.

Impervious Penile Urethra complicated with Impacted Calculi in the Membranous Urethra and in the Bladder.—The President reported the following case: D. McC., aged forty-nine, entered the Presbyterian Hospital on January 14, 1890, with the following history: For four years he had not been able to pass any urine through the urethra. It had all come through several sinuses in the right side of the scrotum. There was a history of gonorrhœa in early life. Examination of the urethra revealed the presence of several strictures, varying in size from that of a No. 2 to that of a filiform bougie. The urethra became impervious at five inches from the meatus. In the right side of the scrotum there were found several sinuses, close together, from which urine constantly dribbled. There was considerable excoriation in this region, with marked induration of the tissues of the right side of the scrotum. The urine was alkaline and contained five per cent. of albumin, with pus and phosphates. The general nutrition of the patient was so impaired that he was put on tonic treatment previous to an operation. On February 17th ether was administered. A probe was passed into the opening in the side of the scrotum with the hope that the urethra might be entered, but the course was so serpentine that the canal was not found. This tortuous scrotal sinus was divided, and the incision was then continued into the median line posteriorly and carefully deepened, for there was no guide. At this stage in the operation the granulation tissue was thoroughly scraped away. This revealed an opening in the apex of the wound leading toward the penile urethra. It admitted only a filiform bougie, and for only an inch. Further section in the median line cut through the cicatricial tissue, and after more diligent search the opening into the urethra was found, not in the median line, but well over to the ramus of the ischium on the right side. A filiform bougie was then passed through the penile urethra and was then armed with a fine silk thread to which was attached a lozenge-shaped blade with blunt corners at the obtuse angles. This was drawn through, dividing the structures so that a No. 30 sound could be passed easily. On exploration, the proximal end of the urethra was found dilated into a cavity containing a number of soft calculi and a considerable quantity of sabulous matter. This cavity was distinct from the prostatic portion of the urethra and bladder. In the bladder there were found three calculi, varying in size from that of a split pea to an inch in length by half an inch in diameter; these were removed by dilating the prostatic portion of the urethra. The subsequent treatment of the case consisted of frequent irrigation of the bladder and the passage of a sound every four days. The recovery was uneventful. The urine became normal, the patient gained rapidly in flesh and strength, the wound healed kindly, and he left the hospital, cured, on April 16th.

AMERICAN DERMATOLOGICAL ASSOCIATION.

Fourteenth Annual Meeting, held at Richfield Springs, September 2, 3, and 4, 1890.

The President, Dr. Prince A. Morrow, of New York, in the Chair.

The President's Address.—The address dealt first with the present position of dermatology. Those engaged in this specialty had abundant cause for congratulation. Only a few years ago dermatology had little standing in this country. Previous to 1876 only twelve schools gave special instruction in this department. To-day dermatology was recognized in the teaching faculty in eighty-six schools, and perhaps more. He asked, however, whether this showed a healthy growth or merely a mushroom growth. There was reason to believe that there were many and grave defects in the existing system of instruction. It was not the amount but the quality and efficiency of the instruction that constituted the criterion of its value. For the successful teaching of dermatology two conditions were essential, namely, capacity in the instructor and abundance and variety of clinical material. It must be admitted that the capacity of some of the teachers in our medical schools was doubtful, while the clinical material in the majority of cases was inadequate. Even in large cities the clinical material was too much dispersed—in New York, for instance. For a thorough study of cases and of the results of treatment a hospital was necessary. In medical schools cases of skin disease should be presented only to advanced students, not to those taking the first or second year's course. The study of these diseases should be obligatory, which it was not now in any school in the country, so far as he knew. If clinical material was not abundant, and the study of dermatology was made obligatory, he thought it a question whether it would not be better to leave instruction in this department to post-graduate schools. It was a question also whether this post-graduate instruction could not be better provided for in organized institutions than in independent organizations.

In the matter of nomenclature, new names were being introduced into dermatology which were not destined to retain a permanent position, and, while an essentially new disease required a new name, he would protest against the present neological craze. He suggested the propriety of introducing some subject for special discussion at the annual meetings.

Observations on Prurigo, Clinical and Pathological.—Dr. R. W. Taylor, of New York, read the paper. At the first meeting of the society Dr. Campbell had read a paper on prurigo, and it appeared that only six cases had then occurred in the experience of those present. New interest had been excited since the reading of a paper on this subject last year, in which the author gave accounts of twelve cases seen by him in Chicago. The combined experience of all present at that discussion had included only eighteen cases. Dr. Taylor thought the disease more common in America than these statements would lead one to suppose. It was probable many cases escaped recognition and were classed as eczema, scabies, phtheiriasis, ecthyma, impetigo, and even ichthyosis. This was due in part to the fact that there were no good plates representing the clinical aspects of the disease accessible to the general profession. He undertook to remedy this deficiency to some extent by giving photographs and a full description of a recent typical case, and also alluded to the casual concomitants and modifying conditions during the course of the disease. The patient was a healthy girl, aged nine, of healthy American parents, in good circumstances, and with healthful surroundings. When four years old she began to scratch, and little red pimples, which appeared on

the face, forearms, and legs, were attributed by the parents to mosquito bites. The disease had recurred every year up to the child's visit to the hospital, in January of this year. The expression of the face was then rather dull, the color being the typical white, somewhat ashy hue, of prurigo. Over the forehead, the temporal region, and the cheek there was a copious eruption of small conical papules, some whiter than the skin, others of rather a yellowish hue, and others capped with a blood crust, the result of scratching. They were not developed on the site of sebaceous glands. There was no marked dryness or want of vitality in the hair, as he had seen in severe cases; there was slight mealy desquamation in the scalp. As pointed out by Hebra, the eruption did not appear on the neck and nucha, but began to develop where the shoulder merged into the neck. The principal eruption was on the back of the hand and forearm and on the outer and anterior surface of the legs, where the papules were as large as a split pea. There were some on the arms, the buttocks, and the thighs. They were scattered without semblance of grouping, conical in shape, and firm; some of the color of the skin, others of a reddish hue, others capped with a blood crust. Variations in the appearance of the disease were observed under certain complications, and shown in photographs. Dr. Taylor read the report of Dr. Ira Van Giesen, who had studied sections under the microscope.

A Clinical Study of Pruritus Hiemalis.—Dr. W. T. Corlett, of Cleveland, read the paper. The affection had first been pointed out as a disease *sui generis* by Dr. Duhring, and at about the same time by Jonathan Hutchinson, since when it had been little written about. It was seldom seen save in certain localities—in the Southern States only during cold waves. On the southern border of Lake Erie it was well defined and not uncommon. He related three cases illustrating different points of interest connected with the disease. In one it had recurred during the cold season for over twenty-two years; in another the eruption had the appearance at times of urticarious patches, two or three inches in diameter, confined to the extremities, subsiding in about ten minutes, leaving for a while a dark-yellowish spot. The third case was in a negro, showing that that race was not exempt. The writer's experience went to show that the state of the general health had no appreciable effect on the pruritus; that the local irritation of the clothing, although capable of aggravating the malady, was not of itself able to produce it; meteorological conditions appeared to be the main ætiological factor. These were most potent with a low temperature, low humidity, and a wind blowing from the northwest. These influences were favorable to evaporation, and the low temperature reduced the glandular activity of the skin to the minimum. As a consequence, the skin became harsh, the peripheral nerves were irritated, and the disease was induced. He did not think the primary irritation could be central, else in time it would give rise to a less fleeting disease. It was not infrequently associated with other neuroses of the skin, these neuroses, however, only showing the peculiar susceptibility of the nervous system. The treatment was largely palliative. Internal medication seemed to have little effect. Locally he had used ichthyol and resorcin with advantage. A warm and moist climate seemed to have the best effect.

Pruritus.—Dr. E. B. Bronson, of New York, in an argumentative paper on this subject, gave the following conclusions: 1. That there was a sense of contact independent of the sense of pselaphesis. 2. That this sense of contact was the sense disturbed in pruritus. 3. That it concerned primarily simple cutaneous nerves or nerve-endings situated superficially and probably in the epidermis. 4. That the disturbance in pruritus was of the nature of a dysæsthesia due to accumulated or obstructed nerve excitation with imperfect conduction of the generated force into correlated forms of nerve energy. 5. That scratching relieved itching by directing the excitation into freer channels of sensation, sometimes, especially when severe, substituting either painful or voluptuous sensations for the pruritus. 6. That the voluptuous sensations which might attend pruritus were a manifestation of a generalized aphrodisiac sense, representing a phase of common sensation that had its source in the sense of contact.

Cutaneous Tuberculosis.—Dr. J. T. Bowen, of Boston, read a paper containing the histories of a number of cases of cutaneous tuberculosis, together with histological studies, and expressed the view, also entertained by Dr. White, through whose courtesy some of the cases had been seen, that several affections of the skin not yet recognized as inoculable would be proved to be so, and their relation to tuberculosis be demonstrated.

The Treatment of Dermatitis Herpetiformis.—Dr. L. A. Duhring, of Philadelphia, said that the several papers published by him on dermatitis herpetiformis during the past five years had contained no reference to treatment. Having now reported ten or twelve cases, it seemed appropriate to speak of the treatment of this exceedingly rebellious disease. Each group of cases based on the ætiological factors at work required special handling. A speedy cure was not to be looked for. It must be remembered that the disease, as a rule, was multiform in character, and the several varieties naturally called for different formulæ, especially as to the strength of the remedy. His experience had been that milder remedies were called for in the erythematous than in the vesicular and bullous forms. A difficulty to contend with was the tendency of the disease to repeat itself, a new crop coming out before the older ones had disappeared. Almost all his cases had been chronic and had previously undergone all manner of treatment. He had long since arrived at the conclusion that most benefit was to be derived from stimulating applications, especially those which acted as revulsives—tar, carbolic acid, sulphur, thymol, ichthyol, resorcin, etc. That which had proved of greatest value in his hands had been sulphur ointment, two drachms to the ounce, applied by thorough and long rubbing so as to make a positive impression upon the skin, causing, as it were, local shock. Special emphasis was placed upon the manner of making the application. Internal remedies had proved of little avail in most cases.

Atrophia Maculosa et Striata following Typhoid Fever.—Dr. F. J. Shepherd, of Montreal, presented the history of a case, illustrated by photographs. It had occurred in a boy of fifteen years, brought to the hospital with typhoid fever. During the course of the disease he was delirious and had epileptic attacks. Macular lines formed, extending across the patellæ and around the anterior aspect of the thigh to near the middle, some being several inches long. They were of a reddish color and afterward became paler; they were not distinctly shiny and were grooved. The interesting point in the case was the occurrence of the atrophic lines in a boy during acute fever. He did not think their presence could be accounted for, as they were in œdematous subjects, by stretching. There seemed to be a nerve element in the causation.

Immigrant Dermatoses.—Dr. J. C. White, of Boston, read a paper with this title. It included an account of the affections of the skin induced by life on shipboard, those induced after arrival by conditions not existing previously, and those seen in other countries, but not in native Americans. Conditions on shipboard tending to induce skin affections were mental depression on leaving home, seasickness, filth and foul air, constipation, inability to take exercise, and contact with others having contagious disease. It was not uncommon for young persons to come a week or ten days after landing with an urticarial, bullous, or eczematous eruption. Vaccination on shipboard

not infrequently left a local sore of wider area than usual, due perhaps to a depressed state of health and the fact that the patient had not been revaccinated since childhood. Under the second head the causes were new agencies not existing at home, among them being, perhaps, mosquitoes. Under the third head, imported affections, the most common was scabies; among others was that rare affection, melanosis lenticularis progressiva, none of the cases here, as far as he knew, being in native American stock. Prurigo also might be regarded as an imported disease, and was seen scarcely elsewhere than in cities with a large foreign population, like New York and Chicago. The relative prevalence of vegetable parasitic affections among us was likely to be largely influenced by immigration. Tinea favosa, tinea trichophytina, and tinea versicolor were commoner in countries whence we received many immigrants than they were here. The same was true of tubercular affections of the skin, and he was disposed to regard lupus, scrofulodermia, scrofulous gummata, tuberculosis verrucosa, etc., as closely allied affections. Leprosy was another imported disease, coming from many sources. In conclusion, the author suggested the propriety of memorializing the National Government with regard to carrying out the following measures: 1. To cleanse all immigrants of animal parasites on their landing by treatment of the person and clothing. 2. To retain in quarantine all immigrants with other contagious diseases, including venereal affections, a sufficient time for treatment. 3. To return to their homes all persons affected with such contagious diseases as it was impracticable to treat in such manner, such as leprosy, tuberculosis, and advanced syphilis. 4. To provide for efficient medical inspection at foreign ports of emigration, with the power of arresting the transfer of dangerous diseases to this country.

A Case of Second Infection with Syphilis and a Case of Syphilitic Infection in a Person Hereditarily Syphilitic.—Dr. Taylor gave detailed histories of the two cases which had come under his observation within a year. The first was in a sickly-looking woman, aged thirty-eight, who entered Charity Hospital in January last. Eleven years ago she had syphilis, having had hard swelling of the external genitals, enlargement of the glands, an eruption shortly afterward all over the body, and headache at night. In the second year she had rheumatoid pains and mucous patches, and in the third year serpiginous syphilides, etc. She married and gave birth to two weakly children, which soon died. Her husband having died, she again lapsed in virtue, and came to Charity Hospital in January last, broken down in health. There were typical miliary syphilides scattered over nearly the entire surface. All the ganglia were decidedly enlarged. There were mucous patches of the tongue and mouth and evidences of alopecia. She suffered with pain in the joints, worse at night. The second attack was much more severe than the first. She was now improving under mercurial treatment.

The second case was one of acquired syphilis in a person hereditarily syphilitic. The woman came to him first in 1879, aged nineteen, when he treated her for a destructive syphilitic sore on the face, arising from hereditary syphilis, a clear history of which was afterward given him by her mother, who had acquired syphilis three months before the child's birth. The child had a rash, condylomata, and snuffles, and was weakly. Five years after his patient's first visit, in 1885, she returned, and had then macular roseola and scaling syphilides all over the body, condylomata of the genitals, mucous patches of the pharynx, etc. The infection began in the right labium, and was contracted from the husband. The glands were all enlarged, and there was alopecia. She had since been cured.

Electrolysis in the Treatment of Lupus Vulgaris.—Dr. G. T. Jackson, of New York, in a paper on this subject, said the advantages that electrolysis offered in the treatment of lupus vulgaris, compared with other and older measures, were as follows: 1. It was comparatively painless, and there was no need of an anæsthetic. 2. There was not the slightest loss of blood, and thus there was no dread of a surgical operation. 3. The patient was not kept a moment from his regular business, there was no deformity caused by the treatment, and there was no after-treatment or application to mar the appearance. He was also spared the discomfort of a swollen face and eyes, the ordinary attendant on the arsenical or pyrogallic-acid treatment. 4. The treatment went to the root of the disease, with far more exactness and less damage to the surrounding skin than any other caustic or surgical method. 5. The scar left was smooth and not unsightly. 6. The result obtained was as good as by any previous method, if not better.

Plica.—Dr. H. W. Stelwagon, of Philadelphia, showed photographs from a case that he had seen a few months before. He was not sure that plica was the right name for it. An Irishwoman who had come to be treated for acne called his attention to a lock of hair, as thick as one's thumb, springing from the middle of the occipital region, closely matted together, and falling as low as the ankles, terminating in a brush-like end. It was not sticky and had begun to grow four years before, without apparent cause. The rest of the hair fell over the shoulders and was not matted. There was no uncleanliness.

The Treatment of Erysipelas.—Dr. C. W. Allen, of New York, based a paper on the results of treatment during the past two years of 419 cases in the hospitals on Blackwell's Island, not under his care, and 47 cases in his own practice during the same time. The author thought that, although tending to pursue a definite and usually favorable course, the disease could be checked in its progress by treatment. Among the applications that had been used were boric acid, iodine, resorcin, bicarbonate of sodium, ichthyol, collodion, and aristol, and scarification with the knife and the application of plaster strips had been used. He was disposed to think favorably of scarification and adhesive plaster, separately or together in the same case, but had tried them in only about two cases.

Notes on Pilocarpine in Dermatology.—Dr. H. G. Klotz, of New York, gave a review of the history of pilocarpine in dermatology, and said it had not met with the acceptance that might have been expected if its other therapeutic virtues had been at all proportionate to its diaphoretic qualities. He had employed it in a few cases, including eczema, pruritus of the anus, and affections with dryness and irritation. The result had been such as to encourage him to give it a further trial. It might be given internally or by hypodermic injection, in small doses, long continued. A tenth of a grain was likely to prove sufficient to keep the skin moist.

Aristol.—Dr. Allen read a paper giving the results of his experience with this new remedy, and summed up with the statement that it seemed to possess valuable cicatrizing, granulating, and stimulating qualities, was void of the objectionable odor of iodoform, and seemed valuable in certain dermatologica cases.

Results of the Treatment of Dermatological Cases with Sulphur Water at Richfield Springs.—Dr. C. C. Ransom, the physician in charge of the new bathing establishment, by invitation, gave the results of treatment of dermatological cases there. Since the new bath had been completed, during the summer twenty-two cases had been treated, including nine of eczema, one of psoriasis, four of seborrhœa, one of pruritus, and two of urticaria. There had been marked improvement in nearly all these cases, and in some a cure. The baths were of a temperature usually of from 95° to 106° F., lasting from seven to fi

teen minutes. A longer stay in the sulphur bath had a depressing effect, lasting some hours.

The meeting adopted resolutions expressing appreciation of the very extensive and complete equipment for water treatment established by Mr. Proctor at the Springs.

Special Articles.

LETTERS TO MY HOUSE PHYSICIANS.

By WILLIAM OSLER, M. D.,
BALTIMORE.

Letter V.

HEIDELBERG AND STRASSBURG.

Dear H.: We stayed a day at Frankfort, as I was anxious to visit Weigert, and my colleague wished to see Edinger about methods of brain preparation. After Cohnheim's death, in 1884, Weigert left Leipsic and accepted the charge of the Laboratory of the Senckenbergischen Stifts (a hospital founded in 1763 by Dr. Senckenberg), a position which has been occupied by several most distinguished German professors, notably Soemmerring, the anatomist. It would be difficult to mention a histologist to whom the profession is more indebted than to Professor Weigert, as by the introduction of the aniline stains he has revolutionized the study of bacteriology, while his special methods have been of incalculable service in normal and pathological histology. We found him busy at a new stain for neuroglia, which will show the connective-tissue framework as plainly as his well-known method does the medullated nerve fibers. It is not yet perfected, but he demonstrated specimens of extraordinary beauty, showing the rich plexus of fibers in the gray matter of the cord. The stain will be most useful in determining slight grades of sclerosis, as it picks out unerringly every neuroglia element. The method is not sufficiently matured to warrant publication, and in this respect Weigert exercises a most commendable caution. He will work month after month, early and late, until every possible modification has been tried and every contingency met before the plan is finally approved and announced. I was in the laboratory at Leipsic when he was working at his celebrated nerve stain, and the patient thoroughness with which day by day the method was tested, then improved, and at last completed, was a valuable lesson, and showed a spirit which all of us might emulate. Another important stain for elastic fibers will also be ready soon, which brings out the most delicate fibrils with the greatest distinctness, such, for example, as a set of longitudinally arranged filaments just beneath the endothelial lining of the arteries. There are places in the laboratory for six or eight special students, and, with so genial a teacher and so thorough a master of histological methods, it is not surprising to hear that the applicants are numerous.

Edinger was extremely kind in showing us his collection of brain sections, which is particularly rich in those of the frog and turtle; but he is also, as you know from his excellent little work, a diligent student of human cerebral anatomy. It is remarkable that a man engaged in active practice can spare time for these studies, but I suppose he has learned the secret of the value of odd minutes and spare hours. He had recently received from Dr. Ramon y Cajal, the Spanish histologist, a specimen illustrating his remarkable discovery of the branching of the nerve fibers in the spinal cord. The sections prepared by Golgi's well-known method showed collateral branches from the axis-cylinder process, some of which form a dense plexus about the ganglion cell.

At Heidelberg we found the outside attractions of this ideal university town too strong for much medical visiting. Of course we saw Professor Erb, whose extensive writings on the nervous system are as highly appreciated in America as in Europe, and in his morning rounds we found a rich material in well-arranged wards. For many years the clinic here has been particularly strong in the department of neurology, the result no doubt of the impetus given by the master mind of Friedreich; and Erb and Franz Schultze, now professor at Bonn, have worthily maintained its reputation. Naturally there were cases of Friedreich's ataxia and of Erb's dystrophia muscularis progressiva on exhibition. A short time before our visit, Horsley had come over from London to operate on a son of the late Professor Chelius, who had paraplegia, the result of an injury in the hunting field. Erb stated that it was too soon to say how far the operation had been successful. One gets the impression that everything works smoothly at the medical clinic, and I can well understand how it is that the young men who have been here speak very warmly of it as a most agreeable place for post-graduate study.

The pathological laboratory has long been a favorite resort for American students, and we are indebted to Professor Arnold for a very pleasant hour in its various departments. He is one of the most expert histologists in Europe, and, having been for years familiar with his numerous and elaborate contributions in Virchow's *Archiv*, I was particularly glad to have an opportunity of meeting him.

At the biological laboratory we saw Professor Butschli, perhaps the greatest living authority on the protozoa. He talked most interestingly about the pathogenic sporozoa and the hæmatozoa of birds and fishes. He had lately seen in Italy the malarial organisms, and it was gratifying to hear that, although he had had grave doubts at first, he had been convinced of their parasitic nature. The problem of the life history of these parasites outside the body could be best attacked in a biological laboratory, under the direction of a man thoroughly acquainted with the conditions of growth of the protozoa. By the way, a knowledge of these organisms is gradually reaching this country. Professor Rosenbach, of Breslau, was with us at the hospital last autumn for a day or two, and we showed him the various forms, but he did not seem at all convinced. He has recently, however, had opportunities of studying cases, and has published a paper expressing his concurrence with Laveran's views. Quincke, too, of Kiel, one of the highest authorities on the blood, has within the past few weeks described the parasites in several cases. As we strolled along the Castle Road we inquired the nature of the large building close to the hotel, and were told that it was Professor Schweninger's "Kur-Anstalt." You know, I dare say, the story of the Munich Docent who became Bismarck's physician, and was foisted into the Berlin faculty as professor of dermatology. Certainly he has shown great wisdom in the choice of a locality in which to make the fat leau and the lean fat. We were shown through the place by the resident physician, and, so far as we could gather, the remedial agents employed were the old-time favorites of Asclepiades—regimen, exercise, baths, and friction. The professor appears once a week and directs the treatment.

With only three or four days to spend at Heidelberg, we escaped quickly from hospitals and laboratories, and in delightful mountain walks, at the castle, and, must it be said, at "Zum Perkeo," we tried to recognize, if not to feel, the romance which fills every nook and corner of this place. A month's sojourn in this earthly paradise would be the thing for the tired, patient-worn doctor who goes to Europe for rest. Resisting the devil, which drives so many of us from Dan to Beersheba, racketing about in a restless holiday, let him unpack his trunk at the Castle Hotel and spend his days on the mountains, and he will find peace of mind and rest of body.

With the exception, perhaps, of certain of the new laboratories at Berlin, the university buildings at Strassburg are the finest in Germany, having been paid for by the Imperial Government, which still furnishes the means of support. They are on a most magnificent scale, and comprise on the east side of the town the central university building and the chemical, physical, geological, and botanical laboratories, while on the south side near the old City Hospital are the various institutes devoted to physiology, physiological chemistry, pathology, anatomy, and pharmacology, and the clinic for nervous and mental diseases. Together the latter form a most imposing group, just within the fortification wall, with the buildings not too close to spoil the architectural effects and each within easy access of the other, so that no time is lost by the student.

The medical clinic is still in the City Hospital, but new accommodations have been promised and are much needed, as the old building looks like a survival from the tenth century. Professor Naunyn, who

succeeded Kussmaul about eighteen months ago, is a representative German clinician, thoroughly scientific, thoroughly practical, an ardent worker, an admirable teacher, and a most genial colleague. Like his teacher, Frerichs, he is an able chemist and a good experimenter. He has had a varied professorial career, having occupied in succession the chair of medicine at Dorpat, Bern, and Königsberg. The method of teaching is practically the same as at other German schools, but on two mornings of the week the class is taken into the wards and the students are drilled at the bedside. We were present at one of these demonstrations, which was perfect of its kind, but, as is so often the case, there were too many men clustering about the patient. Professor Naunyn then took us through all the wards and pointed out several cases of special interest, among them one of Virchow's hyperplasia of the circulatory system in a young girl, and another of hepatic intermittent fever. In the chemical laboratory we found in progress experiments on the brains of birds, conducted by one of the assistants, and researches on the chemistry of gall-stones and the pathology of diabetes. The collection of gall-stones was very fine, and the professor has recently demonstrated certain canaliculi through which the cholesterin reaches the central parts.

At the pathological laboratory Professor von Recklinghausen was just about to lecture, and we heard a very concise yet clear explanation of the pathology of emphysema and bronchiectasis. I am sure many teachers would have spent three lectures in covering the same ground; only a few typical, perfectly illustrative specimens were shown. The demonstration courses, the daily sections, the classes in pathological histology, and the private work are personally conducted by the director, who seems to leave very little to the assistants. This is one reason, perhaps, of the popularity of this laboratory with foreigners. It was rather surprising to see the students cutting sections in the old free-hand method with the razor, but the professor insists that often a better idea of the changes in a tissue can be had from a moderately thick than from an extremely thin section. A point of much greater value was the care with which fresh specimens were examined either by section or by teasing. The uniform kindness and the untiring patience with which Professor von Recklinghausen treats the young men who work under him finds its proper reward in the affection with which he is regarded by them.

An illustration of the catholic character of the mind of the great master, Virchow, is afforded by the fact that four of the greatest physiological chemists of Germany grew up under his inspiration—Hoppe-Seyler, Kühne, Liebreich, and Salkowski. The Physiological Chemistry Institute, presided over by the first mentioned of these men, is by far the most complete in the world, and has been planned and equipped regardless of expense. There were few men I was more curious to see than Hoppe-Seyler. In the first place, as our respect for a subject is oftentimes in direct proportion to our ignorance, I had never, in spite of a period of study with Salkowski, outgrown a sense of the deepest reverence for physiological chemistry—a reverence which was increased, if possible, by an acquaintance with the works of the Strassburg professor; and then my assistant and successor at McGill, Dr. Wesley Mills, during a prolonged stay "learned his great language, caught his clear accents," and made me feel that as a man and as a worker Hoppe-Seyler was in some ways exceptional. We found a class of about thirty students listening to a lecture on gastric digestion, the steps of which were very skillfully shown. The greater part of the time was occupied with a discussion of the nature and varieties of peptone. It was gratifying to hear the name of Dr. Chittenden, of Yale, so frequently mentioned, on whose work the professor seemed to place a very high estimate. Hoppe-Seyler is an older man than I expected to find, but he is vigorous and active and has a very friendly and attractive manner. I knew that the institute was a large one, but the great extent and the completeness in every detail were a revelation. The advantages for research work are so favorable that the special laboratory is always full of men from all parts of the world. The students can follow practically in the general laboratory the subject upon which the professor is lecturing, but it is to be seen at a glance that the prime object of the institution is investigation.

Professor Schmiedeberg very kindly showed us his Pharmacological Institute, which is also, I believe, without parallel among similar institutions. As you will find an admirable description by Dr. Sibley, with illustrations, of the chief Strassburg laboratories in the early numbers of the *British Medical Journal* of this year, I will spare you the account of physiological and anatomical institutes. In the former, besides Professor Goltz's dogs in a more or less brainless condition, the work of Professor Ewald interested us intensely as an illustration of micro-chirurgy. In operating on the semicircular canals of pigeons, in order to obviate all unnecessary laceration and bleeding, the dissection, with the strictest antiseptic precautions, was made under a specially devised low-power microscope, and the vein, not so big as the finest thread, which runs over the canal, was included between two ligatures and cut. He had the tiniest little instruments, and every detail was carried out in miniature. I must mention the extreme kindness of Professor Schwalbe, with whom we spent the last, as in many ways it was our best, day in Germany.

Now, as you are in part a Teuton, it may interest you to know the general impression one gets of the professional work over here. I should say that the characteristic which stands out in bold relief in German scientific life is the paramount importance of knowledge for its own sake. To know certain things thoroughly and to contribute to an increase in our knowledge of them seems to satisfy the ambition of many of the best minds. The presence in every medical center of a class of men devoted to scientific work gives a totally different aspect to professional aspirations. While with us—and in England—the young man may start with an ardent desire to devote his life to science, he is soon dragged into the mill of practice, and at forty years of age the "guinea stamp" is on all his work. His aspirations and his early years of sacrifice have done him good, but we are the losers and we miss sadly the leaven which such a class would bring into our professional life. We need men like Joseph Leidy and the late John C. Dalton, who, with us yet not of us, can look at problems apart from practice and pecuniary considerations.

I have said much in my letters of splendid laboratories and costly institutes, but to stand agape before the magnificent structures which adorn so many university towns of Germany and to wonder how many millions of marks they cost and how they ever could be paid for, is the sort of admiration which Caliban yielded to Prospero. Men will pay dear for what they prize dearly, and the true homage must be given to the spirit which makes this vast expenditure a necessity. To that *Geist* the entire world to-day stands debtor, as over every department of practical knowledge has it silently brooded, often unrecognized, sometimes when recognized not thanked.

The universities of Germany are her chief glory, and the greatest boon she can give to us in the New World is to return our young men infected with the spirit of earnestness and with the love of thoroughness which characterize the work done in them.

Book Notices.

L'intoxication chronique par la morphine et ses diverses formes. Par le Dr. L. R. Regnier, ancien interne en médecine des hôpitaux de Paris. Paris: E. Lecrosnier et Babé, 1890. Pp. 5 to 171. [Publications du *Progrès médical.*]

In this interesting monograph the author concludes that the prolonged use of opium or its alkaloids produces a chronic intoxication, morphinism. The intoxication may be due to inevitable therapeutic necessity or to a pathological desire originating from the temperament of the individual. The *morphinisé* is distinguished by the absence of psycho-sensorial phenomena, and by the absence of grave symptoms when the drug is stopped. The *morphinomaniac* is distinguished by the almost constant presence of a nervous state, hereditary or acquired by disease; or by physical or psychical symptoms of degeneration, indicated by a mixture of psycho-sensorial phenomena with manifestations usual in ordinary morphine intoxica-

tion. Morphine intoxication rarely produces complete loss of responsibility, and it does not cause irresistible impulses; the latter, however, are present in a morphinomaniac, especially when deprived of the drug.

Morphinomaniacs should be confined in asylums until they are cured, if such a result is possible.

The author has collected a large number of illustrative cases, and completes his work with a copious bibliography.

Die Untersuchung der hinteren Larynxwand. Von Dr. Gustav Killian, Privatdocent für Laryngologie und Rhinologie in Freiburg i. Breisgau. Mit 40 Abbildungen in Texte. Jena: Gustav Fischer, 1890. Pp. 77.

The author enters into an interesting theoretical consideration of the methods of inspecting the posterior wall of the larynx, proving by trigonometrical calculations the proper angle for the mirror and attitude of the head in order to admit of an inspection of that region. The desired end can be obtained by two methods: one with the head thrown backward and a mirror (holding the epiglottis out of the way) reflecting the posterior surface of the larynx on a second mirror held against the velum palati; the second, with the patient standing and holding the head forward with the face downward, and the physician kneeling to obtain the reflection of the posterior wall in a mirror held against the velum. A number of cases are cited in evidence of the necessity of inspecting the posterior as well as the anterior laryngeal surface; and they demonstrate the practical applicability of the methods described.

Rheumatism and Gout. By F. Leroy Satterlee, M. D, Ph. D., Professor of Chemistry, Materia Medica, and Therapeutics in the New York College of Dentistry, etc. Detroit: George S. Davis, 1890. Pp. 83. [The Physician's Leisure Library.]

This excellent monograph, while containing little that is new, is eminently practical and presents the subject in a concise and interesting manner. It deals chiefly with treatment. The author, holding firmly the uric-acid theory of causation, relies almost exclusively upon diet, cholagogues, and alkalies. His sweeping condemnation of the salicylates in rheumatism and of colchicum in gout is to be regretted.

A particular merit of the book is its literary style.

Diabetes Mellitus and Insipidus. By Andrew H. Smith, M. D., Professor of Clinical Medicine and Therapeutics at the New York Post-graduate Medical School and Hospital, etc. Detroit: George S. Davis, 1890. Pp. 74.

The author states that the object of this little work is not to compress into the fewest possible words all that is known or surmised in regard to diabetes, but to give the points that will most interest those who have to manage cases of this disease. Undetermined questions are not discussed. Prevention, dietetic treatment, the use of drugs, and hygienic measures are carefully considered, and the best methods indicated. As the outcome of experience and skill, the brochure recommends itself alike to the general and to the special practitioner.

Some Fallacies concerning Syphilis. By E. L. Keyes, M. D., etc. Detroit: George S. Davis, 1890. Pp. vi–71. [The Physician's Leisure Library.]

This monograph is so clearly written that one is in no sense left in doubt as to the writer's opinions. The mercurial treatment is well supported, and, with records of more than forty years at his disposal, Dr. Keyes should be able to speak authoritatively of that subject.

Practical Electricity in Medicine and Surgery. By G. A. Liebig, Jr., Ph. D., Assistant in Electricity, Johns Hopkins University, etc., and George H. Rohé, M. D., Professor of Obstetrics and Hygiene, College of Physicians and Surgeons, Baltimore, etc. Profusely illustrated. Philadelphia and London: F. A. Davis, 1890. Pp. viii-3 to 383. [Price, $2.]

This is a thoroughly useful book, with the exception, perhaps, of its superabundance of formulæ, which make the first part a trifle too technical for the average practitioner. The science of electrical forces, the various forms of electrical and magnetic apparatus available for medical and surgical work, the best methods of caring for batteries, the effects of electric currents upon tissues and organs of the body in health and disease, the general therapeutic effects of electricity, modes of application—especially in gynæcology, diseases of the skin, and diseases of the male genito-urinary organs—are carefully considered and practical suggestions are formulated. Whatever brings into greater knowledge electricity as a remedial agent must be received with gratitude. The work under consideration aids in the accomplishment of this purpose.

Transactions of the American Orthopædic Association. Third Session, held at Boston, Mass., September 17, 18, and 19, 1889. Volume II.

In this volume the principal subjects in orthopædic surgery are dealt with by the leading men of the country. Hip disease is given special consideration, both in original articles and in the discussions.

The volume will be a valuable addition to a surgical library.

New Inventions, etc.

A FEW NEW CUTTING INSTRUMENTS FOR NASAL WORK.

By A. T. Veeder, M. D.,
Schenectady, N. Y.

Having recently had made by Snowden, of Philadelphia, and remodeled by Messrs. Tiemann & Co., of New York, several nasal cutting instruments or forceps, I give below illustrations of the same.

The first—somewhat of the order of a septal punch—I have used with great comfort, quickly making a passage through the nose where there was partial opening or complete occlusion of the nares by reason of bridges of bone or bone and cartilage extending all the way across, producing either permanent pressure against or indentation of the turbinated bodies.

This cutting punch or forceps, the edge of the cutting part of whic

is of well-tempered steel, in operating is pressed on the reverse blade of the instrument, which is flat and faced with a thin plate of German silver so that the edge may not be quickly dulled, and yet not so quickly indented as the softer metal copper might be. It cuts through bone easily in a very few seconds, and does away, in my hands, with a good deal of protracted and troublesome sawing, leaving separated surfaces which heal quickly and smoothly. Several widths and sizes are needed, inasmuch as all noses are not of the same proportion.

The ends which enter the nose should be two inches and a half in length from the point where the two blades are connected. Also the instruments, as will be observed in the cuts, have a curved and angular form, which allows the eye to see straight into the nose while they are introduced, and the reopening spring gives convenient and quick movement.

The other two are simply right and left cutting forceps, having one cutting edge or blade to press flat against the septum, bringing it down on the smooth face of the opposite blade, which has also a thin plate of German silver to receive the pressure of the cutting edge.

These two instruments are designed for the quick removal of small ecchondroses or exostoses which present the shelf-like form.

September 9, 1890.

Miscellany.

Mortality in Cities in the United States.—The following table represents the mortality in the cities named, as reported to Dr. John B. Hamilton, Surgeon-General of the Marine-Hospital Service, and published in the Abstract of Sanitary Reports for September 12th:

CITIES.	Week ending—	Estimated population.	Total deaths from all causes.	DEATHS FROM—									
				Cholera.	Yellow fever.	Small-pox.	Varioloid.	Varicella.	Typhus fever.	Enteric fever.	Scarlet fever.	Diphtheria.	Measles.	Whooping-cough.

Spirometry.—"M. Joal, of Mont Dore, has made a number of observations in spirometry that lead him to the conclusion that many nasal and pharyngeal affections produce a distinct diminution in the capacity of the lungs. Thus in cases where hypertrophic rhinitis, adenoid tumors of the naso-pharynx, chronic coryza, etc., have been cured the capacity of the lungs, as measured by the spirometer, is frequently increased by a quarter, and occasionally even doubled. M. Joal has frequently found that public singers, when they complain of fatigue of the voice or of diminution in its power or range, are suffering from some, perhaps quite unsuspected, trouble in the nose or pharynx, and that if this is cured the voice recovers itself completely. He suggests that professional singers should know their own respiratory capacity, and that this should be occasionally tested, so that any diminution may serve to give a warning of possible mischief in the nose or pharynx, which, if attended to in time, may be met by appropriate treatment."—*Lancet.*

ANSWERS TO CORRESPONDENTS.

No. 330.—There is no advantage in stitching the wall of the bladder to the skin.

No. 331.—The excess of acid in the tincture of iron is neutralized by the sodium tartrate contained in the preparation, and the resulting mixture is said to be tasteless and the systemic action of the iron to be facilitated rather than impaired.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Original Communications.

A CASE OF BRAIN SURGERY
AND ITS RELATIONS TO CEREBRAL LOCALIZATION.

BY WILLIAM A. HAMMOND, M. D.,
WASHINGTON, D. C.

Miss G. entered my Sanitarium July 20, 1890, suffering from an old left hemiplegia, epileptic convulsions, mental deterioration, and occasional paroxysms of maniacal excitement. The clinical history taken by Dr. E. L. Tompkins, the resident physician, soon after her admission, is as follows:

Nineteen years of age. Father, Italian: mother, American. Residence, Marshall, Texas. Family history good. Father and mother healthy. No history of syphilis. The patient was born healthy and normal. Rather difficult labor, but no forceps was used. First sickness occurred when the infant was five weeks old and consisted of cholera infantum. During this attack she became rigid, arms and legs contracted and flexed, more pronounced on the left side than on the right. Right side recovered, but the left side remained more or less contracted. Shortly after this she had aural catarrh on the left side and a very offensive discharge. From this she apparently entirely recovered without impairment of hearing. During the period of teething she had "spasms" accompanied with frothing at the mouth. She had no more of these attacks until she was about five years old, when, upon one occasion while sitting quietly in a chair, she was seized with a convulsion attended with unconsciousness, frothing at the mouth, and a deviation of the eyes toward the left side. She had no other seizures after that for a year, when another ensued similar to the last. After that the convulsions became more frequent, occurring at intervals of from one to six months. They generally began with a rigor down the back, cold hands and feet, and trembling of the left side. It was impossible to get her warm until after the attack. During this period she was under no special treatment except during a seizure, when a physician would be called in. Measures, however, were adopted for rectifying the contractures. These consisted of electricity (faradism), massage, and tenotomies, which did not improve matters. When she was about ten years of age the seizures assumed a different form; there were nausea and vomiting, and again they were ushered in with a period of great excitement, during which she would sing and shout loudly. As she was very pious, everything of a religious nature would cause great mental disturbance. For the last four years she has been aware, for sometimes as long as twelve hours, that an attack was about to occur, as she would be pale, especially around the eyes, "humps" would make their appearance on the face, and there was more or less vertigo with mental confusion. After the occurrence of a paroxysm her mind would clear up and she would feel much better. Sometimes there was loss of consciousness and again not, but she was always greatly frightened before and for some time after the seizure. Began menstruating at twelve years of age, each period lasting four or five days; was regular for about a year and then ceased menstruating for two years; since then has been irregular. Epileptic convulsions much more severe at the time menstruation ought to have appeared. Left hand apparently stopped growing some six years ago, as also did the left foot. For the last five years she has exhibited marked symptoms of mental derangement, committing many singular actions and being very silly and weak-minded. Has been to school for a short time, but would have headache and fits when studying for any considerable period. At times could read very well, at other times would seem unable to read. Her memory has been apparently good, especially in regard to matters concerning herself. Has had none of the ordinary children's diseases except measles. For the last six months her mental symptoms have been much more intense, singing loudly on improper occasions, and making a great deal of noise, also using very bad language; religion and money being subjects that would especially disturb her.

Examining her on her admission to the Sanitarium, I found that both mind and body were undeveloped. Her expression indicated a state of decided imbecility, though at times in the course of my conversation with her she exhibited considerable sharpness. The left hand was in a state of extreme flexure and was permanently contracted, although several of the flexor muscles had been divided by a surgical operation. The elbow also was in a state of flexion, though not fixedly contracted, there being some slight degree of action. The muscles about the shoulder joint, especially the deltoid, were paralyzed and atrophied. The whole extremity was in a state of atrophy, and there was not a muscle that was not more or less paralyzed.

The left lower extremity was in a similar state, though not anything like to the same extent. The muscles of the hip and thigh were in tolerably good condition. The extensors of the foot, especially the *tibialis anticus* and peroneal muscles, were possessed of very slight contractile power. The *gastrocnemius* and *solæus* muscles were in a state of contraction, although the *tendo Achillis* had been divided several times. All of the paralyzed muscles of both the upper and lower extremity exhibited diminished electric excitability.

The left side of the face was much less mobile than the right. There was no permanent strabismus, but occasionally there had been double vision; the pupils were equal and reacted well to light and to near and far vision. The tongue was apparently mobile, but when protruded deviated strongly to the left, the paralyzed side. The speech was somewhat indistinct, the lingual sounds were imperfectly formed, and there appeared to be a deficient adeptness in using the tongue for purposes of articulation. Occasionally there had been difficulty in swallowing. The eyesight was not materially affected, but upon ophthalmoscopic examination I found a venous congestion of both retinæ and chorioids with somewhat whitened discs. The hearing was not impaired, though, as stated in the clinical history, there had been in early life profuse otorrhœa. The patient, although nineteen years of age, was physically undeveloped; the skull was unsymmetrical, the right side being distinctly smaller than the left. Latterly the epileptic convulsions had become more frequent. Sometimes the muscular spasms were confined to the left side of the face, left arm and leg, but again, though originating in these parts, they became general. There was always loss of consciousness.

Within the last four or five months the convulsive seizures had not only been more frequent, but she had become subject to paroxysms of intense excitement, during which she raved incoherently and was very abusive to those about her, using profane and filthy language. On any attempt being made to restrain her she fought with her arms, legs, and teeth in a manner which can only be described as ferocious. Even a few words of reproof were sufficient at times to bring on these attacks, which in all essential respects were not different from those of acute mania.

I gave it as my opinion that she was suffering from a morbid growth of some kind, involving the left parietal lobe and part of the frontal lobe, especially the ascending parietal convolution and the ascending frontal convolution. I expressed my willingness to undertake an operation for the patient's relief. I

explained to the parents that the prospect of cure was very remote, but that I thought there was nothing else that offered the slightest hope of alleviation; that without such operation the child would become permanently insane, and would probably die in a few months; and that it was quite probable that during one of the paroxysms of maniacal excitement to which she was subject she might commit some act of extreme violence, even to the extent of homicide, and that there was some hope that an operation, if based upon a correct diagnosis, would result in the cure of the epilepsy and of the paroxysms of insanity. The paralysis I regarded as absolutely irremediable. They expressed their desire that the operation should be performed, and the patient herself, to whom the matter was as fully explained as was possible, was equally anxious to have anything done that afforded her even the slightest prospect of relief.

Accordingly, on the morning of July 23d, at eleven o'clock, assisted by Dr. Tompkins, the resident physician of the Sanitarium, and Dr. Pedigo, of Roanoke, Va., I began the operation. The patient was first completely anæsthetized and the scalp covering the parietal and lateral frontal portions of the skull shaved. The first point was to determine by measurements the exact situation of the fissure of Rolando. There are many methods of doing this, some of them exceedingly troublesome and complex, without thereby being of any greater practical adaptability. The fissure of Rolando is very rarely in exactly the same relative position in any two brains, and those processes for determining its location and direction by external indications, involving the measurement of angles to a fraction of a degree and lines to the fraction of a millimetre, are pedantic and useless. It has always appeared to me, and I have verified it by many observations, that the method of Reid* is sufficiently exact for all practical purposes, and that the fissure of

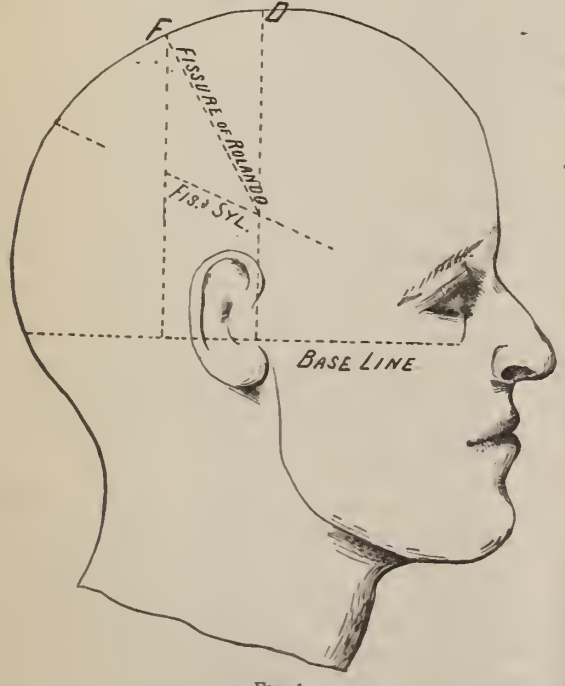

Fig. 1.

Rolando does not, in one case out of a hundred, lie as much as the eighth of an inch anteriorly or posteriorly of the line drawn according to his method. A surgeon, therefore, has simply to proceed, guided by the directions he has given, and, placing the center-pin of the trephine on the line obtained, he will reach the fissure of Rolando as often as he may make the attempt. In the accompanying figure, taken from Reid's paper, his process is clearly shown. It is described as follows: A base line is drawn from the inferior margin of the orbit through the external auditory meatus. Two perpendiculars, F and D, are then drawn; the one, D, is raised from the depression in front of the external auditory meatus, the other, F, from the posterior border of the mastoid process. A line drawn from a point an inch and a quarter behind the external angular process of the frontal bone to another three quarters of an inch below the most prominent part of the parietal eminence will indicate the position of the fissure of Sylvius. Now let a line be drawn from the upper extremity of the perpendicular F to the point on D where it is intersected by the line indicating the fissure of Sylvius, and we have the position of the fissure of Rolando.

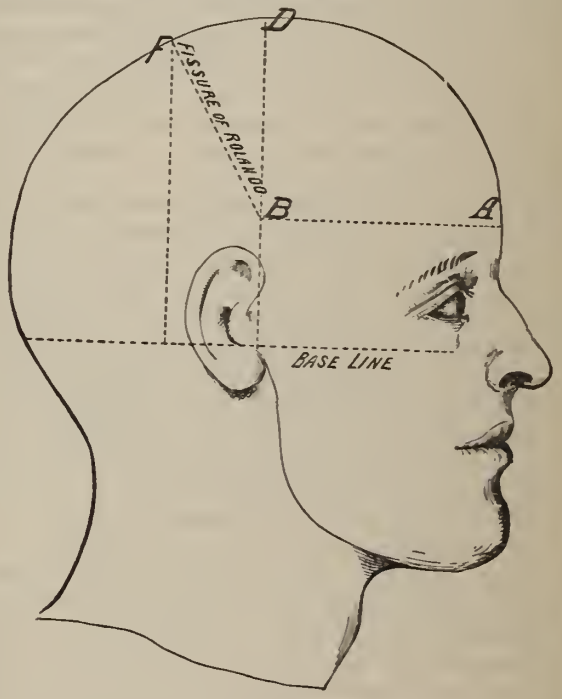

Fig. 2.

I have ascertained from repeated measurements that this process can be greatly simplified as shown in Fig. 2. The base line and the two perpendiculars are the same as in Reid's figure, but a line, A, B, is drawn parallel to the base line from a point on the forehead an inch above the supra-orbital foramen to the perpendicular, D. Now a diagonal drawn from the superior extremity of the perpendicular, F, to the point of intersection of the line, A, B, with the perpendicular, D, will indicate the course of the fissure of Rolando.

The scalp having been marked according to this method, a horseshoe incision with the convexity pointing posteriorly was made; the flaps of integument and pericranium were raised and an inch trephine applied so that the center-pin was fixed on the line of what I had determined to be the course of the fissure of Rolando, and about half an inch inferiorly to the sagittal suture. The crown of the instrument was intended to embrace within its limits that portion of the skull immediately over the superior parts of the ascending frontal and ascending parietal convolutions. The button of bone was removed and the dura mater, arachnoid, and pia mater were found to be adherent to each other. While dissecting them apart a profuse hæmorrhage started from the anterior border of the wound which could not be arrested until half an inch more of the skull was removed with the rongeur. An artery was then tied and the hæmorrhage

* The Principal Fissures and Convolutions of the Cerebrum. *Lancet*, 1884.

immediately stopped. The surface of the brain was then cleansed of blood and the *débris* of bone, when it was found that a bluish membrane protruded, very much resembling in appearance the longitudinal sinus. Renewed examination showed that it could not be this vessel, and it was at once punctured with a sharp-pointed bistoury. Immediately a stream of serous fluid free from odor spurted out as if from a syringe to a distance of two or three feet, and continued to flow for about ten minutes with diminished force. The wound in the membranes was enlarged to the extent of half an inch and a probe was introduced; it could be passed downward and forward for about two inches without meeting with an obstruction. At this time the patient was in a state approaching collapse, and whisky was administered hypodermically. In a minute or so the pulse became better.

As the fluid still continued to flow from the opening in the skull and brain, I determined to introduce a drainage-tube. At once the fluid began to flow more freely. The tube was introduced along the line of the fissure of Rolando and passed in for three inches without meeting with obstruction. The button of bone was not replaced, but the wound was closed around the drainage-tube, which was left in place and through which fluid still continued to flow. Antiseptic dressings were applied and the patient put to bed. I may state that antiseptic measures were adopted throughout the whole course of the operation.

Soon after being put to bed the patient had a severe chill, which was stopped by putting bags of hot water to the body.

On emerging from the state of anæsthesia the patient was noisy and excited and complained of some pain in the head. A quarter of a grain of morphine was given hypodermically, and sleep ensued almost immediately; 9 P. M., patient still asleep, temperature 98·4°, pulse 120; profuse watery discharge from the drainage-tube, dressings being completely saturated; 12 P. M., patient still asleep; urine drawn off by catheter.

July 24th, 6 A. M.—Temperature 99·4°, pulse 164; milk and whisky administered; passed urine voluntarily; was quiet, talked rationally, although occasionally she made slight attempts to remove the dressings from her head; 8.45 A. M., temperature 99·8°, pulse 118. The dressings, being saturated with a watery discharge which still continued to flow, were removed and the brain cavity irrigated through the drainage-tube with a solution of corrosive sublimate (1 to 4,000). New dressings somewhat lighter in character were applied; one sixth of a grain of morphine administered hypodermically; 12 M., dressings changed, still saturated with the exudation from the drainage-tube; temperature 99°; 6 P. M., four grains of acetanilide to be repeated every four hours; 9.30 P. M., temperature 101°, pulse 132.

July 25th, 1.20 A. M.—Temperature 99·4°, pulse 120; 4.20 A. M., temperature 100·6°, pulse 130, vomited; 6.45 A. M., temperature 101·2°, pulse 142; digitalis normal liquor two minims, two ounces of whisky every two hours; 9 A. M., temperature 104°, pulse 150, body sponged with cold water, temperature falling almost immediately to 103°; 1.15 P. M., temperature 102·6°, pulse 144; the drainage-tube becoming closed, it was removed and a new one put in; one fourth of a grain of morphine administered hypodermically; 4 P. M., temperature 104°, pulse 156; patient quiet but easily aroused into activity, giving rational answers when spoken to; 5.45 P. M., temperature 102·8°, pulse 154; one eighth of a grain of morphine at 5 P. M.; acetanilide four grains, has been continued every four hours; 8 P. M., temperature 104·6°, pulse 160; 10 P. M., temperature 104·2°, pulse 150; 12 M., temperature 103°, pulse 140; one one-hundredth of a grain of digitaline hypodermically, to be repeated every two hours.

July 26th, 2 A. M.—Temperature 102·8°, pulse 156; 4 A. M., temperature 103°, pulse 156; one fourth of a grain of sulphate of morphine hypodermically; has been very restless all night; answers rationally when spoken to; asked to see her father and mother; 7.15 A. M., temperature 103·2°, pulse 156; 11 A. M., temperature 103·4°, pulse 156; one ounce of magnesia sulph.; bowels moved at 11 A. M. At 12 M., febricide pill given; 1 P. M., temperature 103·2°, pulse 156; 3 P. M., temperature 105·2°, pulse 156; ice kept to head; Dover's powder, six grains; 4.15 P. M., temperature 103·6°, pulse 168; 7 P. M., temperature 103·4°, pulse 154. Another febricide pill was given, and the body sponged with cold water; 8.15 P. M., temperature 101·4°, pulse 154; 11 P. M., temperature 102·8°, pulse 150; one sixth of a grain of sulphate of morphine at 12 P. M., hypodermically.

July 27th, 1 A. M.—Temperature 102°, pulse 138; 3 A. M., temperature 102·4°, pulse 150; 7 A. M., temperature 103°, pulse 156; rested very well during the night; 9 A. M., temperature 102·8°, pulse 154; 11 A. M., sponged with ice-water, the temperature falling almost immediately to 100·8°, but rising at 12.45 P. M. to 102·4°, pulse 154; 1 P. M., temperature 103°, pulse 158; 3 P. M., temperature 102·4°, pulse 148; has been in light stupor for the last twelve hours, from which she can be roused without much difficulty and answers rationally; 5 P. M., temperature 102·2°, pulse 144; 9.25 P. M., temperature 103°, pulse 146; very little discharge from the drainage-tube; probe passed entirely through it in order to ascertain whether it was open or not.

July 28th, 1.45 A. M.—Temperature 103·8°, pulse 156; 2.45 A. M., temperature 103·2°, pulse 154; 9 A. M., has been quiet all night, breathing regularly with but little acceleration; temperature 103·4°, pulse 160; 11.30 A. M., temperature 103·6°, pulse 168. From this time on the respirations became slower and irregular; the temperature remained at 104°, the pulse not falling below 160. Stimulants, which had been systematically administered, together with antifebrile remedies, such as acetanilide and febricide, no longer produced the slightest effect. It was evident she was sinking, and at times there was the Cheyne-Stokes respiration. Further medication was discontinued, as she was unable to swallow and was in a state of stupor. She remained in this condition through the afternoon of the 28th, and at 7 P. M. died, the sixth day after the operation.

The post-mortem examination was made on the following morning, the 29th, at 11 o'clock. The wound in the scalp had united by first intention, except at the point where the drainage-tube had been inserted. On removing the calvaria, adhesions were found to exist between the right frontal lobe and frontal bone, also thickening of the dura mater throughout the course of the longitudinal sinus extending for about an inch on each side. Nearly the whole of the right parietal lobe and upper and posterior part of the frontal lobe seemed to have disappeared, for the membranes were greatly collapsed. The operation appeared to have touched the superior apex of the depressed portion. There was slight congestion of the membranes of the left side, especially those covering the frontal lobe. The brain was removed and the membranes were opened; these were found thickened throughout their whole extent and were strongly adherent to the base of the skull and to each other, it being impossible to separate the dura mater from the membranes beneath. All these adhesions were evidently old. An incision was now made through the vertical axis of the membranes and a cyst was found coexistent with nearly the whole right parietal lobe, the convolutions of which portion had entirely disappeared. The ascending frontal convolution, except its inferior and horizontal portion, was also absent; otherwise the frontal lobe was in good condition. The anterior portion of the occipital lobe was also implicated, so that a portion of the middle and inferior convolutions had disappeared.

Inferiorly it was ascertained that the cyst involved likewise

the temporal lobe, and that the superior temporal convolution and about one half of the middle temporal convolution were absent.

Further examination showed that not a vestige of the island of Reil remained, that the anterior and external third of the caudate nucleus and a like portion of the lenticular nucleus of the corpus striatum were absent, and that the internal capsule was greatly atrophied. Continuing the dissection, it was discovered that the cyst was separated from the lateral ventricle anteriorly by a very thin lamina of cerebral tissue.

A second cyst of about the size of a large almond and involving the inferior temporal convolution was also found to exist. There were no cerebritis, no recent meningitis, and no

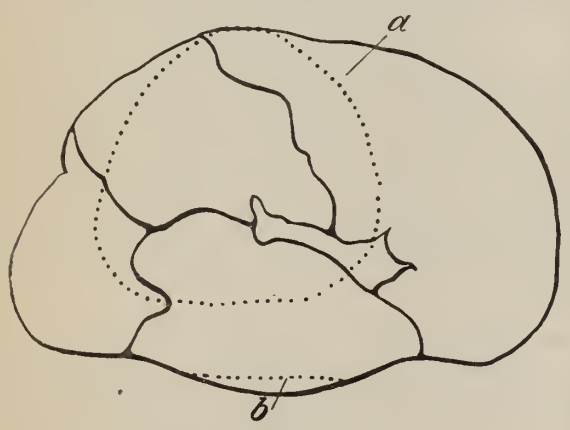

Fig. 3.

hæmorrhage. The extent of the lesion is seen in the woodcut (Fig. 3), where it is indicated by the dotted line *a*. The temporal cyst is shown in profile at *b*.

It is thus seen that the diagnosis was substantially correct, though the lesion was much more extensive than there was any reason to suspect. Probably the original disease was an extensive meningitis, the arachnoid being especially implicated in the regions where the cysts were discovered. It is certainly remarkable that life should persist for nearly nineteen years under such a condition of brain disease. The fact of the destruction of the island of Reil is interesting in connection with the circumstances that it was on the right side and that there had been little speech disturbance. In other respects it is seen that the case is strikingly corroborative of the doctrine of cerebral localization as laid down by Nothnagel, Ferrier, Exner, and others.

I should have mentioned that the contour of the right hemisphere indicated this half of the brain to be decidedly smaller than the corresponding left half.

In undertaking this operation I had no idea of limiting its extent by any other consideration than that of the requirements of the occasion. I was very confident that the morbid growth was not limited to the superior parts of the ascending frontal and ascending parietal convolutions, and I intended to remove, either by further trephining or by the rongeur, as much of the skull as might be requisite. The facts, however, that the growth was cystic and that the fluid was readily evacuated obviated the necessity of more extensive operative procedure.

In regard to the cause of death I have no very satisfactory explanation to offer. The patient had fully recovered from the shock of the operation, there was no recent inflammatory action anywhere in the brain or its membranes, and the wound was in a perfectly healthy condition, the scalp having united, as I have said, throughout nearly its whole extent. An examination of the lungs and kidneys was not permitted, but there is no reason for thinking that these organs were in a state of disease.

LOOK BEYOND THE NOSE.*

By SOLOMON SOLIS-COHEN, M. D.,
PHILADELPHIA.

The benefits of an enlightened and liberal specialism are so generally admitted that it is unnecessary to recount them. But while liberal and enlightened specialism has contributed and will continue to contribute in largest measure to the progress of medicine, there is a danger, a pressing and increasing danger, that narrow and unenlightened specialism will offer hindrance equally great.

There is a tendency, more especially upon the part of those who have had insufficient experience in general medicine—or perhaps not any—before undertaking exclusive practice, to magnify the importance of local lesions coincident with certain general disorders of the system, or with local disease in some other region. While this tendency is perhaps most strikingly manifested by some others, yet nowhere is it more pernicious than in the domain of rhinology. To discuss particulars rather than generalities, and selecting a single particular as type in order to save time —especially have malformations and enlargements of nasal tissues been advanced as the sole and efficient cause of persistent and distressing headaches.

That in some cases this is true the experience of competent observers places beyond question, but that it is true to anything like the extent one would infer from many contributions to the literature of the subject, my own experience at least leads me to doubt. In illustration of this fact I desire to report three cases, typical of many [illegible]

Case I.—Mrs. R., thirty-two years of age, consulted me in the hope of obtaining relief from a headache, which she said was dependent upon nasal trouble, and from which she had suffered more or less since she was twelve years of age, but more particularly during the last decade. She had been for something like two years—though latterly quite irregular in her visits—under the care of a specialist of ability, who had told her that her headache was due to trouble in the nasal cavities, although of what exact nature she had not been informed; and she had undergone several operations, two of them under ether. She did not know what had been done. During treatment antipyrine had been prescribed for temporary relief of paroxysms of headache.

Examination of the nose showed a badly deviated septum in contact with the middle turbinated body on the left side, a polyp attached to the middle turbinated body on the right side, with a general condition of chronic inflammation and thickening of the mucous membrane. The pharyngeal tissues were also thickened and inflamed. As a matter of course, the polyp was removed from the right nasal passage and the point of im-

* Read before the American Laryngological Association at its twelfth annual congress.

plantation cauterized. This, however, while it relieved some distress in breathing, had no effect on the headache, which was as persistent and as painful as ever. The nose was kept clean by an alkaline detergent wash, and as, notwithstanding the deviation of the septum, sufficient air was obtained for purposes of respiration, no further operative interference was undertaken, while the attempt was made to determine the course and cause of the headache independently of the nasal conditions. It was ascertained that there would be two or three days comparatively free from headache, and then for two or three days more a succession of paroxysms.

Studying these paroxysms, the fact was developed that they occurred principally in the afternoon—that is to say, while beginning in the morning, severity was not marked until about twelve o'clock, and the maximum of pain was reached at six o'clock in the evening, after which the pain gradually faded away. This suggested a possible malarial origin, and a history of attacks of intermittent fever, once previous to the first appearance of the headache and twice subsequently, was elicited. No enlargement of the spleen or liver was detected; heart and lungs were normal; nothing of pathological import was found in the urine. Unfortunately, the blood was not examined for plasmodia. The patient said she could not take quinine on account of the ringing in the ears soon produced; nevertheless, quinine hydrobromide was administered in doses of fifteen grains daily, divided into three portions, of which the first was taken upon getting up in the morning, about seven o'clock, the next at ten, and the next at twelve. In addition, five grains of salicin with two of ergotin were taken at 6 P. M. and again at bedtime. The first day there was a slight headache about four o'clock in the afternoon which lasted but a short time. The same thing occurred the following day, and the daily dose of the quinine salt was increased to twenty grains. Since that there has been increasing freedom and finally no return of headache for a period of more than a month. Medication has been modified accordingly. The patient states that in twenty years she had not previously been free from headache for a week. This is an exaggeration I believe, but it may be accepted as a fact that, at least, she is very much better now than at any time during that period, and that the improvement is due to constitutional and not to local treatment.

The nasal septum remains deviated and in contact with the middle turbinated body.

Case II.—Mr. Y., aged twenty-one, has a deviated and thickened septum in contact with the middle turbinated bodies on both sides, a posterior enlargement of the lower turbinated body of the right side, and also engorgement of the erectile tissue upon each side of the bony septum posteriorly. He has no reflex troubles of any kind, and says he does not know what headache means.

Case III.—Miss X., aged twenty-seven, has had excruciating headaches and occasional periods of insomnia for years, and has been under the treatment of a number of practitioners specialists in various lines.

The first physician whom she consulted—a woman—attributed her troubles to the uterus, and she was for three months an inmate of a sanitarium, undergoing special treatment. Her next adviser scouted the uterine theory and found a sufficient cause for her distress in refractive errors of the eyes, which he corrected. The third believed it to be entirely nervous, curable by electricity, which he applies indeed to the treatment of all diseases, and she says that he benefited her more than either of the others. The fourth, fifth, and sixth were homœopathists, the seventh a gynæcologist, and I had the honor of being the eighth. At this time the patient was under the idea that the nose was the *fons et origo mali.*

I found deviation of the septum, thickening of the nasal mucous membrane, and engorgement of the glandular tissues of the vault of the pharynx. In order to determine whether the nose was really the source of this patient's long-continued distress, I treated it, and succeeded in relieving what slight nasal symptoms existed and in so far rectifying the deviation of the septum as to obviate any contact of tissues; but neither the headache nor the insomnia was benefited in the slightest degree. The patient was hysterical, there could be no question of that; but careful inquiry into her general health showed a condition of feeble digestion and atony of the intestine associated with gastro-intestinal catarrh and a consequent lithæmia. Treatment was directed to this condition, with improvement, but not absolute cure. Becoming dissatisfied with her slow progress, the patient consulted a ninth adviser—a second oculist, who, I know, had never practiced medicine. He found that the previous correction had been all wrong, and consequently had aggravated instead of relieving her headaches and general nervous mal-condition, while his correction was bound at once to restore her to robust health and freedom from pain. That it did not do so is evidenced by her return to me some two months later, when the constitutional treatment was resumed. The patient was not well, but very much improved when I last saw her, and I have no doubt that proper regulation of diet and of daily life carried out faithfully would eventually relieve whatever actual physical pain is present.

These cases are cited simply as instances of what must be common in the practice of every physician who is competent to examine the nose, but also mindful of the facts not only that there are other organs in the human body, but that there is, too, such an entity as a whole organism, not to be looked upon merely as a thing of shreds and patches.

There are conditions of headache and other nervous disturbances, including asthma, dependent doubtless upon nasal lesions; but men, at least those who, like myself, are in active general practice, meet with a far greater number of cases of these conditions in which there is no nasal abnormity, or in which nasal abnormities are not causative but merely coincident. Furthermore, every fellow of this association must have seen quite a large number of cases—a large majority indeed—of nasal lesions in which none of these nervous phenomena were manifested, as well as many cases in which nasal symptoms themselves were dependent upon systemic causes. The conclusion draws itself; there is no need for elaboration. It is simply this: Let us examine the nose as well as the other organs of our patients, either as a matter of routine or when special indications present; let us treat *secundum artem* whatever nasal condition demands treatment; but let us not forget also to look beyond the nose.

A CASE OF MYXOMA OF THE NASO-PHARYNX IN A CHILD SIX YEARS OLD.*

By ALEXANDER W. MacCOY, M. D.,
PHILADELPHIA.

The recital of the history of the following case of myxomatous tumor of the naso-pharynx is given because of

* Read before the American Laryngological Association at its twelfth annual congress.

the rarity of such growths in this region, and also because the extreme youth of the subject adds even more to the rarity. My fellow-members have probably had similar cases in *their* experience, but I am not aware that many such pathological conditions have been put on record by them.

In a rather extended experience in private and hospital practice, this is the first case of the kind which I have seen in so young a child. The occurrence of myxomatous tumors in the *nasal* passages of children is rare, even making due allowance not only for the cases already reported, but also for those not in print, of which we have verbal knowledge. In my own experience I can recall but one case of nasal polypus in a child, and this occurred in an infant under one year of age.

It was seen in the right nostril upon anterior inspection, blocking the respiratory tract, and was removed by the Jarvis snare. This case came under observation in 1883, and during the seven years which have elapsed since I have not seen a similar case. While we seldom see myxomatous development in the nasal chambers of children, the dictum enunciated by Lennox Browne that "polypi may occur at any age" is undoubtedly true. This statement of Browne's should, however, be qualified by acceptance of the doctrine that all myxomatous degeneration or development is dependent upon a prior inflammation in the regions where it occurs; and that the inflammation must have been of some duration. The rarity of these myxomatous developments in childhood can be explained by the fact that there are few children who have had chronic colds of sufficient duration to develop the pathological changes necessary for the growth of polypi. This is not only dependent upon the fewness of years, but also upon the ability of youth to resist true hypertrophic changes. What has been said in explanation of the rarity of myxomatous changes in childhood in the *nasal* chambers applies with even more force to similar changes in the *naso-pharyngeal* region. Myxomatous development in the naso-pharynx is still more rarely noticed in children—if we accept the consensus of opinion as expressed in literature.

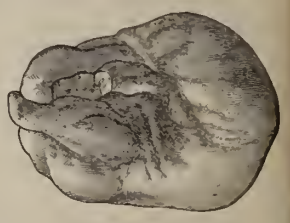
The following case came under my notice in February, 1890. The subject of this history was a patient of Dr. Kennedy, of Clifton Heights, who kindly asked me to examine the case with him.

Dr. Kennedy had already clearly made out the tumor, and came for an opinion as to its nature, and also as to measures for its removal. The notes of this case up to the date of removal have been kindly furnished to me by Dr. Kennedy, and are as follows:

Annie L., aged six years, had always enjoyed good health until September, 1888, at which time she contracted a heavy cold by the practice of wetting her hair. This acute coryza developed into a chronic rhinitis. Complete occlusion of the nostrils did not take place until March, 1889, from which time she has not been able to breathe through the nostrils. Through June and July, 1889, she became greatly emaciated; her mouth was kept wide open. There was rapid respiration and loss of appetite. The physician and family were fearful that she would die. She quickly responded to proper remedies and regained her general health. An examination revealed complete occlusion of both nostrils. From the nostrils poured a muco-purulent discharge which filled the nasal chambers. Mouth-breathing was absolutely necessary for respiration. The voice was flat and thick. The expression of the face was quite similar to that seen in cases of hypertrophy of the pharyngeal tonsil.

Examination by the rhinoscopic mirror revealed a large, pale-pinkish mass completely filling up the naso-pharyngeal region. The growth did not show below the soft palate, but could readily be seen upon elevating the palate. There was considerable discharge from the naso-pharyngeal space; not much redness of the fauces, and only a moderate bulging of the soft palate. Examination with the finger showed a large, elastic tumor; the finger could, with some difficulty, be made to pass around the growth. It was only slightly movable and appeared to be firmer than a myxomatous tumor, but not so dense as a fibroid. An attachment (of about half an inch in diameter) was clearly made out, springing from the free surface of the vomer and confined to the lower part of it.

On February 28, 1890, the tumor was quickly and successfully removed (after the application of cocaine and etherization) by the galvano-cautery snare. The long loop of wire was passed through the nostril and gradually insinuated along the upper surface of the soft palate until it could be felt by the finger in the naso-pharynx, when it was widened and carried back to the posterior wall of the pharynx and pushed up by the finger until it could go no farther; the loop was then reeled in, the finger acting as a guide to the base of the growth. After the wire had been firmly tightened, the current was turned on and the pedicle cut through. The tumor failed to "materialize" in the fauces, and the finger had to be inserted into the naso-pharyngeal space and hooked around it, when the tumor fell out of the open mouth upon the floor. There was but a trifling hæmorrhage. Afterward the child had no reaction, and at once the functions of the nasal chambers were completely restored. Since the date of removal the child has enjoyed perfect health. There has been no recurrence.



The tumor (which I offer for your inspection) weighed six drachms and was pyriform in shape. The report of the microscopic examination is as follows:

"Dear Dr. MacCoy: Dr. Packard has made sections of the tumor which you removed from the posterior nares of a child. Its pedicle is composed of loose-meshed fibrous tissue, while the body of the growth from without inward is made up of an envelope of epithelium, a layer of soft fibrous tissue interspersed with elastic tissue, and a center composed of myxomatous tissue through which are scattered numerous round lymphoid cells. The tumor bears the general characteristics of a submucous myxoma. Yours truly, G. W. Schweinitz."

I have also had prepared a micro-photograph of the sections.

A CASE OF FIBROSARCOMA OF THE RIGHT NASAL FOSSA, WITH UNUSUAL CLINICAL HISTORY.*

By CHARLES H. KNIGHT, M.D.

The following report is robbed of much of its value by the absence of post-mortem observations, yet the occurrence of several remarkable phenomena as the case progressed

* Read before the American Laryngological Association at its twelfth annual congress.

seem to make it worthy of more complete record. The specimen herewith exhibited occupied the naso-pharynx, but is no doubt a portion only of a neoplasm which had its origin within the nasal cavity. The patient came to the Throat Department of the Manhattan Eye and Ear Hospital in September, 1886, giving the following history:

P. D., aged forty-two, baker, married. Family history good. Patient has had no illness since childhood. About twelve years ago he received a violent blow on the bridge of the nose. The precise extent of the injury sustained is not known. For the last two years he has had more or less nasal obstruction and catarrhal discharge. The sense of smell has become impaired, and he has been annoyed by frequent sneezing and pretty constant frontal headache. His friends have noticed a marked change in his disposition. He has become irritable, surly, indisposed to work, and, contrary to his previous habit, has often taken liquor to excess. He has had no hæmorrhages until two months ago, when he expelled from the right anterior naris masses of bloody tissue, and at about the same time hawked out from the posterior nares a fleshy mass as large as a robin's egg. Two weeks ago the right eye became almost closed from an œdematous swelling of the lids, and there was considerable swelling and sensitiveness in the right infra-orbital region.

On examination, the right naris was found completely occluded by a soft, vascular, and very sensitive mass, somewhat resembling an old myxoma. It extended quite to the margin of the nostril, and with a rhinoscopic mirror a growth as large as a hickory-nut could be seen projecting into the naso-pharynx. No glandular enlargements could be discovered and there was no cachexia. An attempt to surround the growth with a loop of wire caused profuse hæmorrhage and extreme pain, upon which cocaine had no effect. A large piece was finally removed from the anterior portion of the tumor by means of a cold wire snare. The growth reproduced itself with astonishing rapidity, and when examined three days later it had almost regained its original dimensions. Under the microscope the appearances characteristic of fibrosarcoma were seen.

The patient then went to the New York Hospital, where Dr. Weir performed Chassaignac's operation (November 15th). An incision was made across the nose at the level of the eyes downward and along the right labio-nasal junction to the left ala. The nasal bones were sawed through and the nose tilted to the left so as to expose the tumor. A quantity of soft growth was removed by means of the curette and the wire loop, when it was found that the neoplasm invaded the ethmoidal and sphenoidal cells, and that it could not safely be further followed. The cavity was packed with iodoform gauze after closing the external wound with sutures. The patient made a good recovery from the operation.*

Six weeks afterward (December 27th) he reappeared at the Manhattan Eye and Ear Hospital with his nostril blocked by a recurrence of the neoplasm, and complaining of amblyopia and impaired vision in his right eye. There was marked divergent strabismus. In the course of a week (January 11th) the sight in that eye was completely lost. He could not distinguish light from darkness. At this time an ophthalmoscopic examination by Dr. Roosa, Dr. Emerson, and others showed no change in the fundus. A week later (January 18th) the left eye began to lose its power. Still the ophthalmoscope discovered nothing abnormal. The process went on until in two weeks (February 1st) he became totally blind. There was no impairment of hearing and no muscular paralysis. The tumor then projected from the anterior naris, and the line of Weir's incision was breaking down. It filled the naso-pharynx to such an extent as to interfere seriously with speech and deglutition. Several attacks of wild delirium had occurred in which the patient had attempted to jump from the window. No rise of temperature was noted. Two weeks later (February 14th) the right eye and side of the face had disappeared beneath a fungoid mass of friable, vascular tissue, from which there was constant oozing of bloody serum. The fœtor was almost intolerable. The tumor had extended backward, so that speech was unintelligible and dysphagia was extreme. But little nourishment could be taken, and the patient had become much emaciated. He had various mental hallucinations and was at times violent. Most of the time he was in a condition of stupor.

Just a week from the time of the last visit (February 21st), about three months from the date of the operation and less than five months after he first came under observation, I received an urgent summons, as the patient was said to be bleeding to death. On reaching him, I found a most ghastly spectacle. It seems that during an attack of delirium a short time before he had torn off a portion of the tumor from his face, and had also passed his fingers into his mouth and dragged out an irregular mass, which was probably that part of the tumor filling the naso-pharynx. The rush of blood was so profuse as almost to suffocate him, and in a few moments he was thought to be dead. On my arrival, the bleeding had ceased, but the patient and the bed on which he lay were covered with blood. His breathing was rapid and shallow, his pulse was hardly perceptible, and he was in a comatose condition, from which he could not be roused. Death occurred in about five hours. An autopsy was not permitted.

It would have been interesting to determine, if possible, the origin and distribution of this neoplasm. The early period at which indications of invasion of the cranial cavity appeared would suggest that the growth probably began in the sphenoidal or ethmoidal cells, thence extending both upward and downward. Such being the case, no operative interference could have been very promising, yet resection of the jaw would have given better access to the region affected, and might have permitted a more radical removal of the growth. On this point Weir thus expresses himself: "Irrespective of the cerebral extension, it would have been better in this case to do the usual partial resection of the jaw, according to Maisonneuve's suggestion, as this would not only have allowed a more thorough extirpation of the growth, but would have enabled one to detect and to treat early any recurrence."

In the words of Butlin, as found in his work on *The Operative Surgery of Malignant Disease*, "it is almost always necessary to remove at the same time some of the surrounding tissues—in some instances a very wide area—in order to prevent a local recurrence of the disease." In cases of this class it is often difficult to determine beforehand the exact origin and situation of the neoplasm. Hence it is doubly important, if any operation be undertaken, to select one which will give us the most ample opportunity for thorough inspection of the region. Partial and palliative operations should be discouraged, except in so far as they may be demanded for the removal of obstruction to swallowing or breathing, or for the arrest of hæmorrhage.

It is doubtless true that malignant tumors of the naso-pharynx and those of the nasal fossæ do not belong in pre

* *N. Y. Med. Jour.*, March 12, 1889; also Case XXXV in Bosworth on *Diseases of the Nose and Throat*, p. 444.

cisely the same category; the former, being more accessible, may therefore be more completely engaged in the loop of an écraseur, or may come within the scope of less formidable procedures, such as electrolysis. But a large proportion of these cases come to us when the limitations of the neoplasm can no longer be clearly defined. We can not with certainty determine its attachments. The principle suggested by Butlin seems to apply as strongly to malignant disease here as elsewhere. If extirpation be attempted, we must be sure that *more* than the diseased tissue is included, in order to insure a successful result. We hear of many instances in which an operation was begun and soon abandoned because the growth was found to have passed the line of safety. Recent literature gives us contradictory opinions as to the best method of attacking cases of this kind. At the close of the report of a case of naso-pharyngeal carcinoma in the *New York Medical Journal* for March 8, 1890, Dr. Sidney Allan Fox recommends "thorough removal, from time to time, of the growth with the post-nasal cutting forceps and wire snare." He maintains that in this way the removal may be radical (?), and, under cocaine, almost devoid of pain. He objects to the various capital operations, on the ground that they are dangerous and cause more or less mutilation.

On the other hand, in a memoir on The Diagnosis and Treatment of Malignant Tumors of the Nasal Fossæ, in the *Annales des mal. du larynx*, etc., March, 1890, and translated in the May number of the *Journal of Laryngology and Rhinology*, Dr. A. F. Plicque takes a very decided stand as to the use of forceps for ablation and the wire snare. In speaking of pedunculated malignant tumors, he says that they should never be removed in this manner, but always by an external incision. The latter opinion would seem to commend itself to our judgment. Many cases are on record in which the surgeon has endeavored to satisfy himself with milder measures and has finally been compelled to resort to the more radical method. Meanwhile valuable time has been lost, and the patient may be in poor condition to withstand the shock of the major operation. Moreover, the growth has been extending, thus diminishing the probability of thorough extirpation, and increasing that of local recurrence and generalization.

The conclusion seems, therefore, to be forced upon us that when we have determined to attempt the removal of a malignant tumor of the nose or naso-pharynx, *the extent or implantation of which is in doubt*, we should approach it by an external incision, removing enough of the bony structures to permit us to trace the neoplasm to its origin.

In connection with the case which has been reported, another question of interest presents itself. Did the traumatism received ten years before the beginning of symptoms bear a causative relation to subsequent developments? We are familiar with the influence of prolonged irritation in the ætiology of certain forms of malignant disease, as epithelioma of the lip and chimney-sweep's cancer, and it is the general custom to search for a history of injury in cases of carcinoma. Watson, in his work on *Diseases of the Nose*, page 282, says that recurring nasal fibromata show a tendency to assume a sarcomatous type, and Bosworth (*Diseases of the Nose and Throat*, page 445) reports a case in which sarcoma developed after "polypi had been operated on rather harshly by means of forceps."

A similar case has been reported by Heymann.* A patient who had several times been operated on for nasal polyp finally appeared with a large intranasal tumor, which, on extirpation, proved to be a melanotic sarcoma, at many points undergoing carcinomatous degeneration. Cases of spontaneous transformation are rare. The observations of Michel, Hopman, and Schaeffer lack certain essentials. The only authentic case on record seems to be one reported by Bayer,† which was verified by microscopical examination and proved to be a villiform carcinoma implanted upon a simple mucous polyp. In looking over the forty-one cases collected by Bosworth, we find no light thrown upon this question. Yet it is one which from a medico-legal standpoint might be of some importance. For example, in my own case the patient himself and his friends were convinced that his nasal trouble was the direct consequence of a blow, and it was seriously proposed to have his assailant arrested. There is, however, a marked disproportion between the number of cases of malignant disease of the nasal fossæ and of injury to the nose. Hundreds of cases of nasal myxomata, requiring many operations and involving no small degree of traumatism, come yearly to our clinics, yet not more than a dozen cases can be found in which malignant degeneration of a benign growth can be suspected. It would seem, therefore, that we can not justly attribute to traumatism a causative agency; to repeat an opinion elsewhere expressed—it alone is not capable of creating malignancy.

A CASE OF RABIES FROM THE BITE OF A SKUNK.

By N. S. JARVIS, M. D.,
FIRST LIEUTENANT AND ASSISTANT SURGEON, U. S. ARMY,
FORT VERDE, ARIZONA.

(*Published by authority of the Surgeon-General.*)

The following case will go further to encourage the tradition that the bite of the skunk is productive of rabies. Whether the term "rabies mephitica," applied by Janeway (*Med. Record*, March, 1875), is scientifically correct or not I can not say, but I am compelled to admit, from my observation of this case, that one would naturally adopt the term "rabies" were he familiar with the clinical phenomena of that terrible malady.

On the 10th of May, 1890, Dr. William Stephenson, at that time post surgeon at Fort Verde, was called upon to attend Charles Morris, a settler living in the vicinity of the post, who stated that the night previous he had been bitten on the nose by a skunk while asleep on the ground some miles down the valley. The wound was located at the junction of the osseous and cartilaginous portions of the nose, and the impressions of the animal's sharp teeth were distinct.

Dr. Stephenson, I am told, carefully washed the wound and injected into the tissues a saturated solution of potassium permanganate. On the morning of June 16th I was asked to visit

* *Rev. mens. de laryngologie*, etc., No. 1, 1888, p. 24.

† *Rev. mens. de laryngologie*, etc., January, 1887, p. 17.

Mr. Morris, who had come from his ranch to the post trader's store and awaited my arrival there. I called at 9 A. M. and found the patient impatiently walking the floor and apparently in great alarm; he had been seized with peculiar tingling pains originating from the wound the day before, and had slept none during the entire night. The wound had healed entirely some time since, leaving a bluish-colored cicatrix. The peculiar sensations complained of starting from this scar he described as shooting over the entire scalp. He also stated that he could barely "catch his breath," and experienced a sense of weight in the epigastric region, with difficulty of swallowing.

Morris was a robust man, forty-nine years of age, had always been healthy, but had, I understand, been considerable of a drinker for some years. Nearly every family in these frontier settlements is supplied with what they term a "doctor book," such as Gunn's *Family Medicine*, Foote's *Household Medicine*, etc. Thinking that Morris had been reading about the symptoms of hydrophobia and was suffering from the effects of his imagination, I tried to divert his mind by assuring him of the absurdity of the idea, and, to further quiet him, administered potassium bromide every hour.

At 1.30 P. M. I called, and the patient stated that the tingling sensations were not so frequent, but the abdominal pain and gasping were still prominent. He was unable to swallow water except in very small quantities. His pulse was slow and full, the skin clammy and covered with perspiration. Irritation of the wonnd on the nose immediately produced irregular convulsive movements of the whole frame. The abdominal pain seemed to be produced by spasmodic contractions of the diaphragm; the breathing was short and jerky.

At this time I administered a hypodermic injection of eight minims of Magendie's solution, and was surprised to see the entire absence of its usual soothing effect. I directed that the patient be kept in a darkened room and as quiet as possible. At 8.30 P. M. I found no abatement in the symptoms; the apparent attempts to vomit some irritating substance were frequent and weakening. He was utterly unable to swallow liquid or solid food, yet complained of extreme thirst and hunger. I then administered half a grain of sulphate of morphine and one sixtieth of a grain of sulphate of atropine by hypodermic injection. The patient rested quietly for about two hours, but on awakening at the expiration of that time the symptoms returned in all their intensity. He would frequently jump suddenly from the bed and rush toward the door as if to inhale fresh air. The occurrence of the shooting pain would elicit a shudder from his entire frame as if he were suddenly subjected to a chill. I again administered an injection of morphine and atropine, and, leaving some to be given during the night should his paroxysms continue, left the patient at 10.30 P. M., returning early the next morning (June 17th). I now became thoroughly alarmed at the man's condition. Attempts to swallow were futile; the liquid, regurgitating into the nostrils and entering the larynx, aggravated the attacks of dyspnœa. Saliva flowed from the mouth and gathered in foamy masses on the mustache and on the cheeks. The pulse was still slow, but was not so full and strong as on the previous day. The spasmodic contractions of the diaphragm were frequent and painful and the patient was uncontrollable in his restlessness.

I then attempted to relieve the symptoms by inhalations of amyl nitrite, twenty-five minims being placed on a soft rag and applied to the nostrils. Although sufficient was used to affect all in the vicinity of the patient, the effect upon him was practically *nil*. Chloroform was administered with no effect except to alarmingly weaken him. Beef extract and brandy were administered by rectal injection and were well retained. The patient passed his urine several times during the previous day and on this morning, but had no evacuation from the bowels. Morphine sulphate and atropine were then administered in quantities sufficient to narcotize a healthy man, but with little or no result. The patient's struggles for breath and attempts to vomit were extremely pitiful; he assumed every position, at times walking on all fours, groveling on the floor and rushing from one part of the building to another. At the same time the abdominal contractions and gasping attempts to fill his lungs produced a sound similar to the croupy cry of a child. It occurred to me that this was the so-called "bark" of a hydrophobic victim, which the newpaper descriptions usually contain. In order to restrain the patient, I was compelled to handcuff him and tie his shoulders and feet by stout rope to the cot on which he was lying. In fact, he requested it himself, possibly fearing lest he should do some injury to those around him. At about 1 P. M. he expelled a large quantity of blood from his throat, some of which entered his trachea and produced the most painful struggles. The slightest touch or motion would give rise to the peculiar shuddering movements of the body. From this time on the pulse began to fail, and the poor wretch expired suddenly at 5.30 P. M., evidently by sudden paralysis of the muscles of respiration. An autopsy was not obtainable. Except toward the last two hours, his intellect was clear.

I leave it to those who have witnessed cases of hydrophobia to say whether one would be justified in applying that term in this instance; I had never observed a case before, and my knowledge of the agonizing malady is based upon a perusal of the literature of the subject. The fact that two men in this vicinity have died with similar symptoms after the bite of a skunk within the last ten years would certainly justify me in believing that the bite of this animal is at times poisonous, if not productive of rabies. The skunk escaped after inflicting the wound in this case.

I notice that Dr. Sears, at the recent convention of the American Medical Association, stated that the bite of the polecat frequently produced rabies (*Med. Record*, June 7, 1890, p. 664). See also article by Acting Assistant Surgeon J. A. Wolf, *American Journal of the Medical Sciences*, October, 1875.

SUPPLEMENTAL REPORT ON CARTILAGINOUS TUMORS OF THE LARYNX AND WARTY GROWTHS IN THE NOSE.*

By E. FLETCHER INGALS, A. M., M. D.,
CHICAGO.

At the meeting of the American Laryngological Association, held in Washington, September, 1888, I reported the case of a young man suffering from a cartilaginous tumor, just beneath the vocal cords, which grew from the lower portion of the thyreoid cartilage. This growth I had been treating by the local application of chromic acid in full strength.

At the time the growth seemed to have been practically cured, but the following month the patient again consulted me, when I found a slight thickening of the right half of the base of the tumor. I again cauterized the growth with chromic acid, and subsequently, on one or two occasions,

* Read before the American Laryngological Association at its twelfth annual congress.

similar applications were made, with the effect of completely destroying it. During the past year there has been no recurrence, and now the patient may fairly be pronounced cured. In this case the growth measured originally one centimetre in diameter by seven centimetres in thickness. Internal remedies and local applications of various kinds had done no good, and finally there seemed no way of removing it, excepting by laryngotomy, until I tried the plan of gradual destruction by chromic acid. Altogether twelve or thirteen applications of the acid were made, a mass of the fused acid about as large as a millet seed being used each time. Owing to the patient's business, intervals of from three weeks to several months intervened between the various cauterizations. At present the parts appear normal; even the mucous membrane shows no cicatrix, and the thickening has entirely disappeared. The acid seems to have caused absorption rather than destruction. Intense congestion followed each cauterization, but I never observed ulceration of the parts after the applications. However, I seldom saw the patient for several weeks after cauterization. From the final result in this case I can strongly urge a faithful and long-continued trial of this method of treatment in laryngeal growths which can not be thoroughly eradicated by forceps.

At the last meeting of this association I reported a case of warty growths in the nose which I had cauterized from time to time with chromic acid, nitric acid, nitrate of silver, or the galvano-cautery. I had hopes of curing the case by these agents, but the warts continued to return. For about two months after my report was written I either applied chromic acid or used the galvano-cautery about once a week for the destruction of all warty growths that appeared. On the 7th of August, 1889, I applied to the growth the tincture of thuja occidentalis and gave to the patient the same preparation, which he was directed to apply twice daily with a pledget of cotton, which was to remain for twenty minutes. At the same time he was told to take internally teaspoonful doses of the remedy three times each day. He made the local applications faithfully and for a few days took the medicine internally with considerable regularity, but afterward he limited the treatment to local applications. During the next ten weeks I saw the patient eight or ten times and made six or eight applications of chromic acid to small warts as they appeared. At the end of this time I find it noted in the record that there was no appearance of warty growths. The patient still used the thuja occidentalis locally, though not with great regularity. Subsequently the mucous membrane of that side had a tendency to become dry, for which it was treated from time to time with various remedies. About a month after the final disappearance of the warts the patient was given a spray of two grains of carbolic acid and two grains of camphor to the ounce of liquid albolene, which he used for a short time. It is now seven months since the last of the warty growths were destroyed and none have returned. What the influence of the thuja occidentalis has been upon this case it is impossible to say; but, from its time-honored reputation for curing warty growths and from the fact that previous remedies had failed, I think it fair to give it a portion of the credit, though doubtless the occasional use of chromic acid had something to do with the result; however, during the treatment it was very apparent that the growths did not reappear as quickly, and that they enlarged much more slowly after the thuja occidentalis had been in use a short time.

UNILATERAL PARALYSIS OF THE LATERAL CRICO-ARYTÆNOID MUSCLE.

(LATERAL ADDUCTOR OF THE VOCAL CORD.)

*PECULIAR CASES.**

By E. FLETCHER INGALS, A. M., M. D.,
CHICAGO.

Although bilateral paralysis of the adductors of the vocal cords is a common affection, unilateral paralysis is not often met with excepting as the result of compression or injury of the recurrent nerve, as, for example, in aneurysms of the aorta or malignant disease of the œsophagus. The affection is, however, met with in rare instances of lead and arsenical poisoning, and it is sometimes observed as the result of exposure to cold. It is sometimes attributed to rheumatism or phthisis, and is occasionally seen as the result of accident or surgical wounds. When accompanied by paralysis of the same side of the tongue or palate it is of centric origin. Two cases which I wish to report, although following shortly after surgical operations in the mouth and naso-pharynx, appear to be of hysterical character, though one would seem to prove that an injury to the terminal extremities of one branch of the eighth pair may, through reflex influences, produce paralysis of distant muscles supplied by an entirely different branch of the same nerve, and the other would appear to indicate that, in the same way, paralysis may be produced in one of the distant muscles supplied by the pneumogastric branch of the eighth pair, while the injury causing it occurred to the terminal loops of one of the branches of the fifth pair.

In these cases the usual dysphonia was present and the sounds produced by coughing or sneezing were more or less altered. In neither were there evidences of hysteria or symptoms indicating constitutional disease. There was neither swelling nor congestion of the larynx in either case, and in neither was there any evidence of injury to the recurrent nerve. The first patient recovered after a few weeks of, mainly, constitutional treatment; the second had been treated by another physician for over two months before coming to me, and has now been under my care for about four weeks without perceptible improvement.

Case I.—Miss M. P., aged twenty-two, school-teacher. This patient told me that two weeks previously she had some teeth extracted, which caused her to faint, and that twenty-four hours later the voice was suddenly lost so that she could only speak in a whisper, but her voice had considerably improved. When she consulted me she spoke in a coarse whisper and complained of slight pain at times in the left shoulder and back and of some difficulty in swallowing, which had been present since the voice was first lost. Otherwise she was in perfect

* Read before the American Laryngological Association at its twelfth annual congress.

health; the appetite was good and digestion normal. I found the voice of about one half its normal intensity. There was no difficulty in respiration and no cough except when attempting to swallow fluids. She was despondent for fear of being unable to return to her work, but there were no evidences of hysteria. There was evident paresis of the depressors of the epiglottis, as indicated by her difficulty in swallowing, though the condition was not discernible upon laryngoscopic examination.

Examination of the vocal cords showed absence of either congestion or swelling. On phonation, the left cord passed about three millimetres beyond the median line, but the right one remained motionless at the side of the larynx. At her first visit I applied a simple stimulating spray to the larynx and ordered pills containing iron and quinine with one twentieth of a grain of strychnine in each. At her second visit the same local application was made and the strychnine continued, though the other remedies were changed. A week later there had been no material improvement. The faradaic current was then applied to the cord itself by means of a double electrode. The internal remedies were continued. A few days later the faradaic current was again employed and the dose of strychnine was increased to one sixteenth of a grain. Four days later the same treatment was repeated. At her next visit (twenty days after she had first consulted me) it was noted that, although the right cord itself was motionless, the tissues covering the right arytænoid cartilage moved considerably on phonation. Three days later there had been slight, if any, improvement. The faradaic current was then discontinued, but the strychnine was increased to one twelfth of a grain three times daily. From this time on I made no local applications. About a week later, as the patient wished to return to her home in the country, I increased the dose of strychnine to one tenth of a grain and gave her in addition a grain and a half of quinine, a grain of the valerianate of zinc, and one fortieth of a grain of nitrate of sanguinarine three times a day. She was allowed also to apply the faradaic current over the larynx as suited her inclination. I heard nothing more from the patient for five weeks. During that time she had continued the treatment, and she then reported herself completely cured. There was no subsequent return of the dysphonia. Some months later I saw the patient and found that the paralysis had entirely disappeared.

Case II.—Miss L. B., aged nineteen. This patient came to me in the latter part of March on account of difficulty in speaking, which not only interfered with her ordinary voice but prevented singing. She stated that for a year and a half she had been troubled with catarrh, and that recently she had been under the treatment of another physician for this affection. He had found enlargement of Luschka's tonsil, which he had removed at two different operations. The first operation gave her much pain, but at the second operation cocaine was used more freely and there had been little or no suffering. Upon the day following the second operation she had been comfortable and had used her voice more than usual, but on arising the next morning—that is, two days after the operation—she found herself unable to speak louder than a whisper. This occurred eight weeks before the time she first consulted me. In the mean time her voice had gradually improved until at the time I saw her she could speak aloud in a husky tone, but she was unable to sing. During these two months she had been under the treatment of her physician, and had received several applications of the faradaic current. Her general health was excellent and she had no cough or dyspnœa.

I found the nares and naso-pharynx essentially normal, but there was some inflammation of the Eustachian tubes. Upon examination of the larynx, I found the right vocal cord completely abducted and immovable upon attempted phonation. There was no congestion or swelling of the parts. I applied the static current and recommended the internal use of strychnine, but she did not place herself under my care until nearly two weeks later. Upon her return, I applied to the Eustachian tubes and middle ear an oily solution of carbolic acid, gr. ij, and menthol, gr. v, in liquid alboline, ℥ j. This was introduced through the naso-pharynx by means of my ordinary atomizer, with a long bent tip, the nostril being held while the spray was being thrown in. I applied to the larynx a slightly stimulating spray, mainly for its psychical effects, and used the static current externally over the larynx. Thereafter she took sulphate of strychnine in gradually increasing doses until she experienced a peculiar nervousness about twenty minutes after taking the medicine. This did not occur until the dose had reached one tenth of a grain three times daily. It was found that half this dose could be taken six times daily without inconvenience, therefore this method was adopted. The case is still under treatment. On phonation, the supra-arytænoid cartilages of the right side move a little, but the vocal cord remains motionless and the left cord nearly meets its fellow far to the right of the median line. The question has arisen in my mind whether this paralysis could have preceded her attack of aphonia, but everything in the history of the case seems to prove that it did not, and the most critical examination fails to detect any other than a hysterical origin, either centric or along the course of the pneumogastric or recurrent laryngeal nerve.

This patient was completely cured in four weeks after the foregoing was written, and there has been no recurrence.

STUDIES IN THERAPEUTICS.
THE PHARMACOLOGY OF ERGOT.

By JOHN AULDE, M. D.,
PHILADELPHIA.

The dangers from the use of ergot are not so great as one would suppose from a study of the effects upon the system. Large doses, short of poisoning, if continued for a sufficient time, will cause paralysis, and anæsthesia with coldness of the surface, these phenomena being due to a lack of blood-supply to the affected tissues, as will appear further on in this discussion. When given in sufficient quantity, ergot produces all the symptoms of an irritant poison, such as nausea, colic, giddiness, dilatation of the pupil, with dimness of vision and stupor, often accompanied by diarrhœa and vomiting. Poisoning is referred to as ergotism, and epidemics have occurred at different times in countries where rye-bread forms a food-staple, but the system appears to be very tolerant of large doses given for medicinal purposes. Ergotism presents two varieties of symptoms; they may be simply gangrenous or in the nature of nervous manifestations—such as formication, paralysis of sensation in the extremities, sclerosis of the postero-lateral columns, and possibly epileptiform seizures. These symptoms may appear either in the acute or chronic form, although they are not separated by well-marked pathological differences, and the only guide is that the latter more generally are to be seen as the effect of living for a time upon bread made from diseased grain, and is more likely to affect a number of persons than a single individual.

The action of ergot is antagonized by the exhibition of nitrite of amyl, which possesses the property of dilating the arterial capillaries, and possibly also by glonoin and by all those remedies which cause depression as a secondary effect—such as aconite, veratrum viride, tobacco, and lobelia. After the immediate difficulty has been met and overcome, potassium iodide, corrosive sublimate, and the diffusible stimulants—like carbonate and iodide of ammonium—should be administered, while the persistent use of oxygen gas is to be commended. Cerebral symptoms may be avoided, for a time at least, by compelling the patient to retain the recumbent position. The remedies which can be relied upon as synergists are cold, digitalis, and electricity, when administered in such a manner that the primary action favors the contraction of the minute blood-vessels; belladonna, too, when taken in such quantity as to produce a degree of narcotism, will be found to favor the action of ergot.

The antidotes are tannin and stimulants, besides the inhalation of oxygen to prevent paralysis of respiration, which is the mode of death from ergotism.

Absorption from the stomach, or its use hypodermatically, will produce the full physiological effects of the drug, although the history of the epidemics which have occurred would lead us to suspect that want of proper food may have something to do with their development, as ordinarily no bad results attend the exhibition of medicinal doses.

Of the active principles, sphacelinic acid appears to be the most characteristic of ergot in its effects upon the uterus, as well as upon the arterioles, but the active principle, cornutine, is entitled to a share of credit, as its action upon the blood-vessels is very decided. Ergotinic acid, when given alone, reduces the blood-pressure, showing that in its crude form ergot is a complex product. Ergotin, or Bonjean's ergotine, is a product now on the market, and that is the preparation generally referred to, although it is liable to be inert from faulty methods of preparation, and as these are defects which are at all times unavoidable, due allowance must be made in the case of adverse reports upon any preparation. The perfection of the product is always to be considered, but this is especially demanded when the hypodermatic method is to be adopted.

Neither ergotinic acid nor ergotinine appear to possess the property of influencing or inducing uterine contractions. The former causes very decided nervous symptoms, while the latter can be removed from ergot without apparently affecting its properties. The action of ergot preparations will therefore depend upon the amount of sphacelinic acid and cornutine they contain, which leads to the observation that physicians will do well to confine themselves to assayed preparations until the different active principles have been fully studied and placed on the market.

Ergot has been variously classed as a stimulant and oxytocic, and its general action has long been regarded as an emmenagogue and ecbolic, but later knowledge of diseased conditions has greatly widened the field of its usefulness, and there are other indications for this drug than to cause contraction of the uterus and check hæmorrhages. It causes dilatation of the pupil; acting upon the blood-vessels as a styptic, it is closely connected with astringents, which nearly all coagulate albuminous substances.

The nervous system is distinctly affected by preparations of ergot, although Ringer asserts that its action upon the heart is not due to the effect upon the vagus (inhibition), but to its direct action upon the cardiac muscle. Brunton has observed that the circulation in the frog's heart is not always attended with the same symptoms, although he believes that slowing and diastolic arrest are due to the action of ergot on the inhibitory apparatus. This slowing of the heart, with less powerful contractions, and final arrest in diastole, he thinks, is due to the depressing action of the drug on the motor ganglia of the heart. He suggests also the probability that ergot affects the heart muscle as it does the arterioles, and that, in addition thereto, inhibition is effected through the vagus acting upon the cardiac ganglia. The investigations of this industrious author have been very carefully conducted, and will be of immense value to those who may wish to undertake experimental researches on their own account. For convenience the following observations are selected: Cornutine, he says, is the principle which is concerned in the stimulation of the vaso-motor center, causing a rise in blood-pressure, but, with due respect, it is suggested that the word irritant would better express the action which this drug is supposed to have upon the vaso-motor center, and the context is a sufficient indorsement of the exception made, as he goes on to say that it is very doubtful whether these nerves are stimulated by drugs, as he has not been able to demonstrate whether the action is upon the terminal filaments or in the muscular walls. On the whole, it is accepted that the function of the motor nerves is somewhat heightened, while the sensory nerves as well as the spinal cord are paralyzed.

Much controversy has arisen regarding the action of ergot upon the circulation, and it has been proved experimentally that ergot causes contraction of the smaller arteries by acting on their muscular walls, thus increasing the systemic blood-pressure. The facts can not longer be denied that ergot affects more especially tissues that present excessive vascularity—as in the gravid uterus, thyreoid enlargement, and hypertrophy of the spleen and of the prostate. Not only is there cerebral and spinal anæmia, with blanched appearance of the face and coldness of the skin, but there are other evidences of arterial anæmia and consequent venous dilatation, with distention of the abdominal vessels—a condition which interferes with the regular distribution of the drug throughout the system, and which should be avoided when the administration is to be long continued. It is readily admitted that ergot causes gangrene by diminishing the caliber of the vessels and obstructing the circulation, but the method by which this object is secured has long been a bone of contention. It will therefore not be considered out of place should the matter be referred to here as viewed from the clinical standpoint.

Bartholow says the notion that ergot causes contraction of the arteries by stimulating the vaso-motor system and its muscular apparatus has long been entertained, and he is

disposed to adopt Wernich's theory, announced in 1870, that the arteries become smaller by passive collapse, by reason of a deficient supply of arterial blood. He reasons that, as active movements of the muscular fibers of the intestines and uterus may be induced by arterial anæmia, these increased peristalses and uterine contractions must be due to "diminished cardiac energy, dilatation of the veins, and arterial anæmia," thus eliminating the influence which has heretofore been supposed to rest with the sympathetic system. The explanation is complicated and difficult to comprehend, and, besides, it starts the student on a line of investigation with a view to determine the cause of this sudden change of base. Would it not be well in this case to assume that the nearest approach to the facts lies in assuming that ergot so affects the sympathetic nervous system that control over the muscular fibers of both intestinal canal and uterus is suspended, and that, possessing inherent contractile properties, these muscular fibers contract, the result being arterial anæmia? If this theory is adopted, it follows that all unstriped muscular fiber wherever found in the human body is similarly affected; and the proposition is substantially true.

This explanation apparently is confirmed by the use of the drug, and is sufficient to account for the contradictory statements which have been made regarding certain preparations, as well as the varied effects which have been noted by different observers. Thus in the case of pulmonary hæmorrhage, or post-partum hæmorrhage, the administration of a drachm or more is generally followed in due time by a subsidence of all the dangerous symptoms, and the preparation is pronounced good; but, should the emergency again occur in the course of a few hours, a repetition of the dose is apparently useless, and the drug is condemned. The difficulty here lies not so much in the preparation as in the method of administration. The initial dose produces arterial anæmia at the same time that it causes a cessation of the hæmorrhage, but arterial anæmia, with its attendant constriction of the arterioles, prevents the drug from reaching the affected tissues in sufficient quantity to produce an effect commensurate with the amount taken the second time. The first dose practically destroys itself by causing arterial anæmia with dilatation of the abdominal veins, and the second dose soon reaches the same pocket. Should the patient insist upon maintaining the upright position, cerebral symptoms will not long be delayed, and if continued for a length of time, distinct physiological indications of ergotism will be manifested.

These symptoms resemble in some respects the conditions which attend upon somatic death before cellular death has taken place. An illustration is found in the emptied cardiac cavities, the contracted and bloodless arteries, and in the involuntary contractions which occur in the parturient womb, which has been known to expel the child *in utero* after the death of the mother; and yet no one has thus far interpreted the phenomena above described as being due to stimulation of the sympathetic system, nor has it been pointed out as an illustration of passive collapse of the arteries. The absurdity of these propositions furnishes no inducement for argument, and for the same reason the "temporary hypothesis" regarding inhibition, so far as it relates to ergot, should be discarded.

The benefits to be derived from the appropriate exhibition of small doses of this drug, in view of the foregoing propositions, are now readily understood; the explanation is simple, and apparently the demonstration is complete. When a comparatively small quantity is introduced into the system, and the dose frequently repeated, the nerves controlling the caliber of the blood-vessels are constantly under its influence; their power over the muscular fibers is suspended or held in abeyance, and not until considerable time has elapsed will pronounced general arterial anæmia take place; the operation of the drug is constant, the effect more permanent, and likewise more certain, when small doses are administered. The deduction is not warranted, however, that large doses are always contra-indicated; on the contrary, there are times when it is desired to get the immediate effects of the drug, and in such emergencies a drachm or more may be given with the expectation that good results will attend its use, providing the stomach does not rebel.

The true position of ergot in its entirety, with reference to its paralyzing action upon respiration, in the light of this explanation can not fail to be appreciated. Embarrassment of respiration naturally attends upon diminished blood-supply, a condition which involves the systemic to an equal extent with the pulmonary circulation. Defective internal respiration becomes a factor of paramount importance, and the attending phenomena are thus rendered explicable, and to a certain extent conclusive, regarding the position assumed. It will be noticed that I have not in this discussion taken into consideration the special action of the respective substances which have been isolated and are now recognized as active principles, and in explanation it should be added that for the most part they may be looked upon more as laboratory curiosities than as therapeutic agents, because at present they are not produced in sufficient quantity to enable the physician to supply his patients with them. Doubtless the time will come when their specific uses will be of great benefit to the medical profession, but until material advances have been made in our methods of pharmacy we must be satisfied to continue the use of the crude drug.

A study of the effects of large doses, medicinal doses, and small doses would be an interesting subject, but so much has already been said that it is believed this matter may with propriety be omitted. Whoever will consider candidly what has already been said needs no caution as to the proper methods for using this remedy so far as it affects the circulation. However, a few words may be added: that it contracts the arterioles like digitalis; that, like digitalis, it is a vascular sedative, and lessens the flow of blood through the vessels (arterioles), and for this reason it has been successfully used in controlling local inflammatory action. Acting thus upon the blood-vessels, ergot may be employed as a styptic, and is therefore closely allied to astringents. The slowing of the heart follows upon the increased amount of work the organ is called upon to perform in forcing the blood through the contracted blood-vessels

and for the same reason the rate of the pulse is lowered, while the arterial tension is considerably raised. The effect thus produced upon the brain may develop syncope, or the presence of the drug in the tissues may be sufficient to cause symptoms of narcotism.

Respiration is slowed, and, as has already been stated, death takes place from paralysis of this function. Ergot in decided doses lowers the temperature, and, when long continued, the general action simulates in some respects certain forms of disease.

As mentioned above, the action of ergot is manifested upon the involuntary muscular fibers throughout the body, and is not, as was long supposed, confined to the muscular fibers of the uterus; other organs—as the heart, the kidneys, the liver, and the muscular walls of the intestine—are also affected, and, when given hypodermatically, may cause inco-ordination, anæsthesia, and paralysis.

A noticeable feature in connection with the development of ergotism is the fact that functional activity of the digestive system is greatly increased, and the appetite becomes ravenous; this condition may be accounted for, in part at least, by the determination of blood to the abdominal veins, showing that it is the physical rather than the nervous system which is affected. Peristalsis is increased, and there is an increased secretion from mucous surfaces, but small doses, even when long continued, present no physiological derangements except as regards the face. Large doses set up gastro-intestinal irritation. So far, no investigations have been made to determine its effect upon the composition of the blood.

In addition to what has been said, the action of ergot upon the genito-urinary system may be summed up in a few words. By its exhibition, contractions of the muscular fibers of the uterus are set up different from those which occur normally by reason of their tonicity, and to express this peculiarity the word tetanic has been adopted. Brunton suggests that this action may be partly due to the influence of the drug upon the uterine center in the spinal cord. By reason of the property just mentioned, ergot has been classed as a direct emmenagogue. The mode of action of ecbolics is still undecided, although there is no question but that ergot is one of the first. The urine is increased in amount, but this can not be accepted as an indication for its use in the treatment of diabetes insipidus, a condition which probably depends upon a relaxed state of the renal tissues, which ergot promptly overcomes. There is reason to believe also that the muscular fibers of the bladder respond to the influence of this drug.

1910 Arch Street.

NEW TESTS FOR BINOCULAR VISION.*

By J. A. LIPPINCOTT, M. D.,
PITTSBURGH, PA.

Tests for binocular vision are of two classes—1, those for determining the presence or absence of uniocular blindness; and 2, those for establishing the existence or non-existence of binocular single or stereoscopic vision. The former class includes all the methods of preventing the sound eye from seeing—*e. g.*, placing a strong convex glass in front of it, as suggested by Harlan,* or a strong concave glass, as mentioned by Juler,† or rendering certain letters of a word invisible, as in Snellen's‡ test, etc. This class also includes the examination of the pupil reflexes direct and indirect. The second class includes Hering's test and the temporary strabismus test with a prism, as well as the various tests with the stereoscope, etc.

The tests which I venture to present for your consideration to-day belong to the second class. Like other tests of this class, they may, of course, when they elicit positive results, take the place of tests of the first class, and so may be of use in the detection of malingering. If, on the other hand, the results are negative, they demonstrate only the absence of binocular single vision, and not the presence of monocular blindness.

In 1875 Dr. Wadsworth# reported a case in which a $-\frac{1}{13}$ cyl., axis vert., before the left eye, and $+\frac{1}{13}$ cyl., axis 45°, before the right, produced an apparent convergence of parallel lines toward the left side. On November 3, 1888, the *Journal of the American Medical Association* contained an article by Dr. H. Culbertson in which he referred to phenomena similar to that observed by Dr. Wadsworth. In March, 1889, I published in the *Archives of Ophthalmology* an article on The Binocular Metamorphopsia produced by Correcting Glasses, in which I gave the results of a large number of observations and experiments. These results, or rather those of them that have a bearing on the purpose of the present paper, may be briefly restated as follows:

1. A + spherical placed before one eye makes the corresponding side of a rectangle appear higher than the other side.

2. A − spherical makes the corresponding side appear lower.

3. A + cyl., vertical, *increases*, whereas a + cyl., horizontal, lessens the apparent height of the corresponding side.

4. A − cyl., vertical, lessens, whereas a − cyl., horizontal, increases the apparent height of the corresponding side.

---

* Read before the American Ophthalmological Society at its twenty-sixth annual meeting.

* *Trans. of the Amer. Ophthal. Soc.* for 1882, p. 400.

† *Ophthalmic Science and Practice*, Philadelphia, p. 227.

‡ Snellen's test is to be considered as a test rather for the absence of monocular blindness than for the presence of binocular single vision, because, as ordinarily applied—viz., with one eye covered with a colored glass—if all the letters are visible, we know that both eyes see, but we do not know that they see in unison, since the covered eye may no longer fix. If, on the contrary, we cover one eye with a glass of one and the other eye with a glass of the other complementary color, and if the word still remains visible, we demonstrate the presence not only of *binocular*, but of *binocular single* vision.

The test just alluded to, and the various prismatic tests, with the exception of the one to be mentioned in a subsequent foot-note, are, strictly speaking, tests for binocular single, but not for stereoscopic vision, the latter involving the element of depth or estimation of distance, in which the varying degree of convergence of the optic axes plays the leading *rôle*. The distinction may, however, be regarded as theoretical rather than practical.

Trans. of the Amer. Oph. Soc. for 1875, p. 342.

5. A + cyl., axis pointing upward and outward, before either (and still more decidedly before each) eye makes the top of a rectangle appear narrower than the bottom, while if the axis point upward and inward the top appears wider.

6. — Cylinders, axes upward and outward, increase, whereas those with axis pointing upward and inward lessen the apparent relative width of the top.

7. Binocular vision is necessary for the production of optical metamorphopsia. Hence the lens must not be so strong as to make the image sufficiently blurred to be incapable of fusion with that formed by the other eye, for in that case the blurred image is suppressed mentally and monocular vision thus practically established.

At the last meeting of this society, Dr. Green* suggested the most plausible explanation yet given of the appearances above described, although this explanation seems unsatisfactory in some respects.

The appearances can be elicited in the case of all persons—emmetropes, ametropes, or anisometropes. The only *sine qua non* is the possession of binocular single or stereoscopic vision. Such being the case, it has occurred to me to employ the phenomena of optical metamorphopsy as stereoscopic tests.†

In applying these tests, I usually hold a + 2 cylinder, vertical, before one eye with one hand, while with the other I hold up a twelve-inch-square card at the ordinary reading distance, and then ask which of the two sides is the higher. The answer is generally pretty prompt and decided. I then quickly put the card to one side, turn the axis of the cylinder to the horizontal, and again hold up the card. The side, which in the first instance appeared higher, now appears lower than the other. If I wish to confirm the results obtained with the + cylinder, I employ a — 2 cylinder, first with the axis vertical, making the corresponding side appear lower, and then with the axis horizontal, producing the contrary effect. If I wish to make assurance doubly sure, I make the top of the card appear wider or narrower than the bottom by holding either one or two cylinders with axis oblique before the eyes, etc.

The advantages which may be claimed for these tests are their variety and their simplicity. They are stereoscopic tests with the stereoscope left out. The unsuspecting patient may in the space of a few minutes be examined and cross-examined again and again with no more extensive apparatus than a rectangular card or book and two or three lenses from an ordinary trial case.

Besides enabling the examiner to dispense with the stereoscope and its attendant paraphernalia, a signal advantage is that we have the patient more completely under control. We can better observe him than if his eyes are hidden behind the eye-pieces of the stereoscope, and can thus effectually guard against any experiments which he may, if of an investigating turn of mind, desire to try as to the effect of closing one eye. Besides, the changes can be rung with such rapidity as to confuse the most accomplished malingerer if he actually possesses binocular single vision.

I think it important on practical as well as on theoretical grounds to have a test for stereoscopic vision which can be quickly and easily applied. In refraction work, for example, we are sometimes in doubt as to the propriety or necessity of correcting both eyes, owing to the patient's inability to decide whether or not he sees better with both eyes than with one. In such cases we may be aided by knowing whether the stereoscopic faculty is present. To illustrate:

Case I.—E. P. A. has S. R. E. = 8 CC.; L. E., do. R. E. — 13 — 4 c., 20°, S. = 20/Lx; L. E. — 12 — 4 c., 165°, S. = 20/Lx. Reads best with R. E. — 7 — 3·5 c., 20°; L. E. — 7 — 3·5 c., 165°; P. D. 62 mm. With these glasses a vertical prism develops at twenty feet distance esophoria = prism 5, and at reading distance exophoria = prism 6. In near fixation each eye, on being covered, swings out about two mm. With both eyes corrected for reading, patient can not positively state whether or not the two eyes are better than one. Sometimes they seem better and sometimes not. The metamorphoptic test shows that stereoscopic vision is possible, though not constant. Hence I corrected both eyes in the expectation that the binocular impulse, although now feeble, may in time be developed and strengthened.

Case II.—Dr. A. M. N., aged fifty-eight: S. R. E. = 20/C +· With + 1·25 + 1 c., 110°, S. = 20/xx —; L. E. emm. S. = 20/xx. Reads best R. E. + 4. + 1 c., 110°; L. E. + 3. Thus fitted, patient could not say whether or not the right eye helped vision. But metamorphopsia was present, and therefore I corrected both eyes.

Of course I do not mean to say that the possession of stereoscopic vision always makes it desirable to correct both eyes, because every one knows that there are cases of anisometropia which, although showing undoubted stereoscopic vision (and indeed because of it), will tolerate the correction of only one eye. On the other hand, the absence of stereoscopic vision is not an infallible indication for correcting only one eye, because we, in rare instances, find persons who use one eye for remote and the other for near vision.

On one occasion the stereoscopic test led me to discover a condition which I had previously overlooked.

Case III.—Miss C. L. F., aged fifty-five: R. E. (operated upon for cataract, October, 1887) + 11 + 2 c., hor., S. = 20/xx —; L. E. (operated upon October, 1888) + 12, S. = 20/xxx. At the time I was making some experiments with regard to metamorphopsia in aphakial eyes, and I found that in this case metamorphoptic phenomena could not be elicited. On seeking the cause, there was discovered a slight deviation upward of left eye = prism 4. On adding to her reading glasses the appropriate vertical prism, stereoscopic vision was promptly established, and reading was now better accomplished with both eyes than with one.

Not long ago I was asked by a man who had been operated upon for cataract, whether he could go back to his trade of bottle-maker. His vision is unusually good. R. E. + 6·5 + ·75 c., 62°, S. = 20/xx +; L. E. + 6·5 + 1·5 c., 172°, S. = 20/xii. Before answering his question, knowing how important it would be for him to estimate distance

* *Trans. of the Amer. Ophth. Soc.* for 1889.

† The apparent concavity (*Krümmung*) and convexity (*Wölbung*) produced in a plane surface by prisms, bases out or in, explained by Nagel in Graefe u. Saemisch's *Handbuch*, Bd. vi, S. 366, answer the same purpose.

correctly, his stereoscopic vision was tested and found perfect. I unhesitatingly assured him that he would have no difficulty. He has since told me that he can now work better than ever. This is doubtless owing to the fact that, before the cataracts developed, he must have been myopic, as may be inferred from the comparatively weak glass now required to overcome his aphakia.

In conclusion, it may be said that the tests here suggested furnish a convenient means of investigating certain theoretical questions, such as the comparative frequency of stereoscopic vision in general, and especially in anisometropia, in monocular amblyopia,* after the correction of strabismus, etc. But a discussion of these points is beyond the purpose of the present paper.

A CASE OF UTERUS BILOCULARIS UNICOLLIS.

By WARREN B. CHAPIN, A. M., M. D.

So many cases of uterine anomalies are now on record that we are enabled to classify the different forms of malformation, and have ceased to regard them as anything out of the common. The diagnosis of the existence of such malformations and their exact form is difficult, owing to the concealed location of the organ and the relative absence of distinguishing symptoms, and the occurrence of these malformations would seem of much greater frequency than the recorded cases show. I am induced to report the following case, evidently that of uterus biocularis, chiefly on account of the peculiarity of the dividing septum, which differs in form from that usually found in the bilocular uterus.

On July 14th Mrs. S., aged twenty-four years, primipara, four months pregnant, was seized with labor pains. On examination, the os was found slightly dilated, and nothing abnormal in appearance of the cervix for that period of pregnancy. Employed the usual treatment for abortion, and several days later, the secundines not having been expelled, proceeded to empty the uterus. On vaginal examination, found the os well dilated, but the uterus was apparently empty. On again introducing my finger into the uterus, found a second cavity which contained the placenta, and which was separated by a wedge-shaped septum from the cavity into which my finger had first been introduced. The course of the abortion presented no unusual features, excepting that scarcely any blood was lost. The fact that the examining finger was first introduced into the empty cavity shows how easily a mistake in diagnosis could have been made, and, owing to the retained secundines, septic symptoms set up. As may be seen in Fig. 1, the dividing septum is wedge-shaped, having its base at the fundus uteri and its apex ending crescentically at the internal os, instead of being about the same general thickness from fundus to termination, as is usual in the uterus biocularis. The gravid cavity was of about double the size of the other, with thinner uterine walls, and it had evidently pushed the septum over against the unimpregnated cavity as it increased in size. The cervical canal is common to both cavities. Fig. 2 shows the probable position of the septum before conception took place, it having assumed nearly that position since the uterus was emptied. The dotted lines in Fig. 2 show the shape of the septum as usually found in the bilocular uterus.

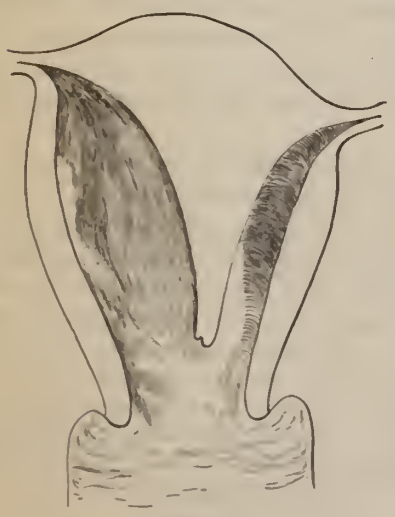

Fig. 1.

Fig. 2.

In consequence of the wedge-shaped septum, the wide-spread separation of the cavities and their lateral direction would lead to the diagnosis of uterus bicornis; but, on bimanual examination, the uterus was found to consist of a single body, which was somewhat larger than is usual at the fourth month of pregnancy. There was no separation at the fundus, and the convexity of the uterus was normal in shape, with the exception of an enlargement on one side, due to its gravid state.

Since writing the foregoing, I have delivered the patient of a six months' fœtus, which occupied the cavity I had supposed to be unimpregnated.

On August 12th, twenty-nine days after delivery of the first fœtus, the patient complained of severe pains in the abdomen and back. Her abdomen, which was nearly flat when I last saw her two weeks before, now had the appearance of the sixth or seventh month of pregnancy. She said it had suddenly grown large about a week after I last saw her.

I found the os well dilated, and a fœtal head presenting from the right cavity, the one I had supposed to be unimpregnated. The left cavity was dilated sufficient to admit my two fingers. A few hours later she gave birth to a small six months' fœtus which was still contained within the unruptured amniotic sac and surrounded by the placenta.

Subsequent examination of the uterus confirmed my diagnosis of a bilocular uterus with a wedge-shaped septum. At the first examination I was led to believe that the right cavity was unimpregnated, from the fact that my finger entered it for at least two inches without encountering a foreign body.

114 West One Hundred and Fourth Street.

---

* Better expressed by "anisopia," suggested by Dr. Ryder to imply inequality of visual acuity in the two eyes.

Rush Medical College.—The chair of medical practice in the Rush Medical College, Chicago, made vacant by the death of Professor J. Adams Allen, is said to have been offered to Dr. Henry M. Lyman, formerly professor of chemistry and of diseases of the nervous system in the same institution. Dr. Harold N. Moyer has been elected to the professorship of physiology.

THE

NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by D. APPLETON & Co.

Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, SEPTEMBER 27, 1890.

ERRORS IN THE DIAGNOSIS OF INFECTIOUS DISEASES.

In many cities there exists to a greater or less extent a feeling of jealousy between the medical officers of hospitals and those whose practice lies among the class of people who frequent such institutions. A great deal of this feeling arises out of differences of opinion as to the diagnosis of infectious disease. For instance, a child has a sore throat, the physician called in has to make a rapid diagnosis on very doubtful symptoms, for he must protect the other children, and to wait until he is quite sure about the throat means that he is to wait until diphtheria has time to fasten itself upon the others. With much difficulty he persuades the mother to take the child to the hospital, where a few hours later she is told that the child has not diphtheria at all, or that it has scarlet fever, the rash having become developed in the mean time. Possibly the hospital doctor may have more experience, but as a matter of fact he is generally young, while the outside man is commonly his senior, and the bitterness of the difference of opinion is intensified. We do not mean to say that in all instances the hospital physician is right, but it is plain that he acts at a great advantage. The case is more advanced when it reaches him and he is not obliged to act upon the very spur of the moment. The patient can be put into a general ward for observation for a few hours and additional advice can be obtained.

In the *Glasgow Medical Journal* Dr. Russell, the well-known health officer of that city, deals with the subject of errors in the diagnosis of the infectious diseases. To begin with, typhus and typhoid fevers very commonly are mistaken the one for the other, and both for other diseases. In a localized outbreak of typhus cases of this disease were found by the health officers to have been diagnosticated, the majority as "enteric," and the initial case had been treated as inflammation of the lungs. Of 1,499 consecutive patients sent into the Belvidere Hospital as suffering from infectious disease, 114, or 7·6 per cent., did not suffer from the particular affection for which they had been sent in, and of those 114, no fewer than 85, or 5·7 per cent. of the whole number, had no infectious disease at all. Mistakes in scarlet fever, measles, and whooping-cough are few. In only three per cent. of the scarlet-fever cases was the diagnosis wrong, and one per cent. only of the patients had no infectious disease. Errors were excessive in enteric and typhus fever, and also in diphtheria. Seventeen per cent. of the persons sent in with a diagnosis of enteric fever had not that disorder, and most of them had no infectious disease at all. Of the certificates of diphtheria, twenty-four per cent. were wrong and about twelve per cent. of the patients had no infectious complaint. Forty-four per cent. of those said to have typhus were free from that fever, and half of that proportion did not require hospital treatment. Of the forty-two cases erroneously designated enteric fever, fourteen were inflammation of the lungs, five simple diarrhœa, four disease of the brain, five various chronic affections, and four typhus; the remaining ten patients were absolutely non-febrile. Of the sixteen cases wrongly certified as typhus, three were pneumonia, one was purpura, and one alcoholism. Three patients had no obvious disease, and eight suffered from typhoid fever. When the diagnosis of diphtheria was erroneous half the patients had scarlet fever and the other half simple inflammation of the throat. In fifty-eight cases the cautious diagnosis of "fever" was given; twenty-four of these turned out to be typhoid, nine typhus, six scarlet fever, three measles, and one whooping-cough. Of the remaining fifteen, lung inflammations accounted for nine and three were non-febrile.

These figures afford food for very serious reflection. The protection of the community from disease depends upon its prompt recognition, and that can not be effected unless those intrusted with this public duty are specially trained for the purpose. Dr. Russell's report has been followed in Great Britain by a cry for the better instruction of students in the diagnosis of infectious disease, and it would be well if in this country we turned our attention in the same direction. It is not an exaggeration to say that ninety-nine per cent. of those who are graduated in our colleges are devoid of any practical knowledge relating to the recognition of infectious diseases in their early stages, and it is quite possible that a young graduate might in his first year's work stumble upon an initial case of diphtheria, typhoid fever, or scarlatina, the prompt handling of which might save the community all the miseries incident on sickness and death from that disease.

A SURGEON'S SERMON ON HOSPITALS.

It is not often that we are called upon to record the fact that one of our profession has been addressing the public directly. Appeals for aid toward our great charities are generally left for the lay workers connected with such institutions. Hospital Sunday services were held in London on the 15th of June, and a large amount of money was collected. No doubt many eloquent sermons were preached at the hundred or more churches at which this special collection was made, but we venture to say that the best sermon preached for the hospitals came, not from the pulpit, but from the platform at the public meeting summoned by the Lord Mayor for the purpose of promoting the welfare of the hospitals of London by means of the Metropolitan Hospital Sunday Fund, and the preacher of that sermon was Mr. Jonathan Hutchinson, a man who has honestly earned the love and respect of all members of our profession. In the selection of Mr. Hutchinson the hospitals gained the services of an eloquent and earnest pleader, and any one who loves his fellow-man must be the better for reading his address. Mr. Hutchinson spoke of himself as one who had been a long time behind the scenes, and who knew much of the workings

of not a few hospitals, and he solemnly declared his belief that no institutions in the world were on the whole better managed than the hospitals of the British metropolis. He then dealt with the various charges brought against modern hospitals, some of which he believed were to a certain extent true, but to an insignificantly small extent, and he showed how some of the charges neutralized others. Thus, it was said that out-patients were hurriedly examined and seen by deputy, while others declared that the attractions of the out-patient department were so great that people comparatively well to do deserted their family advisers, and thus the medical profession was defrauded. But abuses such as the last named affected chiefly the special hospitals, and therefore the consultant suffered and not the general practitioner.

The definition of a modern hospital which best pleases Mr. Hutchinson, and which he likes to keep constantly in mind, is that it is an institution for the prevention of orphanage. Not that all or nearly all the maladies treated entail danger to life, nor that all the patients are parents, but a large proportion of hospital practice does concern those who have others dependent upon them, and we may suitably recognize degrees of incapacity short of actual death, for the loss of a limb or an eye or a permanent impairment in health may easily entail on a man's family calamities little short of what would have followed his death. Such a definition helps us to some adequate conception of the real value of such institutions and places medical charity in the position which it really ought to occupy —that of the foremost of all forms of beneficence. Hospitals are the schools in which medical science is cultivated and from which those go forth who spread its benefits all over the world. Within recent years some diseases have been nearly exterminated, the ratio of mortality from nearly all has been greatly diminished, and the average duration of human life has been definitely increased. We are at war with death, not the divine ordinance of death, which we accept thankfully as one which favors the progress of our race, but with death in its premature and irregular forms. We wish to prevent and remedy the disabilities of life, the disqualifications for usefulness in its duties and enjoyment of its happiness. We wish to prevent orphanhood in all forms and degrees.

Some persons think that it would be better if hospitals were supported by the state, but with them the speaker did not agree. Free giving was an education involving self-education. The act of giving might become by custom the source of one of the highest forms of pleasure of which our natures were capable; and no such gratification attended the payment of a tax or rate. If, however, we rejected a state-imposed tax, Mr. Hutchinson proposed a self-imposed tax on health in its place. Those who had to bear the sufferings of illness should not be made to pay for it. As we valued the possession of sound lungs, of strong limbs, of unimpaired eyesight, of a face and figure which, free from deformity and defect, permitted of our mixing with our fellows with mutual pleasure, so let us measure the contributions which we made for the help of those to whom one or other of these blessings was denied. The heart's sympathies depended almost wholly upon our power of realizing what suffering really was. An unimaginative person could not, for example, realize what it was to be blind. He could walk and run, and he never troubled himself to imagine what it was to be lame. The imaginative faculty was, then, the highest of all human endowments, since it was at the bottom of all generous emotions. Let any one who was conscious of lack of sympathy with the afflicted go for a week to his usual city vocations with a black patch covering one eye; let him wear for one day a wooden leg, a truss, or a spinal apparatus, and he would find his fellow feelings for those in need of such appliances vastly increased. Let him choose some leisure day in the country in bright spring and resolutely for twenty-four hours keep a bandage placed over both eyes. His would be a hopeless case if the next morning he did not send a contribution to the hospital. The speaker concluded his address with an earnest appeal to the young men and maidens who, in possession of vigor and beauty, regarded the future of life with unclouded hope, to those in middle age who were enabled to rejoice in their own or their children's health, and to those who, although now old, could look back with thankfulness on the events of life.

MINOR PARAGRAPHS.

THE PROFESSIONAL MARK OF BAKERS.

Dr. G. Ranzier, in a paper in the *Gazette hebdomadaire des sciences médicales de Montpellier*, describes a professional mark that is nearly always present in Montpellier bakers, and that possesses a medico-legal interest. His attention was first called to it by a typhoid-fever patient, a baker, who had on the dorsal surface of the articulation of the first and second phalanges of each finger a large, round callosity covering the width of the finger. It was a hardening of the epidermis without participation of the deeper structures, and almost disappeared during the two months' treatment of the case. When questioned regarding the callosities, colloquially known as *bastets* or *coussinets*, the boy stated that bakers always had them. This statement was subsequently verified. The repeated shock of the flexed fingers against the dough in kneading produces the callosities. Where the kneading is done mechanically, of course, such stigmata will not be found. The author states that neither Tardieu, Max, nor Vernois, in their publications on the professional stigmata, refers to this mark of the baker that may be of medico-legal value.

MR. HUTCHINSON'S TREATMENT OF RINGWORM.

Mr. Jonathan Hutchinson gives, in his *Archives of Surgery*, the prescription upon which he has "settled down in tolerable content" for the treatment of ringworm, after having tried a great variety of remedies without equal satisfaction. He relies chiefly on chrysophanic acid. He orders as a wash for the scalp one drachm of Wright's liquor carbonis detergens to the pint of hot water. Twice a week the scalp should be well washed with this, and all scales and crusts should be removed. The hair is cut close or shaved. The chrysophanic-acid ointment contains a drachm of chrysophanic acid, twenty grains of ammoniated mercury, a drachm of lanoline, six drachms of benzoated lard, and ten minims of liquor carbonis detergens. This ointment is to be rubbed in more or less freely, according to its effects, night and morning, or latterly every night only.

The cure will be slow probably, and the secret of success consists in the patient continuance of the same remedy. To those who persevere he promises recovery; it is only the impatient who are disappointed. He has no faith in the rapid cure of ringworm.

THE STATE MEDICAL SOCIETY OF ARKANSAS.

Acting in accordance with the advice given by a recent president, Dr. Orto, the society has established a monthly journal. The first number is dated July, 1890, and contains, among other matter, Dr. Orto's presidential address, a number of papers read at the fifteenth annual meeting, and the minutes of the meeting. The journal is edited by Dr. Lorenzo P. Gibson, of Little Rock, under the supervision of a board of trustees consisting of Dr. P. O. Hooper, Dr. J. H. Southall, Dr. J. A. Dibrell, Dr. Zaphney Orto, and Dr. W. B. Lawrence. It presents a creditable appearance, and will doubtless aid materially in furthering the society's work.

THE FRENCH LAW REGARDING TWINS.

According to the *Medical Press and Circular*, a law passed years ago in France regards the last-born as the eldest in the case of twins. Consequently, when both of them survive and both are boys, on reaching manhood the second-born is required to serve in the army, for he has been legally adjudged to be the eldest. The reason for this is said to be that by some extraordinary calculation the medical men who were consulted at the time the law was framed came to the conclusion that the last-born of twins was always the first conceived.

THE MIDWIFERY DISPENSARY.

We have already spoken in commendation of this institution, and we are glad to learn from its published statement, dated July 18th, that it has afforded medical aid to a large number of applicants, and given instruction to thirty-one students, although it has been in operation considerably less than a year. The dispensary is exceedingly well managed, and we doubt not that it will continue to grow in professional and public esteem.

THE PARIS POLICLINIQUE.

An institution entitled the *Policlinique de Paris* has been opened at No. 28, rue Mazarine, for the purposes of furnishing medical aid to the poor and of giving practical instruction to medical students. From the information given in its journal, the *Annales de la Policlinique de Paris*, we judge that it closely resembles the post-graduate teaching institutions of America.

THE ASHEVILLE MEDICAL REVIEW.

This is the title of a new monthly journal which gives as its reasons for existence the purpose of keeping the profession informed as to the advantages of Asheville as a resort for invalids and that of supplying the requirements of western North Carolina and eastern Tennessee for a local medical journal. It contains the official reports of the proceedings of the Buncombe County Medical Society. It is edited by Dr. Frank T. Meriwether and Dr. H. Longstreet Taylor.

ITEMS, ETC.

The New York State Preliminary Examinations.—The examiners delegated by the Board of Regents of the University of the State of New York to examine persons entering upon the study of medicine, under the new law, began their work on Tuesday in New York, Brooklyn, Buffalo, Albany, and Syracuse. The candidates were examined in arithmetic, geography, grammar, English composition, United States history, physics, and physiology. The following was the examination in geography:

1. Define latitude and longitude and tell how each is reckoned. 2. Mention the grand divisions of the globe in the order of their importance, and give a reason for your answer. 3. What is a sea, a strait, a watershed? 4. Describe the two principal forms of government. 5. Draw an outline map of the United States and locate upon it two principal mountain chains and the Mississippi River and three of its principal tributaries. 6. Mention in order the States in which you would travel, by direct route, from Chicago to Washington. 7. Mention in the order of their size the largest three cities of the United States, as determined by the census of 1890. 8. Mention three cities in the State of New York where law or medical schools are located. 9. Which of the New England States, if any, does not engage largely in manufactures? What is its principal industry? 10. Mention in order the cities on the New York Central Railroad between Buffalo and Albany. 11. What States of Central America have recently been at war? 12. Describe the vegetable and mineral products of South America. 13. What country of South America recently changed its form of government, and what was the change? 14. Write the names of the following countries, and after each give its form of government and capital: England, Italy, France, Germany. 15. In what countries would you travel in going by the shortest route from Madrid to St. Petersburg? 16. What countries border on France? 17. Give the names of the largest four rivers of France and tell into what each empties. 18. Mention two exports of the empire of Japan. 19. Describe the Congo River, telling where it rises, in what direction it flows, and into what it empties, and give the name of the explorer who first traced it from its source to its mouth.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending September 23, 1890:

DISEASES.	Week ending Sept. 16.		Week ending Sept. 23.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	57	13	39	13
Scarlet fever	39	1	17	7
Cerebro-spinal meningitis	1	1	1	0
Measles	32	3	45	6
Diphtheria	47	19	42	17

The New York Polyclinic.—It is announced that this institution will exclude from its matriculates in future all persons who are not graduates of regular medical colleges or, having attended one or more courses of lectures at such a college, have a legal permit to practice.

The Chicago College of Physicians and Surgeons.—Dr. James A. Lydston, late chief of the eye and ear department of the Pension Bureau at Washington, has been elected professor of chemistry in the college.

Changes of Address.—Dr. J. Conger Bryan, to No. 357 West Fiftieth Street; Dr. Egbert H. Grandin, to No. 36 East Fifty-eighth Street.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending September 20, 1890:*

Olcott, F. W., Passed Assistant Surgeon, ordered to the U. S. Steamer Alert.

Society Meetings for the Coming Week:

Tuesday, *September 30th:* Boston Society of Medical Sciences.

Wednesday, *October 1st:* Society of the Alumni of Bellevue Hospital; Harlem Medical Association of the City of New York; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (Stapleton), N. Y.; Penobscot, Me., County Medical Society (Bangor); Bridgeport, Conn., Medical Association; Philadelphia County Medical Society.

Thursday, *October 2d:* New York Academy of Medicine; Metropolitan Medical Society (private); Society of Physicians of the Village of

Canandaigua; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Washington, Vt., County Medical Society.

Friday, *October 3d:* Practitioners' Society of New York (private); Baltimore Clinical Society.

Saturday, *October 4th:* Clinical Society of the New York Post-graduate Medical School and Hospital; Manhattan Medical and Surgical Society (private); Miller's River, Mass., Medical Society.

Letters to the Editor.

"PINK-EYE."

New York, *September 15, 1890.*

To the Editor of the New York Medical Journal:

Sir: In your issue of September 6, 1890, is a letter relative to pink-eye over the signature of John E. Weeks, M. D.

Your correspondent wishes to notice my article which appeared in your issue of June 28, 1890, in order to correct what he is pleased to denominate "some errors."

The paper published in your Journal was read before the New York County Medical Association. The aggrieved gentleman was present and full opportunity was given him to reply to my criticism on his work. Before writing my paper, being desirous of doing full justice, I wrote asking your correspondent for his latest reprint on the subject of pink-eye, and for the list of all those observers who had noticed his experiments in print.

I made this statement in my paper: "No one has, as far as I am aware, repeated his (your correspondent's) experiments, nor has any one essayed to make an analysis of the evidence he has furnished."

In reply to this your correspondent refers me to an article by Kartulis in the *Ctrbl. f. Bact. u. Parasitenk.*, p. 289, 1887, in which he says I will find a full confirmation of the results previously arrived at by him. I have not by me the letter in which your correspondent kindly sent me the bibliography of pink-eye, but I am sure this citation was not among the others. In the publication above referred to I find an article by Kartulis, of Alexandria, on the Ætiology of Egyptian Catarrhal Conjunctivitis. Kartulis, without giving in detail his methods, simply states that he found a bacillus in this disease, and simply gives some slight description of it. In so far as it is a bacillus and is found in the eye of catarrhal conjunctivis, I am willing to admit that it bears some likeness to the so-called "bacillus Weeksii." The other marks which it possesses do not, in my opinion, strengthen the claims of your correspondent. Kartulis observes: "It is an important question whether our (Ger., *unsere*, meaning his own) bacilli are identical with those found by Leber, Kuschbert, and Neisser in xerosis of the conjunctiva."

He further remarks that these observers discovered in this affection micro-organisms similar to those of mouse septicæmia.

Your correspondent, in his reprint from the *Med. Record* of May 21, 1887, refers to a bacillus observed by Koch in Egypt in cases of catarrhal conjunctivitis, and opines that it is probably the same that he himself has described. Kartulis refers to this discovery of Koch, and says that the bacillus of Koch resembles that of mouse septicæmia in size, form, and situation.

Your correspondent states that Dr. Knapp showed him some specimens of microbes obtained from the deposits about the teeth in one case and from a corneal ulcer in another that in form resembled the small bacillus which he claims is the pathogenic microbe of pink-eye. Now, Kartulis thinks it a weighty question whether or not the bacillus he describes is identical with that of xerosis conjunctivæ, and he finds a distinct likeness between Koch's conjunctivitis bacillus and that of mouse septicæmia. Your correspondent considers Koch to have described the same bacillus that he has seen, and likewise considers Kartulis to have made a "full confirmation" of his (your correspondent's) results. Absolute identity is a very difficult matter to prove. I venture the moderate opinion that absolute identity is not proved in this case. One must be forgiven for being hypercritical in matters of science.

Kartulis, whose work was published in February, 1887, does not refer to the results of your correspondent, although his first communication on this subject was made in the *Archives of Ophthalmology* in 1886. Foreign writers are great sticklers in the matter of bibliography, and it is at least surprising that so important a claim as your correspondent makes has been overlooked by Kartulis. If any one else has made a "full confirmation" of the claims of your correspondent I am unaware of it.

Quoting in substance from the work of your correspondent, I stated he was unable to make a pure culture of his bacillus. Referring to this statement of mine, he says in his letter to you: "Since writing the articles referred to above I have produced a pure cultivation of the bacillus, photographs of which have been made." At the time of reading my article I was unaware of the existence of his pure culture. He might easily have stated this to me in his letter, but he preferred to keep it silent and produce with a flourish in his reply before the society photographs which he said showed pure cultures of his bacillus.

I am quite sure he had never up to that time stated publicly his success in obtaining a pure culture. But these things had no bearing whatsoever on the statements of my paper, since that was written before he had divulged his secret to the world.

That these photographs were shown at the Tenth International Medical Congress in Berlin, a thing to which your correspondent feelingly alludes, I take it, proves nothing more than many other demonstrations in medical matters that have been more conclusive to the authors or demonstrators than to others. Your correspondent goes on to say that the existence of these pure cultures was known to me before my article was published. Now to one who runs and reads this statement might easily be deceptive. As before stated, the first intimation I had of his pure cultures was that which I obtained when in his reply to my criticism he produced his photographs before the society. My paper was handed in to your Journal as it was read before the society, and I take it, it neither behooved me nor was it necessary for me to make any corrections or after-statements. His reply to me was given full justice in the report of the proceedings by the *Medical Record*, and it is my particular desire to call the attention of your readers to a clear statement of this point. It seems to me it became your correspondent to make this plain beyond peradventure.

Your correspondent quotes the following from my article: "The small bacillus (together with the clubbed bacillus) was found in the secretion in every case."

He writes in reply: "There is no authority whatever in my article for the clause included in parenthesis in this quotation."

On page 13 of this reprint from the *Medical Record*, May 21, 1887, he writes: "Having found a medium on which the bacillus would develop, although feebly, my next endeavor was to make a *pure culture*." (Italics your correspondent's.) "The bacillus in the tubes was contaminated with a club-shaped [bacillus?] (or one that soon became clubbed) which developed about as rapidly as the small bacillus, and repeated endeavors to separate the two *proved fruitless*." (Italics my own.) Fur-

ther on he states that he was unable to separate the two, even though they were carried to the sixteenth generation.

Your correspondent refers to his test tubes, but, as these were inoculated originally from cases, the statement by inference holds equally good for them.

I admit freely that the "clause included in parenthesis" does not occur in his original, but its equivalent does, and that man must be narrow, hypercritical, and unreasonable who demands that a thing should always be said in the same language.

It is clear to my mind that there *is* authority for the "clause included in parenthesis," the statement of your correspondent to the contrary notwithstanding.

JOHN HERBERT CLAIBORNE, M. D.

PRELIMINARY CAPSULOTOMY IN THE EXTRACTION OF CATARACT.

SYRACUSE, N. Y.

To the Editor of the New York Medical Journal:

SIR: In your issue of September 20th Dr. T. J. Tyner's interesting communication upon the subject of Preliminary Capsulotomy in the Extraction of Cataract contains the statement that he has been unable to find a precedent for the operation described. The same procedure, however, was described by Drake-Brockman in 1884 and possibly earlier; and by Hiemel, of Leipsic, in 1888. Drake-Brockman gives a complete statistical report of his cataract cases in the *Ophthalmic Review* (August, 1884, and November, 1888). He had, up to the date of his last communication, operated by this method two thousand one hundred and seven times.

The method is described under the name of "primary capsule rupture," a term which seems preferable to that of "preliminary capsulotomy," as the latter suggests an interval of time between capsulotomy and the extraction of the lens (as in preliminary iridectomy).

Hiemel's paper was read before the International Congress of Ophthalmology held at Heidelberg in 1888, and reference to it will be found in the *American Journal of Ophthalmology* for that year.

I was more particularly interested in Dr. Tyner's communication because three years or so ago the same idea occurred to myself, and I thought it original until shortly afterward I read the record of Drake-Brockman's immense experience in cataract operations. If one may judge from the brief notice of Hiemel's paper, it seems possible that he also was under the impression that his procedure was a new one. Of the value of the procedure Drake-Brockman's experience seems to leave no doubt.

F. W. MARLOW, M. D.

Proceedings of Societies.

CANADIAN MEDICAL ASSOCIATION.

Twenty-third Annual Meeting, held at Toronto, September 9, 10, and 11, 1890.

The President's Address.—Dr. I. Ross, the retiring president, in his opening address, gave a *résumé* of the year's progress in medicine. He spoke of the success of the meeting of last year, which was held at Banff Springs, in the Rocky Mountains. The desirability of the establishment of a system of registration of medical degrees, uniform for the whole Dominion, was pointed out. At present, as the law now stood, a practitioner must take out a license to practice for each province. The system of contract work and supplying medical attendance to benefit societies at low rates of remuneration was condemned.

The Address in Medicine was given by Dr. PREVOST, of Ottawa, who chose as his text the advances made in medicine recently by the aid of bacteriological research, alluding to the work of Pasteur and Koch. But first he dealt with the recent increase of our knowledge of nervous diseases and the improvements evident in the treatment of such diseases as hysteria and insanity. This paper was received with great interest, not only from its excellent character, but from the fact that the speaker, a Frenchman by birth and education, chose to use English in his address out of compliment to the nationality of the large majority of his hearers.

The Address in Surgery was intrusted to Dr. CHOWN, of Winnipeg, who, after some general remarks on the progress of surgery, approached the special subject he had chosen, the pathology and treatment of hydatid disease. In the Province of Manitoba there were very many Icelandic immigrants, among whom hydatid disease was very common. The speaker then narrated the history of a case of hydatids affecting the abdominal cavity and several of the organs. The abdomen was opened and the cyst removed. The address was illustrated with the exhibition of numerous preparations of cystic parasites.

The Address in Obstetrics was given by Dr. J. CHALMERS CAMERON, of Montreal, who selected the subject of Temperature in the Puerperal Period. It was necessary, he said, to have clear ideas respecting the normal and physiological before we could understand the abnormal and pathological. After describing fully the course of the temperature and pulse during the latter months of gestation, labor, and the puerperium, he drew the following conclusions: 1. The temperature of a healthy pregnant woman during the last four months is the same as in the healthy non-pregnant state. 2. Labor raises the temperature. The amount of rise depends upon the length and severity of labor, particularly of the second stage. It is higher in primiparæ than in multiparæ, higher after irregular than after regular labors. 3. In the first twenty-four hours after labor the temperature rises and then falls, the height it attains depending chiefly upon the time of day when labor terminates. The rise is greatest in labors terminating during the day, least in labors terminating during the night. 4. From the second to the eighth day the average daily temperature varies less than half a degree from day to day; but there is a diurnal variation of one degree to one degree and a half between the maximum and minimum of each day. The maximum daily temperature is usually at 10 A. M.; the minimum at midnight; the average at 6 A. M. and 8 P. M. The daily observations should be made at these latter hours. 5. The pulse falls steadily from the conclusion of labor to the end of the first week from 61 to 50. The fall is equally marked in primiparæ and in multiparæ. There is a difference of 17 between the maximum and minimum of each day. It is slowest at midnight, quickest at 8 A. M. 6. In hospital practice the best results show a normal temperatnre curve in about seventy per cent. of the cases. In private practice the ratio should be at least eighty per cent.

After showing the fallacy of popular notions respecting so-called milk-fever and ephemeral fever, it was contended that a rational treatment could only be attained when the profession grasped the fundamental fact that the normal temperature curve during the puerperium differed little from that of health, that lactation was a physiological process, unattended with fever, and that when febrile symptoms did occur, their explanation must be sought in some pathological condition, not in the establishment of a physiological function.

In describing the ætiology of fever during the puerperium

the cases were divided into infectious and non-infectious. It was argued that septic conditions were far more common than was usually supposed, for septic wound infection might vary in the severity of its course and symptoms, like scarlatina, smallpox, or diphtheria. The *modus operandi* of septic wound infection was minutely described, and a short description given of the origin, symptoms, and course of vulvar, vaginal, and uterine inflammation. cellulitis, lymphangeitis, peritonitis, and acute septicæmia, illustrated by charts. The course of lung troubles, the exanthemata, erysipelas, diphtheria, etc., in the puerperal period was described and some differences of opinion were explained and reconciled.

Among the non-infectious febrile conditions, emotional fever, exposure to cold, and reflex irritation, such as from digestive disturbances, were fully considered and illustrated by charts and cases.

Since a high temperature during the puerperal period might mean a great deal or nothing, the necessity of a careful diagnosis was insisted upon before severe intra-uterine medication was adopted. Without diagnosis treatment was apt to be one of passive expectancy or else fussy meddlesomeness. In conclusion, a strong appeal was made for rigid antisepsis during the progress of labor, the accoucheur taking as much precaution with himself, his instruments, and the genital tract as if about to undertake a surgical operation. The use of lubricants, frequent or prolonged vaginal examination, and routine douching during the puerperium were deprecated. The use of corrosive sublimate (1 to 1,000) for the hands and external washings, 1 to 2,000 for vaginal douche after labor, the careful inspection of the vulvar and lower fourth of the vagina after labor, and the closing of tears and fissures, were strongly recommended. The routine use of the thermometer often gave the first warning of inflammatory mischief and enabled precautionary measures to be taken. Gynæcologists told a sad tale of the miseries and sufferings of women from neglected inflammatory troubles traceable to confinement, which could readily have been prevented. Such a record was not creditable. We should not merely be content that our patients recovered; we should be concerned as to how they recovered, and timely care and attention would insure comparative immunity from a host of distressing ailments which rendered the lives of women a burden; so it was our bounden duty as humane men and intelligent physicians to realize our responsibilities and adopt all reasonable precautions.

The Medical Section.—After the reading of the surgical address the sectional work began. The chair was taken by Dr. McPhedran, of Toronto, Dr. F. G. Finley having been appointed secretary.

Cardiac Complications of Gonorrhœal Rheumatism.—Dr. R. L. MacDonnell, of Montreal, read a paper in which he reviewed the literature of the subject and analyzed the histories of twenty-seven cases of gonorrhœal rheumatism treated in the wards of the Montreal General Hospital. Of these, there were six in which the physical signs of cardiac disease were found, but in three it was possible that an endocarditis from acute rheumatism or from scarlet fever might have been present. In the remaining three cases no other cause but gonorrhœal rheumatism was present. In the last case recorded the patient, aged twenty-two, while suffering from a urethral discharge, was exposed to cold, and had rigors and slight pains in the joints, principally in the knees. These symptoms were followed by præcordial pain and urgent dyspnœa. Physical signs of pericarditis were almost immediately discovered. Subsequently pleurisy developed and a murmur supposed to be of endocardial origin remained. The reader of the paper concluded from these observations that gonorrhœal rheumatism was sometimes, though very rarely, associated with affections of the endo-pericardium and the pleura.

Dr. J. E. Graham, of Toronto, was not prepared to agree with the reader of the paper as to the exact diagnosis of the last case cited. He thought it not improbable that the cardiac and pleural attacks were due to ordinary acute rheumatism, and that the pressure of the urethral discharge had no bearing upon the case. In support of this view he brought forward the fact that the joint pains were of a very trivial character and that it was not uncommon in cases of ordinary acute rheumatism to meet with severe cardiac symptoms where articular manifestations were almost altogether in abeyance. Another explanation of the occurrence of cardiac valvular affections with gonorrhœa might be found in the possibility that a recent gonorrhœa might light up an old endocarditis, just as in malignant endocarditis the seat of old-standing disease on the valves was found to be the special point of attack.

Dr. MacDonnell said in reply that in some of the cases of supposed gonorrhœal endo-pericarditis the joint pain was entirely absent, and that, in the opinion of some of the writers he had quoted, notably Marty, joint affection was not considered a necessary middle term between the urethral discharge and the heart affection.

(*To be concluded.*)

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Twelfth Annual Congress, held at Baltimore, on Thursday, Friday, and Saturday, May 29, 30, and 31, 1890.

The President, Dr. John N. Mackenzie, of Baltimore, in the Chair.

(*Continued from page 274.*)

Look beyond the Nose.—Dr. S. Solis-Cohen read a paper with this title. (See page 340.)

Dr. Roe: The communication which has just been read touches a subject upon which I have myself written a paper; and I have but little more to say on the topic discussed. One point, however, I may refer to: It is the nervous symptoms of nasal obstruction. Headache, of course, always indicates something wrong, some abnormal condition; but any man who attempts to ascribe a headache in every instance to a single specific cause should be regarded as scarcely less abnormal than the headache itself. There are unquestionably a great many headaches produced by diseases of the nose, but this is very far from saying that all headaches are thus caused. We see two cases of headache attended by precisely the same condition in the nose—for example, pressure of a turbinated body upon the septum. In one case the removal of the obstruction will relieve the headache at once, in the other the same treatment will have no effect upon the headache. The explanation of this is that in the latter case the headache is due to some other cause. Where the headache is relieved by an operation it is probably because there was some pressure upon nerve-filaments, the irritation being transmitted to the brain by nerve connection; the operation cures by removing the source of irritation. The result, however, can not always be predicted. We can not always promise that the headache will at once disappear, but the operation is proper under the circumstances. I have seen many cases in which complete relief from a persistent headache followed the removal of a nasal obstruction. About two weeks ago a man with nasal difficulty came to me for treatment. He said nothing about headache, and I did not ask him regarding such a symptom.

Having been relieved of the abnormal condition in the nose—there was marked pressure between the middle turbinated

body and the septum—he returned to me very grateful and said that I had cured his headache also. It seemed that for three or four years he had suffered from headache, and he had been told by a physician, who had unsuccessfully treated him for it, that it was constitutional, and he had made up his mind to bear it for the rest of his life. Thinking it incurable, he said nothing to me about it, and was much surprised to find after the operation that it had disappeared. Of course, the facts in Dr. Cohen's paper go without saying. It is well known that we may have a variety of symptoms from the same cause, and a local condition does not always give rise to the same nervous disturbance. The nasal obstruction may be the primary cause of a headache, or it may be only an incidental concomitant.

Dr. JARVIS: The last speaker has recalled to my mind a thought which may throw some light upon the fact that nervous symptoms appear in one person and not in another. I have seen a large number of such cases in dispensary and private practice and have often noticed this phenomenon. Among the poorer classes we find marked distortion of the nasal septum, and nasal obstruction is very common, but it is apparently not attended by much discomfort, since the nervous symptoms which are usual among the wealthy class are entirely wanting. In reading Stanley's account of his African expedition, I was much interested in his statement that the native Africans paid but little attention to their wounds; and even when severely lacerated and torn, they acted as if they were mere scratches; the wounds, furthermore, healed quickly, in marked contrast to those of the whites of the party, who suffered seriously from the slightest injuries. The blacks for generations had been used to exposure of their bodies, and in consequence their nervous system had become accustomed to injuries of this kind—in other words, they had become less sensitive to external irritation. There is just this difference between the educated or wealthy and the laboring classes: the latter are far less susceptible to external irritations than the former, on account of the inertia of their nervous system. I have found a slight amount of nasal obstruction in a brain-worker producing a great deal of distress, headache, etc., while a much greater amount in a laboring man may give rise to no discomfort at all. The nerve symptoms are due to the increased susceptibility of the central nervous system to peripheral impressions.

A Case of Myxoma of the Naso-pharynx in a Child Six Years Old.—Dr. ALEXANDER W. MACOY read a paper on this subject. (See page 341.)

The PRESIDENT said that he had reported two cases of myxoma and had referred to them in Dr. Keating's *Cyclopædia of Diseases of Children*. "They occurred in the same family, in brother and sister; one was four years of age and the other six. In the one, the mother had noticed something protruding from the nose at one year of age, in the other the growth was probably congenital in origin. I removed both with the cold wire snare. These growths in children are not common. Morell Mackenzie in all his large practice never saw one under the age of sixteen years. Bartholini and other older writers reported cases of polypus in children, but in those days the diagnosis was not made as carefully as at present, and the distinction was not clearly drawn between these cases and simple hypertrophy."

Dr. SWAIN: This tumor has the appearance of a fibro-myxoma. I have seen such a case in a child eight years of age. I do not know the outcome of it, but think it may be of interest to mention it in this connection.

A Case of Fibro-sarcoma of the Right Nasal Fossa with Unusual Clinical History.—Dr. C. H. KNIGHT read a paper with this title. (See page 342.)

Dr. BOSWORTH: The author takes the ground in this paper that the more radical operation is indicated in sarcoma of the naso-pharynx. In this I take issue with him, and regard the question as far from being settled. The only case of sarcoma of the naso-pharynx followed by recovery that I know of was one in which a severe operation could not be borne and the patient was treated with the mildest measures only. I reported this case to the American Medical Association several years ago. Butlin, in his monograph, says that sarcoma at first is a purely local disease. I hold that if we treat it as a local disease we are on safe ground. At the present time we can get at all parts of the nose without resorting to the operations mentioned; the old operations are no longer necessary. The best results have followed the plan of attacking the growth through the nose and, by careful manipulation, taking it away piecemeal. In my own experience, sarcoma is best treated in this way, using the cold wire snare. In carcinoma it does not matter what is done; my experience is that no form of treatment is of service.

Dr. MULHALL: I wish to place upon record a case bearing some resemblance to the one which Dr. Knight has just reported. It was one of small-celled sarcoma invading both nostrils. The case also has some bearing upon the question of the traumatic origin of these growths. The patient, a man about fifty years of age, had been injured by a fall upon the railroad, striking his nose upon a tie, about a year before the disease appeared, and he attributed the disease to the fall. He came to me with a mass of bleeding, fungous material projecting from both nostrils. Upon touching it, hæmorrhage was caused. I questioned if any operation would be of service, but I advised the removal piecemeal with the galvano-cautery and discountenanced any radical operation. After I succeeded in clearing one nostril, he gave up coming to me, and resorted to the use of morphine. He died in about four months with repeated hæmorrhages and inanition; the disease lasted about a year altogether.

Dr. BOSWORTH: The case is reported as one of fibro-sarcoma. Was there any change in the character of the tumor or its appearance corresponding with the occurrence of malignancy?

Dr. KNIGHT: While under my observation the neoplasm was fibro-sarcomatous. In speaking of the "radical operation," I refer not to Chassaignac's or Ollier's, but rather to one like Maisonneuve's, which exposes the region to its utmost limit. It may be true that carcinoma is better let alone. Is it not equally true in sarcoma that a policy of non-interference is more judicious than a prolonged series of nibblings at the surface of a growth which is steadily progressing beyond our reach?

Adenoid Tissue in the Naso-pharynx and Pharynx; Preliminary Report.—Dr. H. L. SWAIN, of New Haven, read a paper on this subject. (See page 316.)

Dr. BOSWORTH: Dr. Swain's paper is very interesting and timely. Just now considerable attention is directed to the lymphatic tissue in the vault of the pharynx, the base of the tongue, and in the fauces. What are its functions? what its pathological relations? but, prominently, what constitutes a pathological condition of this structure? I confess that I do not look with much favor upon the speculations which have been advanced as to the function of this tissue. For instance, when Scanes Spicer says that it is placed there to drink up superfluous fluid, it does not, in my opinion, rise to the dignity of a physiological theory; nor, when Killian says it is there in order to destroy micro-organisms, do I regard it as much more rational. It is very evident that it can act upon only a very small part of the inspired air, and can exercise only a very slight effect in this way. In diseased conditions it might, on the contrary, act as traps for pathogenic micro-organisms, and afford a suitable culture ground, as in diphtheria. As a matter of fact, many of the diseases of young children are contracted in this way, such as scarlet fever, measles, diphtheria, follicular

amygdalitis, etc. All of these are evidently due in many cases to the fact that these disease germs are introduced and developed there. Again, in confirmation of Killian's theory, may it not be that this function of destroying organisms is itself destroyed by the diseased condition of the glands which arrests their function? Another important question to be solved is, What constitutes a diseased condition of the adenoid tissue in the vault of the pharynx? Are adenoid growths abnormal? Are the small pearly bodies so often seen there evidence of disease? Again, the manifestations of a catarrhal process in this region are different at different ages; up to fifteen or twenty years of age this region is the most frequent source of a catarrhal discharge; from twenty to forty, intranasal disease is the rule; while from forty to sixty it is back again in the naso-pharynx. In children the disorder is due to hypertrophy of the lymphatic structures in the vault of the pharynx; in adult life the adenoid tissue is shrunken up, and atrophic changes occur. Another problem is, Where does all the mucous secretion come from in cases of naso-pharyngeal catarrh? Adenoid tissue does not secrete mucus. What is the possible source of the discharge? It is possible that the pain may be due to the shrinkage of the adenoid tissue which imprisons the terminal fibers of nerves; but where does all the secretion come from? I do not believe Schwalbach's theory; it is not reasonable, and I can not accept it. At the opening of a recent meeting of the British Laryngological Association, Mackenzie Kennedy said that if any one could tell us how to cure naso-pharyngeal catarrh he would confer the greatest benefit upon laryngology. We treat it, it is true, after a fashion, but, after all, do we know anything about it?

Dr. Langmaid: I would ask Dr. Swain to illustrate his remarks upon the blackboard. What is meant by the statement that when there is a demand by the blood for more leucocytes there is a diminution of adenoid tissue?

Dr. Bosworth: I should like to ask, also, if the author based the remark that adenoid-tissue function was to make blood upon any personal observation or experiment?

Dr. Swain: In answer to Dr. Langmaid, the only observations I know of are those made by Stöhr and two made by myself. Stöhr found that in a case of pyo-pneumothorax, upon examination of the throat, there were hardly any follicles in the adenoid tissue; and, secondly, that the number of leucocytes lying in the epithelium was very much less. In a case of leucocythæmia he made similar observations, although the appearances were not so well marked. My own observations were in a case of bone tuberculosis, and in one of pure pulmonary tuberculosis. I found in the lingual tonsil there was great diminution and atrophy of gland tissue at the base of the tongue. The conglobate glands were very much atrophied.

With regard to the point raised by Dr. Bosworth concerning the source of the great quantity of secretion, in the observations made by Killian and in my own there was no connection found between the amount of increase in the adenoid tissue and that in the racemose glands, increase in the latter not always following the same in the former. As to the explanation referred to by Dr. Bosworth, why it was necessary for the lymphoid tissue to go through this process of diminution and atrophy, I can not say anything, except that it *is* necessary. We see it so much in our cases that we must believe it to be the inevitable course of adenoid tissue in this situation to undergo this degeneration and atrophy. I may not have made it very clear in my paper, but I think the point made by Killian a very important one.

Supplemental Report on Cartilaginous Tumors of the Larynx and Warty Growths in the Nose.—Dr. E. Fletcher Ingals, of Chicago, read a paper on this subject. (See page 345.)

Dr. Bosworth: In connection with this subject I will refer casually to a case I saw four months ago. It was a broad papilloma upon the tongue and palatal arches in a child three months of age. I applied thuja occidentalis, but without any effect whatever. The growth subsequently disappeared under the use of glacial acetic acid. I thought this case might be interesting as showing the failure of thuja. These growths in the nose are quite frequent. I have seen half a dozen cases within the last year; they are probably usually mistaken for small polypi. In my cases I snared them off and cauterized the base with chromic acid. My own experience has failed to show me where the reputation of thuja has been maintained.

Dr. Jarvis: I have had some experience in connection with these growths, especially in their treatment with chromic acid, when occurring in the larynx. I was perhaps the first to point out the fact that this agent would completely remove the growth as well as prevent its recurrence. Hering afterward came out in its favor. There is one point about it that should be mentioned—namely, the advantage that it does not reach beyond the papillomatous tissue in its effects; it furthermore does no harm to the healthy mucous membrane in the immediate vicinity of the growth. This is due to the diversity of the tissue. Cartilage is not affected by small applications of the acid. It acts by progressive superficial sphacelation. The effect is regulated by the quantity used; if small, no danger can follow. I have seen only two cases of nasal papilloma. One I should not call a case of true papilloma. It was in a boy about sixteen and was a modified polypus—a polypoid growth, in fact. It had not the raspberry-like, irregular surface, but it had been altered by previous applications. I called it a teleangeiectatic polypus. It bled easily. The other case I at first considered one of true papilloma, but afterward came to the conclusion that it was a case of epithelioma, as I think many of them are. It was not changed by long treatment, and extreme radical measures had no permanent effect upon it.

Dr. Mulhall: There seems to be some confusion in this discussion between warty growths and papillomata. I recall a paper by Hopmann, who professed to have seen a hundred and twenty cases of warty growths in the nose. I wondered why I had never seen a case. A patient applied to me a short time ago for treatment for "warts" in his nose, which I found to be papilloma, such as we find in the larynx. It grew from the anterior portion of the middle turbinated bone, and looked exactly like a small bunch of grapes. I saw the case just before I left, and operated upon it. It was readily removed, and the operation afforded much relief to the breathing. I desire to place this on record as the first case I have seen of papilloma of the nose. (The speaker presented a specimen of nasal papilloma.)

The President inquired of Dr. Mulhall if the growth in his case was large and if it might not have been a portion of the erectile body.

Dr. Mulhall: The growth was large and could be withdrawn from the nose partially, but again retracted; it was somewhat elastic. The middle and upper turbinated bodies were free.

The President: I have seen prolapse of the mucous membrane from the anterior portion of the turbinated body which could be withdrawn from the nose in the manner just mentioned, and which had been mistaken for polypus.

Dr. MacCoy: I can recall three cases of warty growths, all growing in the vestibule, having the appearance already described. I removed them with the galvano-cautery. There was some tendency to return, but they were all ultimately cured.

Dr. Delavan: One of the interesting features of this discussion is the general consensus of opinion as to the rarity of

the case. I was much surprised at the statements of Hopmann, and think that there must be something peculiar in the cases coming to him, as in my experience papilloma in this situation is a rare disease.

The PRESIDENT: I fully agree with Dr. Bosworth that these papillomatous tumors are likely to grow just within the vestibule, and are more common than is generally supposed; but growing further within the nose they are rare. I can recall only two cases of this kind in my experience. I think the remark of Dr. Jarvis very well founded and appropriate. Where we find a papillary growth with a broad base and a tendency to bleed we should be on the lookout for carcinoma. I think that Hopmann mistook for papilloma the changes that occur in the ordinary transition from the secondary to the tertiary form of chronic rhinitis. Cross-sections of these bodies under the microscope resemble papillomatous tissue, whereas they actually consist of turbinated erectile tissue. I think that Hopmann, in some cases at least, mistook these outgrowths for papillomata. I desire to call attention to an important clinical point: Sometimes patients complain for a long time of a sense of fullness of the nostril and other symptoms of hypertrophic catarrh, and after a while expel little pieces of flesh, as they term them, from the nose. Afterward they find that they can breathe better, and that the obstruction in the nose has disappeared. The reason is, that under the influence of the atrophic process these little bodies are separated and slough off. It does not mean that the patient has gotten well, but simply that the hypertrophic process has gone on to atrophy. Under the microscope, sections of these bodies resemble papillomatous growths in structure, and may be mistaken for them, while they are really the results of hypertrophic degeneration.

Dr. INGALS: I think that this mulberry-like appearance of the turbinated body is probably the reason that Hopmann, and probably some others, have found so many so-called cases of papilloma of the nose, as a mistake might easily be made. I have often seen this condition, which is not that of a true papilloma, but I have never seen but the one reported in which the growths had the appearance of warts. In this particular case the growths, which recurred many times, did not resemble papillomatous tumors in the larynx in any way. They grew first from the septum, and afterward from the turbinated body, and had all the appearance of warty growths as we commonly see them upon the hands.

As to the thuja occidentalis: I did not wish to try to prove that it had any special value, though this has been alleged for it: but I must say that the patient did much better after using it than he had been doing before. It is possible that it may make some difference whether a fresh tincture is used or not. The preparation I employed was prepared at the time from the fresh leaves of the arbor vitæ.

Hoarseness and Loss of Voice caused by Wrong Vocal Methods.—Dr. S. W. LANGMAID, of Boston, read a paper on this subject. (To be published.)

Dr. DELAVAN: It will be generally conceded that no higher authority than Dr. Langmaid could discuss the questions presented in this paper. To it we can only add the testimony of our own experience. From the statements of noted singers who have been trained under the system which the reader of the paper describes, as well as from my own personal experience in practical vocalization, I am able to confirm the views which he has expressed. Not infrequently cases have come to me complaining of some laryngeal difficulty in which a diagnosis from simple inspection of the larynx was impossible, and a correct solution of the matter only arrived at by a careful study of the vocal methods of the patient and the discovery of its defects. In many instances faulty voice-production will be found to be the true explanation of an otherwise inexplicable difficulty. Of course it is of great importance for us to understand our cases in order that we may properly treat them, and, understanding them, to see that the treatment employed be not confined to local applications, but that the faulty methods of vocalization be corrected under the training of a competent teacher. Again, the services of the vocal instructor are of great value in the treatment of certain chronic conditions of laryngeal disease. I am in the habit of referring patients to a skillful teacher for the purpose of obtaining systematic exercise of the laryngeal muscles, just as in appropriate cases the surgeon resorts to passive motion. It is to be hoped that Dr. Langmaid will continue to offer us such studies as this through his work. Aided by that of Dr. French, we should be in a position to recognize and successfully treat many cases which now are wholly misunderstood.

Dr. HINKEL: I am reminded by the paper of a class of cases in which I have taken much interest—cases in which there is vocal disability due to some structural defect in the nasal passages or naso-pharynx. Such patients suffer injury to the throat and voice from the demands made upon the vocal organ beyond what is customary in speech, even though there be nothing faulty in the vocal method. It is of importance to recognize this defective condition, for many teachers and pupils are puzzled to account for the failure of promising voices in which the defect is due to a lack of co-ordination, as it were, between the primary tone-organ and the resonating apparatus. The removal of a septal ridge or of adenoids not infrequently restores the power and quality to the voice. I recall a tenor who gained a minor third in his compass after the removal of a septal ridge from which he had suffered no inflammation or obstruction of which he was aware.

Dr. MULHALL: The matter which the last speaker refers to is hardly germain to the subject of the paper. If we were to go into the discussion of the effects of abnormities of the air-passages upon the formation of tone we should hardly get through with it before our final adjournment. There is one point, however, that I would like to have discussed. It is the so-called "abdominal" method of singing or managing the voice. I wish that every singing-master could have this paper of Dr. Langmaid's put into his hand. I agree with the essayist that any singer who is *conscious of effort above the clavicle* while singing is using a wrong method. I wish to speak of the abdominal method. We notice with what ease the tenor of the Italian opera produces the high notes without even flushing his face, and he can sing the whole evening without apparent fatigue, because he has had the benefit of proper training in the formation of tones and uses his abdominal muscles in singing. I recall the case of a theological student who found in preaching that he got tired in half an hour and lost his voice. I found that he was using his sterno-cleido mastoid and other neck muscles in producing his pathetic effects. I instructed him to concentrate his mind upon the action of his abdominal muscles in public speaking and to forget his throat. He practiced this and taught himself this method that I have described, and found that he could preach for two hours at a time without any hoarseness whatever. The method of using the voice by which the very walls of the theatre are made to vibrate with the volume of sound is familiar to those who attend Italian opera; the effects are produced by the action of the abdominal muscles and the diaphragm. Many singing-teachers in this country apparently do not know this. The teachers in the theological seminaries do not know how to instruct students in the proper use of these muscles. I might mention a case which may not be exactly germain to the subject. A prominent teacher in St. Louis sent one of her pupils to me

because she could not get beyond a certain note in the scale. Upon examination, I found a very peculiar condition. As the voice rises in the scale the epiglottis usually becomes more and more erect, becoming vertical with the high notes. This young lady had enlarged papillæ at the base of the tongue, which were so large as to interfere with the epiglottis and prevent it from erecting itself to form the notes. I removed these growths with a wire snare, and it added two notes to her upper register and gave a really brilliant result.

Dr. Mackenzie: Faulty training must be recognized as a cause of vocal defects, and in overcoming them much time and patience are needed. I agree with Dr. Mulhall in regard to bridling the tongue. The isolation of the naso pharynx is due to the rising of the dorsum of the tongue to meet the descending walls of the pharynx and uvula. The motions of the tongue have a great deal to do with the formation of tones, and anything encroaching upon the naso-pharynx or the tongue is an important factor in the destruction of the mechanism of voice. The instruction given by singing-teachers to keep the tongue upon the floor of the mouth is not physiological. It checks and cripples the movements of the throat muscles, the tensor palati, and the middle constrictor of the pharynx; even the buccinators are under restraint. It is the opinion of Meyer, of Zurich, that the middle constrictor of the pharynx is not concerned in swallowing, but is concerned in speech and in singing, therefore a very important agent in vocalization. In the production of certain notes there is a pushing forward of the middle fibers of this muscle toward the palate. It has been shown conclusively that this bulging of the middle constrictor muscle, upon which the soft palate rests, is of special use, as together they produce a complete isolation of the mouth and nose in the production of certain notes. With regard to Dr. Hinkel's observation, the fact is already well known. With regard to Dr. Mulhall's remarks, it was Mandl who pointed out in his writings with more clearness than the others the importance of the abdominal method. In the Italian school great attention is paid to this method of developing the abdominal muscles. The suggestion of Dr. Mulhall is a very proper one, and should be put in operation in our daily work; by it we may succeed in curing cases that otherwise we could not benefit.

Dr. Langmaid: I feel gratified by the discussion which has been given to the subject, which I have had under consideration for a long time. I have said in my paper that there are wrong vocal methods, and I have been asked to formulate the right vocal method. I know many wrong ones from the effects that are produced by them; what is the right one I hope to be able to state at some future time. With regard to the class of singers referred to, who are conscious of effort and difficulty in the use of their voice, we must be careful in our advice and prognosis. I have been impressed for years that the method of holding the tongue down in the production of vocal sounds is a wrong one. I made many observations during several years, and became finally convinced that this was the source of all the difficulty in certain cases. I found patients relieved by correcting this method, so that I am satisfied that this was a correct view. Dr. Hinkel referred to the fact that nasal stenosis produces changes in the voice, and Dr. Mackenzie seems to agree with him that such disorders are frequent causes of voice difficulties. I am satisfied that Dr. Hinkel is correct in his observation upon his case, but I am not satisfied that it is by any means a great cause of voice defects. A partial filling up of the naso-pharynx is not constant in its effects upon the voice; it may or may not impair it. Of course, if the pharynx were completely filled it would affect the voice, but there is no evidence that a partial filling up would have any such consequences. I entirely indorse the remarks by Dr. Mulhall with regard to the taking of the attention away from the throat; it is very important to a correct vocal method. I also approve his remarks upon the abdominal method. This is very interesting, and I intend to make some observations upon breathing if I live long enough. There is much to be learned with regard to correct methods of breathing. With reference to the case of the clergyman, the observation was a just one. I have elsewhere said that the laryngeal muscles were in position to place the vocal organs in proper place to form a given tone without the wind-blast. The wind-blast does not produce the pitch; the larynx is properly adjusted for the tone before the wind-blast reaches it. If we had to depend upon the delicate adjustment of the wind-blast, how many would be able to sing in tune? The muscles instinctively put the cords in position to produce the note, which is virtually produced before the wind-blast comes, which puts them in vibration and gives out the tone. When the wind-blast is strong it seems as if the cords would not be able to resist it, and yet they do not yield. The station, as I call it, is immovable when the wind-blast comes; the muscle does not give at all; if it did, the tone would change and be either sharp or flat. Therefore the distinction is that the note is not made by the wind-blast, but it is carried on by the wind-blast, and intensified by increase of the wind-blast. Now the question comes up, "What portion of the abdominal muscles should be brought into play to produce the result most effectively?" This I will reserve for future consideration. With regard to the case of Dr. Mulhall, I described one exactly similar to his. I made one attempt to remove the growth and told the patient to come back, but he never did. The growth in this case had already decidedly impaired the mobility of the epiglottis. In reply to Dr. Mulhall, I might state that in a paper by Morell Mackenzie upon the voice he says that some singers protrude the abdomen and some retract it. With regard to the tongue, we must remember that tongues are of different shapes naturally; some are flat and broad, others narrow or wedge-like. Because some singers sing with a flat tongue, it does not follow that others must do it. I am satisfied that the position and shape of the tongue depend upon the motions of the muscles of the larynx. The fact is that some singers sing with the back of the tongue raised, and it is also a fact that others, equally good, sing with the tongue flat.

The President: What do you think of the method in which the tone is thrown to the bridge of the nose?

Dr. Langmaid: This question might be construed the wrong way. That the resonance is universal and involves the hard parts and also the soft parts is true; that the voice which is not reflected is a dull voice, as the singer says, is true; but that these are the only parts which reflect the voice is certainly not true; ill results to the laryngeal muscles and the voice will come from an attempt to follow this method. I have endeavored to confine my paper to one form of wrong method of voice training, so that I could not be contradicted without having an answer prepared. By keeping on one subject I hoped to avoid vagueness in the discussion which would follow.

The President: Do you not think that the nasal and accessory chambers are too much neglected in the usual teaching of singing?

Dr. Langmaid: Not by the best teachers. The methods pursued are those intended to develop the best acoustic qualities. For the same reason the Italians have always made use of the resonance of the head. If you choose to call it nasal resonance you may do so.

Unilateral Paralysis of the Lateral Crico-arytænoid Muscle.—Dr. Ingals read a paper with this title. (See page 346.)

Dr. Bosworth: There is one interesting point which occurs

to me. In several cases of paralysis of one side of the larynx, with complete loss of voice, and in two instances of falsetto voice, the voice afterward became almost absolutely normal; the voice returned, although the paralysis persisted. This was accomplished by the healthy cord swinging over to the paralyzed side so as to make up for the loss of power on that side.

A Case of Unilateral Paralysis of the Abductors of the Larynx, the Result of an Attack of Bulbar Disease with Unusual Symptoms.—Dr. F. H. Bosworth, of New York, read a paper with this title. (To be published.)

Dr. Westbrook: I should like to ask the author of the paper if he would not consider it possible that the short duration of the motor paralysis, the suddenness of onset, and subsequent history of the case, might rather tend to exclude the idea of lesion of the medulla. A lesion of the medulla sufficient to cause so extensive a paralysis, to give complete hemiplegia, I should not think could be recovered from so readily. I should think that a case like this might be accounted for on the supposition of an embolus passing into the middle cerebral artery, or a thrombus in the sinus or in one of the other vessels at the base. An embolus or thrombus affecting the internal capsule might account for the paralysis. But the whole thing might be due to a tumor or clot in one of the venous sinuses at the base of the brain. It seems more probable that it was of this character than that it was a lesion of the medulla itself; a lesion of such extensive nature as this must have been, occurring near the medullary center for respiration and the vaso-motor center, would have been likely to be quickly fatal. At all events, the patient would not be likely to recover so completely or quickly.

Dr. Bosworth: In reply to the question, I would say that there is no doubt about the bulbar nature of the lesion in view of the extent of the paralysis. There was loss of deglutition and of power in other muscles supplied by the eighth pair of nerves; the laryngeal paralysis with hemiplegia all point to the bulb or the origin of the eighth pair of nerves in the floor of the ventricle. The extent of the case, the history of a chronic suppurative process in a closed cavity, suggest thrombosis of one of the small arteries, from the basilar supplying the medulla. The absorption of the embolus would account for the rapid recovery, for the occurrence of softening would naturally take some time. An interesting point is the occurrence of hemiplegia. I recall no case on record in which thrombosis in the medulla caused hemiplegia, which makes this case especially interesting. There was also some cervical adenitis, which still further supported the view of lesion at the base and in the cerebellum.

Book Notices.

International Atlas of Rare Skin Diseases. Editors: Malcolm Morris, London; P. G. Unna, Hamburg; L. A. Duhring, Philadelphia; H. Leloir, Lille. I and II. Philadelphia: J. B. Lippincott Company, 1889.

The issue of this work, to which we have before alluded, indicates the cosmopolitan tendency of medical literature. The description which accompanies each of the plates is given in English, French, and German, first in the language of the author, which is then translated, so that a knowledge of the European languages is not necessary for the complete enjoyment of the work. Parts I and II contain excellent presentations and descriptions of lymphangeioma circumscriptum, ulerythema acneiforme, lupus semisclerosus linguæ, sarcoma pigmentosum diffusum multiplex, keratodermia symmetrica erythematosa, angeiokeratoma, and ulcus molle mammæ. It would be difficult to find better and more life-like presentations of these diseases, and the work should certainly be in the possession of every dermatologist.

Diseases of the Rectum and Anus, their Pathology, Diagnosis, and Treatment. By Charles B. Kelsey, A. B., M. D., Professor of Diseases of the Rectum at the New York Post-graduate Medical School and Hospital, etc. Third Edition, rewritten and enlarged. With Two Chromo-lithographs and One Hundred and Sixty-eight Illustrations. New York: William Wood & Co., 1890. Pp. x–483.

The third edition of this well-known work comes to us revised and considerably augmented. We note in the chapter on hæmorrhoids that the author still views Whitehead's operation with a disfavor that is not entertained by many excellent surgeons. The chapters on the treatment of benign and malignant strictures of the rectum, and on the formation and closure of artificial anus, have been completely rewritten. While the author believes that in certain cases lumbar colotomy is particularly applicable, yet his preference is for inguinal colotomy; and he wisely urges that this operation should not be a *dernier ressort*, but a measure that should be used early to delay the course of malignant disease and often to cure non-malignant troubles. The sections on enterorrhaphy and the closure of artificial anus explain the latest operations for these conditions.

The volume is excellently illustrated, and is virtually a new work.

BOOKS AND PAMPHLETS RECEIVED.

A Text-book of Practical Therapeutics, with Especial Reference to the Application of Remedial Measures to Disease and their Employment upon a Rational Basis. By Hobart Amory Hare, M. D. (Univ. of Pa.), B. Sc., Clinical Professor of the Diseases of Children and Demonstrator of Therapeutics in the University of Pennsylvania, etc. Philadelphia: Lea Brothers & Co., 1890. Pp. vi–17 to 632. [Price, $3.75.]

Salol in Acute Tonsillitis and Pharyngitis. By Jonathan Wright, M. D., of Brooklyn, N. Y. [Reprinted from the *American Journal of the Medical Sciences.*]

A Classification of Intra-nasal and Naso-pharyngeal Diseases. By Lennox Browne, F. R. C. S. Ed., etc. [Reprinted from the *Journal of Laryngology and Rhinology.*]

An Analysis of Some of the Ocular Symptoms observed in So-called General Paresis. By Charles A. Oliver, M. D., Philadelphia. [Reprinted from the *Transactions of the American Ophthalmological Society.*]

An Explanation of the Phenomena of Immunity and Contagion, based upon the Action of Physical and Biological Laws. By J. W. McLaughlin, M. D., Austin, Texas. [Reprinted from the *Transactions of the Texas State Medical Association.*]

Spinal Surgery. A Report of Eight Cases. By Robert Abbe, M. D. [Reprinted from the *Medical Record.*]

Address in Hygiene. By Thomas J. Mays, M. D., of Philadelphia. [Reprinted from the *Transactions of the Medical Society of the State of Pennsylvania.*]

The Relation of Eye-Strain to General Medicine. By George M. Gould, M. D., Philadelphia. [Reprinted from the *Medical News.*]

Transactions of the Association of American Physicians, Fifth Session, held at Washington, D. C., May 13, 14, and 15, 1890. Volume V.

Nouvelle iconographie de le Salpêtrière, clinique des maladies du système nerveux. Publiée sous la direction du Professeur Charcot (de l'Institut), par Paul Richer, Gilles de la Tourette, Albert Londe et Georges Guinon. Troisième année. Juillet et août, No. 4. Paris: Lecrosnier et Babé, 1890.

Medical Diagnosis, with Special Reference to Practical Medicine. A Guide to the Knowledge and Discrimination of Diseases. By J. M. Da Costa, M. D., LL. D., Professor of Practice of Medicine and of Clin-

ical Medicine at the Jefferson Medical College, Philadelphia. Illustrated with Engravings on Wood. Seventh Edition, revised, Philadelphia: J. B. Lippincott Company, 1890. Pp. 16–17 to 995. Price, $6.]

Dust and its Dangers. By T. Mitchell Prudden, M. D., etc. New York: G. P. Putnam's Sons, 1890. Pp. 111.

A System of Oral Surgery; being a Treatise on the Diseases and Surgery of the Mouth, Jaws, Face, Teeth, and Associate Parts. By James E. Garretson, A. M., M. D., D. D. S., President of the Medico-chirurgical Hospital and Emeritus Professor of Oral and General Clinical Surgery in the Medico-chirurgical College, Philadelphia, etc. Illustrated with Numerous Wood-cuts and Steel Plates. Fifth Edition, thoroughly revised, with Additions. Philadelphia: J. B. Lippincott Company, 1890. Pp. xliv–25 to 1364. [Price, $9.]

Massage. A Primer for Nurses. By Sarah E. Post, M. D. Lectures before the Training Schools for Nurses connected with Bellevue, Mt. Sinai, and St. Luke's Hospitals, New York; also with the Memorial Hospital, Orange, N. J. New York: The Nightingale Publishing Co., 1890. Pp. 9 to 47.

Brain Surgery, with Report of Eleven Cases. By H. O. Walker, M. D., Detroit, Mich. [Reprinted from the *Medical and Surgical Reporter.*]

A Few Words on Vaccination. By Major Greenwood, M. R. C. S., L. R. C. P. Lond. Second Edition. London: Douglas & Co. [Price, 6*d.*]

Description of a Series of Tests for the Detection and Determination of Subnormal Color-Perception (Color-Blindness), designed for Use in Railway Service. By Charles A. Oliver, M. D., of Philadelphia. [Reprinted from the *Transactions of the American Ophthalmological Society.*]

Some Points in the Treatment of Gonorrhœa. By Gardner W. Allen, M. D. [Reprinted from the *Boston Medical and Surgical Journal.*]

A Preliminary Study of the Ptomaines from the Culture-Liquids of the Hog-Cholera Germ. By E. A. v. Schweinitz, Ph. D. [Reprinted from the *Medical News.*]

Report of the First Annual Commencement of the Training School for Nurses of Wilkesbarre City Hospital, June 18, 1890.

Zur operativen Entfernung eingeklemmter Gelenkmäuse des Kniegelenkes. Von Prof. Dr. Max Schüller in Berlin. [Sonderabdruck aus der *Deutschen medicinischen Wochenschrift.*]

Neue Beiträge zur Kenntniss der syphilitischen Gelenkentzündungen. Von Dr. Friedr. Rubinstein (Berlin). [Separat-Abdruck aus No. 16 des *Aerztl. Praktikers.*]

Zur Behandlung der gonorrhoischen Gelenk- und Schleimbeutelentzündungen. Von Dr. Fr. Rubinstein in Berlin. [Sonderabdruck aus *Therapeutische Monatshefte.*]

Miscellany.

The American Orthopædic Association.—At the recent meeting, the president, Dr. De Forest Willard, of Philadelphia, after welcoming the members, narrated his experiences in the observation of orthopædics in Europe during the past summer. He congratulated American orthopædic surgeons upon their decided superiority as regarded the application of general and surgical knowledge and the benefit to be derived from operative measures in the correction and relief of deformities. The safety, rapidity, and ease with which many bodily defects could be rectified by the knife and chisel, and the great advances made in the practice of antiseptic surgery, were, as a means of relief, more fully appreciated by Americans than by others. He would, however, give all credit to Macewen for his advocacy of osteotomy, while to Lister belonged the honor of securing that advance in surgery which in its varying applications had revolutionized surgical practice. In regard to mechanical advances, the invention and application of mechanical measures for the correction of deformities, for securing rest, for traction, for immobilization, and for the proper treatment of joint diseases, Americans could justly maintain that they were in the first rank. He then alluded to the orthopædic section of the International Medical Congress, which had been established through American efforts. The most novel idea associated with this particular branch of the work shown at the exhibition of Berlin was the ivory joints of Gluck by which he proposed to replace the excised portions of bone. These joints were intended to remain permanently in position, and to maintain the proper functions of the limb. While the subject was only yet in its experimental stage, in both theory and practice, yet he deemed it worthy of consideration. Dr. Bely's apparatus for the correctiou of deformities of the chest arising from lateral curvature of the spine by weight pressure exercised upon the individual in a stooping posture was highly commended. The president closed his remarks by referring regretfully to the death of two of the members, Dr. Lewis Hall Sayre, of New York, and Dr. David Prince, of Illinois.

ANSWERS TO CORRESPONDENTS.

No. 332.—We think not.

No. 333.—The name is French, not German.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Lectures and Addresses.

THE DOCTORATE ADDRESS

DELIVERED BEFORE THE
GRADUATING CLASS OF THE KENTUCKY SCHOOL OF MEDICINE,
June 19, 1890.

BY THE HON. J. PROCTOR KNOTT,
GOVERNOR OF KENTUCKY.

[AFTER a humorous exordium which at once put him completely *en rapport* with his audience, Governor Knott said:]

Pardon me, however, if I call your attention at the very threshold to the duties and responsibilities of the profession to which you have consecrated your talents, your energies, and your lives. No other calling known among men demands a more absolute self-abnegation than the one you have chosen. No other vocation—not even the sacred ministration of religion itself—requires a more constant exercise of the higher faculties of the human mind or a more earnest devotion of the purer and nobler attributes of the human soul.

The physician who is thoroughly imbued with the true spirit of the Hippocratic oath not only dedicates his life to the service of his fellow-man, but abjures everything that can impair his usefulness, degrade his profession, or debase the dignity of his manhood. Wherever the plaintive voice of human suffering calls—whether from the palace or the hovel, the sumptuous abode of luxurious ease or the infectious wards of the loathsome lazar-house—regardless of every consideration of his own security or comfort, unmindful of the tempest that may rage around him or of the insidious virus of contagion that may steal into the citadel of his life with the very air he breathes, he must go. While the life or death of his stricken patient may hang upon his tenderness and skill he is the anxious sufferer's loadstar of hope, the repository of his confidence, the custodian of his honor, his friend and adviser in his last dark hour, and the comforter of the loved ones who may gather in impotent anguish about his dying couch.

If there is one of your number who has failed to realize in all their awful solemnity the tremendous obligations inseparable from such duties and responsibilities, or who has not resolved that, so far as God hath given him the capacity, he will emulate the virtues and rival the skill of the most accomplished of his compeers or the proudest of his predecessors, I would tell him now, in all sincerity and candor, that he has made a grave mistake in his calling—the noble profession of medicine is not for him.

I congratulate myself in the belief, however, that none of you are so ignoble in your aspirations as to be content with the mean promise of the old Spanish proverb "that in a village where every one else is blind the one-eyed man is king." On the contrary, I feel confident that I voice the unanimous sentiment of your class when I say that one who would be degraded enough to take advantage of the unsuspecting credulity of his fellow-man and ignorantly tamper with his life or his health, with no higher motive than the gratification of a sordid, unholy lust for gain, trusting to the kind offices of the undertaker to hide the evidences of his murderous charlatanry out of sight, it would be the basest flattery to call a scoundrel. I am satisfied that there is not one of you who is not inspired by the noble ambition to become, not only the peer of the proudest of your chosen profession, but *princeps inter pares*.

You should remember, however, that such a position among the truly great does not "come by nature," as honest Dogberry supposed to be the case with reading and writing. If you would occupy it, you must win it for yourselves. If you would wear the laurel, you must bear the heat and dust of the arena. You can never scale the perilous pinnacle of professional distinction by standing idly at its base and gazing listlessly at the coveted diadem that glitters upon its summit. You must climb the dizzy height with slow and painful toil, and you had better realize that fact at once.

Let me conjure you, therefore, to set about it now. Eschew, this hour and for life, whatever may tend to impair your faculties or impede your progress. Concentrate all the energies of your nature upon the achievement of that one grand object and enter upon it with an invincible confidence in yourselves. Do not mistake me, I pray you. I do not mean the ridiculous self-conceit of the contemptible coxcomb of the profession, who imagines, because he has his diploma, that his number six hat covers all the medical science that has been developed since the birth of Chiron the Centaur. When I counsel confidence in yourselves, I mean courage—a brave, manly, unconquerable reliance upon your own exertions; an abiding consciousness that whatever man *has* done man may do again; the cheerful conviction that Hercules helps those who help themselves. You may do this and still incur no risk of being dazzled by your admiration of your own intellectual endowments. Extraordinary as the natural abilities of some of the more brilliant of your profession may appear to you, the mental disparity between them and yourselves is by no means so great as you may possibly suppose. Axtell or Sunol may be able to go a mile or ten miles, perhaps, much quicker than a common plug, but the plug will make it in his own time if he keeps on plugging.

Remember that he who is capable of thoroughly mastering the five fundamental rules of arithmetic may in time, by patient and persistent effort, solve with facility and pleasure the most abstruse proposition in the highest range of mathematics and make himself as familiar with the sublime machinery of the sidereal universe as with the simplest piece of mechanism fabricated by human hands. What he may lack in natural aptitude he may supply by well-directed energy and patient perseverance. Fix your eye steadily upon the bright goal of your ambition and constantly press toward it

> "Like the Pontic Sea,
> Whose icy current and compulsive course
> Ne'er feels *retiring* ebb, but keeps due on
> To the Propontic and the Hellespont."

I am aware that when you look over the long catalogue of illustrious names that adorn the annals of your profession and consider the wonderful contributions they have made to the sciences of medicine and surgery, you are apt to think that your predecessors have left you nothing to do but to practice what they have taught, or, at best, to glean a well-reaped field where there is no glory to be won and no garlands to be woven. Yet there was never a graver mistake. Your profession, with all its marvelous development in learning and all its astonishing exhibitions of skill, has but barely approached the domain of scientific truth and anchored in some of its smaller inlets. The occasional adventurer who has gone ashore has only picked up a few trifling pebbles that lay scattered along the beach. The territory remaining to be explored is as illimitable as the universe itself.

The saying is trite indeed that, of all the great departments of human knowledge, medicine is that in which the accomplished results are most obviously tentative and imperfect—the one in which the range of unrealized possibilities is most varied and extensive, and the one from which the most astonishing and beneficent returns might be expected if the same patient and intelligent investigation were directed to it that has been employed during the current century in mechanical invention and material development. Let me exhort you, then, to learn, above all things, "to labor and to wait." The world was not finished in a day; the mountain-range, whose snow-clad summit is kissed by the earliest gleam of the morning sun, was not the growth of an hour, but the slow product of myriads of ages. The history of human progress is crowded with illustrations of the fact that we are constantly in contact with principles and conditions which have remained unobserved since creation's dawn, waiting for some patient, inquisitive thinker to recognize and develop them—great germinal truths which may become the prolific sources of incalculable benefits to our race; and, for aught we know, the one who will be crowned by the common acclaim of coming ages as the greatest of all the discoverers in medical science the world has ever known, from the age of the Asclepiadæ to the present hour, may be sitting at this moment in your midst.

Have you ever traced the tremendous consequences which have frequently resulted from an accidental thought or the most trivial and aimless experiment? Over twenty-five hundred years ago Thales, of Miletus, observed that by rubbing a bit of amber it was made to attract light objects with which it was brought in contact. Thousands gazed in stupid wonder upon the mysterious phenomenon. It was noticed three hundred years afterward by Theophrastus, and four hundred years later by Pliny; yet none of them ever dreamed that, in the subtle agency which they supposed barely capable of lifting a feather, there lurked the strength of a sleeping giant, more marvelous in the magnitude and versatility of its powers than all the fabled genii of the East. But a little less than a century ago, by the most trifling of all possible accidents, the attention of one of your own profession was directed to the same occult force under different and totally unsuspected conditions. His observations upon the accidental discovery he had made inaugurated a series of intelligent experiments, and to-day electricity is the ready servant of man in all his manifold necessities. Tractable as the homing dove, it carries his messages around the world with the speed of thought. It is the unerring instrument of the enlightened scientist in his most subtle investigations, the indispensable implement of the ingenious artisan in his most delicate handicraft, and one of the most effective agencies of the skillful physician in relieving the sufferings of his fellow-beings. It propels our machinery with the power of a thousand horses, and mocks the effulgence of the noonday sun with the dazzling splendor of its light. And yet how little we know of the real nature or the ultimate possibilities of that wonderful agency which would, perhaps, have remained dormant for ages yet to come but for the initial observations of Galvani!

If I have dwelt at undue length upon this familiar illustration, selected at random from a multitude that might be adduced, I have done so to impress upon your minds, not only the pregnant truth that the wide field of useful labor you have selected teems with rich rewards for your intelligent toil, but the paramount importance of constantly cultivating correct habits of observation and thought. Aristotle was right when he said that "incredulity is the source of all wisdom." You should think for yourselves—closely, carefully, patiently, and independently upon everything that may come under your notice, that may be at all cognate to your profession, and never be satisfied that you know enough about anything as long as anything about it remains unknown. Take nothing for granted that may seem inconsistent with correct reason or established facts, simply because some one of acknowledged authority may have said it; and reject nothing as unworthy of your investigation on account of its apparent insignificance, or because it does not seem to square precisely with the preconceived theories of the faculty.

Had Jenner been less observant, or less inquisitive, or too bigoted, or too indolent for investigation, he would probably have been content to prescribe some simple salve for the pustule on the milkmaid's hand, and thousands would be dying to-day of small-pox who enjoy an absolute immunity from that dangerous and disgusting disease. Whether the old Jesuit fathers taught the doctrine that "the proof of the pudding is in chewing the bag" I do not know; but if the doctor who accompanied one of their early missions to Peru had not adopted the custom prevalent among the aborigines of chewing the bark in order to ascertain the nature of the tree, it is probable that quinine, the *sine qua non* of his more modern professional brethren, would have been postponed for centuries.

In the first year of the present century Sir Humphry Davy suggested the employment of nitrous oxide as an anæsthetic in surgery; but, as the suggestion came from a layman, it was passed unheeded, if not with silent disdain by the great lights of your profession. Eighteen years later Michael Faraday called attention to the anæsthetic effects of sulphuric ether, but it was regarded merely as a matter for curious experiment in the lecture-room, but of no practical consequence. Nearly forty years ago an obscure b

inquisitive countryman happened to be present when one of his neighbors was bitten by a rattlesnake. He not only observed the almost instantaneous effect of the poison, but examined the fang, and finding it to be a finely-pointed tube through which the virus had been injected into the circulation of the victim, it occurred to him at once that the effects of an anodyne administered in a similar manner would be equally prompt. He carried the murderous tooth to an intelligent physician, explained its operation, and begged him to have an instrument made by which morphine and other medicines might be similarly applied for the relief of human suffering. The doctor smiled at his rustic simplicity, but now he would consider himself everlastingly disgraced if he should be caught without a hypodermic syringe and a little phial of morphine and atropine in his vest pocket.

I mention these facts not only to illustrate the importance of your paying attention to little things, but to warn you not to reject an apparently reasonable suggestion without proper investigation, no matter from what source it may come. The leading principles taught by "the great father of medicine" himself were those of rational empiricism. He neither attempted nor pretended to form his theories from *a priori* reasoning, but made a careful study of the phenomena of nature, and from them deduced such conclusions as those phenomena seemed to justify.

The celebrated Cornelius Celsus, the contemporary, if not an associate, of Horace and Ovid, although a follower of Hippocrates and Asclepiades, was not a blind adherent of any sect. He did not hesitate to dissent from the views of his illustrious prototypes where he thought they were in error, and accepted with equal impartiality whatever he found to commend, whether in the teachings of the Empirics, the Dogmatics, the Methodics, or the Eclectics; and the immortal Claudius Galenus himself, the most distinguished and the most esteemed of all the ancient apostles of medical science, while strenuously maintaining the superiority of theory over mere empiricism, blended in his own school the empirical knowledge he had derived from the teachings of Satyrus, Stratonicus, and Eschrion. In short, the man who makes himself truly great in any calling is the one who has sense enough to know a good thing when he sees it, and decision of character enough to make it useful whenever he may find it.

Whatever you may accomplish, however, in your professional career, you should make up your minds not to be surprised to find yourselves deprived of much of the credit that may be justly due you. In your profession, as in all others—

> "Full many a flower is born to blush unseen,
> And waste its sweetness on the desert air,"

while, on the other hand, full many a name shines upon the envied page of history with a borrowed light to which it is not entitled, and which its owner himself would not pretend to claim.

Both of these ideas are illustrated, to some extent, in the present fame of the celebrated William Harvey. If that illustrious man could return to the earth to-night he would probably be astounded to find himself regarded by millions of people, including a large majority of even the more intelligent classes, as the first discoverer of the mere movement of the blood in the human body, a fact familiar to thousands from the earliest antiquity. He was not even the first to suggest the idea of its circulation, which, it is said, was, at least remotely, conjectured by the immortal Stagirite himself, and still more distinctly by Mondino, Berenger, and others of more modern times. Whether it was observed by the great Vesalius or not, we have no means of knowing, but it is certain that the leading outlines, not only of the pulmonary but the larger circulation, were taught by his friend and successor, the ill-fated Michael Servetus, more than fifty years before Harvey was born; and still more clearly by others, especially by Harvey's preceptor in anatomy—Fabricius—who pointed out to his pupil the valves in the veins of the extremities, and set his inquisitive mind to investigating their office. If he could stand where I stand and speak to you as I do to-night, he would tell you that he only did what some of you may yet do with respect to some other important but unsettled question in your profession—that he was not willing to sit down, content with what others had ascertained, but that he gathered up all the facts already known, improved upon the knowledge of his predecessors, and, by a series of patient, intelligent, and carefully-conducted experiments, elaborated an already existing theory, and demonstrated its truth to the exclusion of a doubt.

I have alluded to the example of this famous physician, however, more especially to emphasize the important truth that, without a certain degree of dissatisfaction with the existing condition of professional learning, coupled with a passionate disposition for honest, earnest, independent, and intelligent inquiry, anything like progress in medical science is an impossibility. It is universally admitted that among all the brilliant names that illustrate the earlier annals, if not the entire history of your profession, that of Galen stands pre-eminent. Yet it would have been far better for the human family, perhaps, if Galen had never been born.

The blind, abject, almost idolatrous deference of his successors to his teachings, with all their crudities and absurdities, postponed everything like genuine progress in scientific medicine for centuries. They regarded his writings as the ultimate authority from which there could be no appeal, and rejected with disdainful scorn whatever appeared to be inconsistent with his *dicta*. In their vain attempts to reconcile the theories of their master with the phenomena of Nature, they had but little time to interrogate Nature herself, and still less inclination to pursue the study of medical science in those fields in which it can be followed with any assurance of success. Eschewing everything like originality of thought or independence of inquiry, they went on for more than five hundred years, stifling intelligent investigation and killing their patients according to the most approved methods of Galenian science.

I would warn you, however, that if it should be your fortunate lot to make any great discovery or improvement in the practice of your chosen art, or any very remarkable contribution to medical science, you should be prepared for a general howl of dissent from the less profound and more

pretentious of your professional brethren until it shall have received the approbation of their acknowledged leaders. I am not fully prepared to believe that the man who first suggested the practicability of carrying corn in both ends of the bag when going to the mill, instead of the old practice of putting a rock in one end to balance the corn in the other, was actually mobbed by his indignant neighbors as a dangerous revolutionist; but I suppose it is really true that Galileo barely escaped a sound roasting for expressing the opinion that the earth moved around the sun, and not the sun around the earth. It is a fact, at any rate, that the disturber of ancient prejudices or long-accepted opinions generally raises a storm about his head, and nowhere has that truth been more frequently or more strikingly illustrated than in the history of the medical profession.

When Galen, at the solicitation of many of the most distinguished philosophers and men of rank, commenced a course of lectures in the Imperial City upon the anatomy of the human system, the novelty of his teachings and the bold contempt with which he assailed the long-accepted fallacies of his predecessors raised such a tempest of indignant criticism among his professional rivals that he was not only compelled to abandon the rostrum, but to get out of Rome. And when Vesalius, in the sixteenth century, defied the authority of Galen, which was still considered supreme, and destroyed by actual demonstration the credit of nearly all the learning to which the earlier masters had pretended; when he swept away the long-venerated rubbish of ancient error and laid the immutable foundation upon which the splendid fabric of modern medical science has been reared, he brought upon himself a perfect deluge of virulent reproach from even the most distinguished of his professional contemporaries. And you will perhaps be surprised to learn that among the foremost of his detractors was the celebrated Falloppius, concerning whom, I have no doubt, you have heard a good deal from your diffident but distinguished dean, unless his lectures have been too much abridged by his characteristic taciturnity.

When Harvey first published to the world his beautiful demonstration of the true theory of the circulation of the blood, it is said that there was not a single physician over forty years of age, either in Great Britain or on the Continent, who coincided with his views. On the contrary, his practice fell away from him, and he was for years the object of the extremest obloquy and abuse. Nor was it until after his experiments had been repeated, and his observations indorsed by many of the most eminent anatomists and physiologists of the period, that his theory was accepted by the far more numerous class of his brethren who were profound in nothing but their ignorance of scientific truth, and their conceit of their own professional culture and ability.

And so when Dr. Ephraim McDowell published his modest account of his first ovariotomy, some eight years after it was performed, it was denounced as a falsehood, and its author held up by the leading medical and surgical writers of the day as a liar and an impostor; and it was not until ten years after that the learned editor of the London *Medico-chirurgical Review*, who had been one of his most malignant satirists, had the grace to thank God that he had lived to ask pardon of the great pioneer surgeon of Kentucky for the injustice he had done him.

It is an ill wind, however, that blows nobody any good; and it is probable that the world is indebted to the intolerance of the medical profession during the fifteenth and sixteenth centuries toward any improvement or innovation in their own peculiar department of learning for the initial step in the wonderful development of astronomical science which has taken place since that period. About the year 1500 a German physician, becoming disgusted with the bigoted deference to the doctrines of the earlier masters, which seemed to render any advancement in the philosophy or practice of his profession an impossibility, abandoned it and devoted himself to the study of mathematics. He soon detected the absurdities of the Ptolemaic hypothesis concerning our system of planets, and revived the theory of Pythagoras that the sun was the center of a series of spheres, including our earth, which revolved around it, and also upon their respective axes. For thirty years he labored on the demonstration of that sublime truth, and to-night the name of Nicholas Copernicus, the great prototype of Kepler, Galileo, Newton, Herschel, and Leverrier, remains written upon the star-decked vault of heaven in characters of ineffable glory, to be hymned by the spheres as long as they shall continue in their wondrous pathway through the skies.

I hope I have made myself clearly understood in urging upon you the importance of thinking and investigating for yourselves. Mark me: I would by no means advise you to tamper with the health or trifle with the lives of your patients by reckless or questionable experiments; far from it, indeed. You had infinitely better confine yourselves to catnip, comfrey, and elecampane for the sake of your own consciences as well as for their safety. I simply mean that, while you should act prudently, you should act independently; that you should not regard everything you see in the text-books as absolutely infallible, nor reject anything because it may not be backed by the *ipse dixit* of some recognized authority in the profession.

John of Salisbury, one of the most celebrated scholars and among the wittiest writers of the twelfth century, has left us a sketch, in his *Polycraticon*, of the average medical graduate of his period, which I beg leave to read to you, in order that you may see the immense difference between them and some of the newly-fledged physicians of the present enlightened day. He says:

"They return from college full of flimsy theories to practice what they have learned. Galen and Hippocrates are continually in their mouths. They speak aphorisms on every subject, and make their hearers stare at their long, unknown, and high-sounding words. The good people believe that they can do anything because they pretend to all things. They have but two maxims which they never violate—never mind the poor; never refuse money from the rich."

We find an occasional survivor of this species even in our own age, and if there is one of you who has made up his mind to prostitute his sublime profession solely to the

sordid purpose of accumulating lucre he will be certain to take his place among them, and you will soon find him resorting to all the artifices of the knavish quack in order to magnify his own importance and to multiply his chances for "gathering gainful pillage."

On a county court day, when the streets are full of country folk, he will rush out of his office, fling his pill-bags across his saddle, mount his horse, and gallop off on a supposititious call, as though life or death depended on his speed; and, after an hour or two, he will come galloping back again, run into his office, rush out again and scurry away in the opposite direction. He will be a prompt attendant of the most popular church in town, where he will sit "as demure as a harlot at a christening" until some impecunious emissary, whom he has hired for a trifling consideration to do so, hurries in with a most anxious expression on his countenance and calls him out just as the service has reached its most solemn point.

If he should happen to perform some trifling operation in minor surgery, he will have it paraded in the local newspaper as one of the most astonishing feats of the scalpel since the days of Antyllus or Heliodorus; but if he should venture beyond his depth, and cut off the wrong leg, or have his victim die under the knife, he will contrive to have as little said about it as possible, and satisfy the community that the patient's death was only a question of time anyway.

While constantly parading exaggerated accounts of his own superior learning and skill, he will lose no opportunity to injure his absent rival by insidiously depreciating his merits or openly misrepresenting him behind his back. If he should be called to a patient in the absence of the family physician, he will not fail to pronounce the medicine which the doctor has left a deadly poison, and then prescribe the same thing under another name. If a consulting physician should say, in the presence of the patient, that he might safely rely upon the "*vis medicatrix naturæ*," he will whisper to some officious friend of the sick person standing by: "That will kill him quicker than strychnine." In speaking with one of the unlettered multitude about his practice, he will never use a term his hearer will be likely to understand, if he can think of a technical synonym of "learned length and thundering sound." He will never prescribe such a thing as a common poultice, but will recommend a cataplasm of certain ingredients. He will not even suggest a wash of ordinary salt and water; it must be a saturated solution of sodium chloride. As I have already said, however, I am happy in the conviction that none of the gifted and aspiring young men whom I have the honor to address to-night will ever condescend to the low artifices or be content with the degraded level of the vulgar sham, the mere knavish pretender.

Mr. Sergeant Balentyne, the celebrated English barrister, on being asked what was the highest qualification for a Lord Chief-Justice, replied that "a Lord Chief-Justice should, in the first place, be a gentleman, and then, if he should know a little law, it would be so much the better." And so I would say, while it may be necessary in the practice of your profession that you should know something about medical science, it is absolutely indispensable that you should be gentlemen! By this I do not mean that you should simply cultivate the graces and practice the ordinary amenities of courteous intercourse common to polite society, but that you should at all times, and under all circumstances, illustrate the heaven-inspired virtues of honest, earnest, noble Christian men. That you should spurn with indignant scorn the low, mean vices of envy, malice, and evil speaking, and never suffer yourselves to be betrayed into anything that can degrade your manhood or cast the slightest stain upon the bright escutcheon of your honorable profession. Above all things, let your demeanor toward your professional brethren be candid, manly, and just, and your deportment to your patients kind, considerate, and conscientious.

I feel that I owe you an apology for having detained you so long, but while I bid you the heartiest Godspeed in your chosen career, I trust you will permit me to hope that if you shall at some time in the great unexplored future that lies before you recall a single word I have spoken, by which you have been comforted or encouraged in the attainment of the success to which you aspire, you will not regret the courteous attention you have given me, and for which I tender you my profoundest thanks.

A REPORT OF SIXTY-TWO CASES OF HIP DISEASE

*Observed in the Practice of Hugh Owen Thomas, of Liverpool.**

By JOHN RIDLON, M. D.,
ASSISTANT SURGEON AT THE VANDERBILT CLINIC, NEW YORK.

With a desire to present for your consideration further facts regarding the use of the Thomas hip splint, I spent twelve days during the month of June of this year in Liverpool, and examined all the cases of hip disease coming under the observation of Mr. Thomas during that time.

It had been my desire to make a report upon cured cases, but I found that no records of cases had been kept, and that even the names and addresses of patients were wanting. I therefore contented myself with taking all cases as they came, not with the idea of showing ultimate results, but rather the presenting of a picture of Mr. Thomas's daily work. New cases will be presented; cases where the treatment has just been commenced; cases that have been under treatment one and two years; cases that have been under treatment five and six years; cured cases; cases among the poor and among the well-to-do; and cases that have done badly and cases that have done well. I realize, as must every one else, that a much more brilliant showing would have been made had only cured cases been considered; but it is not to make a brilliant showing that I present this re-

* Read before the American Orthopædic Association, September 18, 1890.

port; my only desire is to present to you the facts as I found them.

Every opportunity was given me by Mr. Thomas to question and examine the patients; and the facts which I shall present to you were obtained from the patients themselves, or their parents, and the measurements were all made by me.

Statements as to the degree of deformity present when treatment was commenced, and as to the length of time spent in bed, I found to be so uncertain that they have been omitted; and I have contented myself with recording only the time from the beginning of the limp or pain, or both, to the commencement of treatment; the time which the long splint was worn; the time which the short splint was worn; the time since treatment was discontinued, in cured cases; the presence or absence of abscesses, and, if present, when they appeared and how many, and the sinuses remaining; and the presence or absence of pain. The examination consisted of inspecting the patient as to his general condition; noting the presence of abscesses, sinuses, and cicatrices of sinuses; flexing the sound leg on the chest while the affected leg was held in full extension; measuring the length of the legs and the degree of flexion and of abduction or adduction; and testing the motion in those cases where the splint was for any cause removed. The standard position taken for measuring flexion was that which is known as "Thomas's flexion-test position"—that is to say, the sound leg is flexed on the chest to such a degree that the elbow can be hooked through the flexure of the knee, the anterior surface of the elbow being in contact with the popliteal space, and the forearm at right angles across the body. This position effectually overcomes all lordosis, and in some cases gives a lumbar kyphosis, so that if the affected leg can be carried down to the table, the patient, of course, being supine, it shows that the joint is free from all flexion, and that extension to a certain degree is possible. With the patient then in the flexion-test position, the angle of flexion was measured after the plan of Dr. Kingsley, of Boston.* In those cases where motion was not tested, because the patient was not removed from the splint, if the sound leg could be flexed on the chest to the flexion-test position while the affected leg was confined in the splint, the popliteal space resting on the table, it was considered as being free from flexion, and so noted. It will be found that in all cases where flexion is present, or where any special joint tenderness remains, it will either be impossible to flex the sound leg to the flexion-test position, or very painful; and that involuntary muscular spasm can be as readily detected as on manipulating the affected leg. I have on that account noted whether there was present or absent tenderness on flexing the sound leg into the flexion-test position. The terms "real" and "apparent" shortening or lengthening are used in the same sense as suggested by Dr. Lovett,† of Boston, and the abduction or adduction is calculated by Dr. Lovett's table.

Sixty-two cases of unilateral hip disease were seen and examined. Four of them (I, II, III, IV) were new cases and are recorded simply to show the condition of cases when they present for treatment. They are omitted from all the calculations excepting that of the average duration of the limp before commencement of treatment.

The three cases, to wit, XXXIII, LX, LXI, were in children in well-to-do families, and had received the care that we are accustomed to expect in private cases. It is not surprising, then, to find that in these cases the results are better than the average in the other cases. All the remaining cases were from among the poorer classes, who, from ignorance and poverty, had received no better care than the dispensary class receive with us. Indeed, many of them were charity cases, and the sum total which these patients pay to Mr. Thomas for splint and treatment is, I have no doubt, no greater than dispensary patients with us are accustomed to pay for the traction hip-splint, and in many cases not as much. It should, therefore, be evident that any assumption that Mr. Thomas ought to get better results than have elsewhere been reported, because his patients are private patients, is unfair.

The average duration of limp before treatment was commenced in these sixty-two cases was a little over ten months.

The average duration of treatment was not computed, as only a few were cured cases, and as many had been under treatment but a short time.

The "long splint" referred to is that which is ordinarily known as the Thomas splint, and extends from the lower angle of the scapula to the lower third of the leg. The "short splint" is the long splint cut off, and not extending below the knee. Contrary to what we have been taught, it was found that the long splint had not always been put on at the beginning of treatment, but that the short splint, which "does not lock the knee," had been put on instead. In some cases the short splint had been replaced later by the long splint, but in other cases its use had been continued throughout the entire course of treatment. Contrary, also, to what we have been taught, nearly all of these children were found walking around without high patten and crutches. In the same way patients were allowed to walk before the deformity had been overcome, and while muscular spasm and deformity, and sometimes pain, still persisted.

Of the 58 patients that had been under treatment for a longer or shorter time, 24 had shortening, 24 had adduction, 5 had abduction, 3 had inward rotation, and 2 had outward rotation. In the cases where abduction coexisted with shortening the abduction was an advantage, as it compensated in a measure for the shortening.

Of the 24 patients who had real shortening, 2 had $\frac{1}{4}$ inch, 9 had $\frac{1}{2}$ inch, 4 had $\frac{3}{4}$ inch, 3 had 1 inch, 4 had $1\frac{1}{2}$ inch, 1 had 2 inches, and 1 had $2\frac{1}{2}$ inches. In 2 cases the affected leg was actually longer than the other leg.

One patient had in-knee, apparently resulting from the action of the adductor muscles of the thigh, while the ankle was held by the splint and the knee was not. It should be noted that this patient was walking around without patten and crutches, while there still remained a very tense involuntary spasm of the adductor muscles.

Of the 58 cases, 23 had, at some time during their

* G. L. Kingsley, *Boston Med. and Surg. Jour.*, July 5, 1888.

† R. W. Lovett, *Boston Med. and Surg. Jour.*, March 8, 1888.

course, some before, but many after treatment had been commenced, presented one or more abscesses. Of these, one had disappeared without opening and another was fast disappearing.

In 31 cases the motion was not tested, for the reasons above stated. In 27 it was tested; 12 patients had no motion, 10 had some motion, 2 had motion to ninety degrees, and 3 had normal motion. It should be borne in mind that these 27 cases in which motion was tested were either cured cases, or so well advanced in convalescence that it was not thought in any way a risk to test the motion very thoroughly; while of those not tested it would seem probable that very many would have shown considerable motion, inasmuch as they showed free flexion of the well leg to the flexion-test position; or, in other words, they showed normal extension of the affected limb.

All these patients, unless otherwise so stated, were in good general health.

The record of the cases is as follows:

Case I.—Female, fifteen years old; has limped at times and complained of some pain for three years. There is involuntary muscular spasm and flinching on manipulating the leg, but there is no deformity, and the patient can be put in the "Thomas flexion-test position" without pain or any special effort. Mr. Thomas refused to commence treatment without further observing the case.

Case II.—Female, twelve years old; limped for six months; no complaint of pain; no night cries; no abscess; general condition fairly good; one inch real, but only a quarter of an inch apparent shortening; abduction, six degrees; flexion, twenty degrees; some motion in flexion; well-marked involuntary muscular spasm. Hip splint now applied.

Case III.—Female, eight years old; limped for three months before treatment was commenced; long splint applied at the Liverpool Infirmary two months ago; now seen by Mr. Thomas for the first time; an abscess has been noticed for the past week; no pain; no tenderness on flexing the sound leg to the flexion-test position; no abduction; no adduction; some motion in all directions, limited by muscular spasm.

Case IV.—Female, eleven years old: began to limp nine months ago; a splint was put on six months ago by a Manchester surgeon, but it is too flexible to be of any use; patient now seen by Mr. Thomas for the first time; abscess noticed two weeks ago; has some screaming in sleep, but no pain otherwise; some tenderness on palpation and manipulation; muscular spasm well marked; no real shortening; half an inch apparent shortening; adduction, four degrees; flexion, thirty-nine degrees; very little motion in any direction. A new splint was applied.

Case V.—Female, nine years old; has limped at times for four years; has not complained of pain; no abscess; muscular spasm well marked; very little tenderness on gentle manipulation; leg one quarter of an inch longer than the leg of the opposite side; flexion, thirty degrees; no abduction; no adduction; very little motion in any direction; splint now applied for the first time. I saw the patient again at the end of a week. The flexion had been completely reduced and there had been no pain.

Case VI.—Male, nine years old; limp and some pain for four months before treatment was commenced; has worn long splint one week; has swelling in the groin, but fluctuation is doubtful; has night cries; tenderness on flexing the sound leg to the flexion-test position; marked muscular spasm; has not yet been allowed to walk; no shortening; no flexion; no abduction; no adduction; motion not tested.

Case VII.—Male, six years old; limp and pain for six months before treatment was commenced; has worn long splint for ten weeks; still has some night pain, but is allowed to walk without crutches; no abscess; some tenderness on flexing the sound leg to flexion-test position; no real, but half an inch apparent shortening; adduction, four degrees; no flexion; motion not tested.

Case VIII.—Male, three years and a quarter old; has never walked; when three months old had a fall, and splint was put on at once at the Liverpool Infirmary and was worn for a year; then came under care of Mr. Thomas, and has continued to wear the splint for two years more; no abscess; no pain for a long time past; no tenderness on flexing the sound leg to the flexion-test position; no real shortening; two inches apparent shortening; adduction, twenty-one degrees; no flexion; motion not tested.

Case IX.—Female, twelve years old; limped for six months before treatment was commenced; has worn long splint for nine months; no abscess; no tenderness on flexing the sound leg to flexion-test position; no real shortening; an inch and three quarters apparent shortening; adduction, fourteen degrees; no flexion; considerable inward rotation; motion not tested.

Case X.—Male, four years old; limp and pain for nine months before treatment was commenced; has worn long splint twelve months; an abscess appeared soon after splint was applied, and is now near breaking; no pain now; no tenderness on flexing the sound leg to flexion-test position; no real shortening; an inch apparent shortening; adduction, nine degrees; no flexion; motion not tested.

Case XI.—Male, four years old; limped for three weeks before treatment was commenced; has worn the long splint for sixteen months; some thickening in the groin, but no fluctuation can be made out; no pain; no tenderness on flexing the sound leg to flexion-test position; a quarter of an inch real and an inch and a quarter apparent shortening; adduction, nine degrees; no flexion; motion not tested.

Case XII.—Female, fourteen years old; limped for nine months before treatment was commenced; wore splint for six months before coming to Mr. Thomas, and has continued to wear the long splint for eight months since; abscess was present when she first came under the care of Mr. Thomas; it has never opened, and has now for some time been growing smaller; suffered great pain and could not walk for a long time; no pain now; no tenderness on flexing the sound leg to flexion-test position; half an inch real and an inch and a half apparent shortening; adduction, seven degrees; no flexion; motion not tested.

Case XIII.—Male, six years old; limped for two weeks before treatment was commenced; has worn long splint eight months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; no real shortening; three quarters of an inch apparent shortening; adduction, seven degrees; no flexion; motion not tested.

Case XIV.—Female, six years old; limp and pain for six months before treatment was commenced: has worn long splint two weeks; was unable to walk for the last week before the splint was applied; no abscess; no pain now; some tenderness on flexing the sound leg to flexion-test position; half an inch real and an inch apparent shortening; adduction, four degrees; no flexion; motion not tested.

Case XV.—Male, thirty years old; limped for five years before treatment was commenced; has worn short splint three years; has had eight abscesses; one sinus remains; no pain now; no tenderness on flexing the sound leg to flexion-test po-

sition; two inches real but only an inch apparent shortening; abduction, six degrees; no flexion; no motion.

Case XVI.—Female, four years old; limped for three months before treatment was commenced; has worn long splint for six months; abscess, noticed four months ago, broke two days ago; has no pain; no tenderness on flexing the sound leg to flexion-test position; no real shortening; half an inch apparent shortening; adduction, four degrees; no flexion; some motion.

Case XVII.—Male, eleven years old; limp and pain for six months before treatment was commenced; wore short splint for two months; since then has worn long splint for twenty months; abscess appeared four months after treatment was commenced, but disappeared without aspiration or opening; no pain; no tenderness on flexing the sound leg to flexion-test position; an inch and a half real shortening, but only three quarters of an inch apparent shortening; abduction, five degrees; no flexion; motion not tested.

Case XVIII.—Female, fifteen years old; limped for five months before treatment was commenced; has worn the long splint fifteen months; no abscess; no pain on flexing the sound leg to flexion-test position; half an inch real shortening; half an inch apparent lengthening; abduction, seven degrees; no flexion; motion not tested.

Case XIX.—Male, twenty-one years old; limped for two years before treatment was commenced; wore long splint three years; after going without splint for twelve months an abscess formed, opened spontaneously, and discharged for six months; during this time a short splint was applied, and has now been worn eighteen months; no pain; no tenderness on flexing the sound leg to flexion-test position; an inch and a half real, but only half an inch apparent shortening; abduction, six degrees; no flexion; some motion.

Case XX.—Male, four years and a half old; is a remarkably large child for his age; limped for twelve hours before treatment was commenced; has worn long splint for two months; no abscess: no pain; no tenderness on flexing the sound leg to flexion-test position; no real shortening or lengthening; half an inch apparent lengthening; abduction, four degrees; no flexion; motion not tested.

Case XXI.—Male, seven years old; was hurt by a cricket-ball five weeks before treatment was commenced; has worn long splint fourteen months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; no real shortening or lengthening; half an inch apparent lengthening; abduction four degrees; no flexion; motion not tested.

Case XXII.—Male, five years old; limp and pain at times for two months and a half before treatment was commenced; has worn long splint for two months; no abscess; no pain; slight tenderness on flexing the sound leg to flexion-test position; no real shortening; half an inch apparent shortening; adduction, four degrees; no flexion; some inward rotation; motion not tested.

Case XXIII.—Female, four years old; having been cured without deformity or stiffness, relapsed two years after treatment had been discontinued, and has now been wearing short splint two months; one cicatrix; no pain; no tenderness on flexing the sound leg to flexion-test position; no shortening; adduction, four degrees; no flexion; no rotation; slight motion.

Case XXIV.—Male, ten years old; limp and pain for six weeks before treatment was commenced; has worn long splint for six years; has had three abscesses, from which two sinuses remain, and another abscess broke into the intestine; had albuminuria for many months, and was in a very precarious condition; no albuminuria now; is fat and in good color; no pain for a very long time; half an inch real and two inches apparent shortening; adduction, sixteen degrees; no flexion; no motion. Has walked about for a long time without patten and crutches.

Case XXV.—Male, six years old; limped for three months before treatment was commenced; has worn long splint eighteen months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; slight motion in all directions.

Case XXVI.—Female, eleven years old; limp and pain for two years before treatment was commenced; wore long splint for two years; has worn short splint for one year; no abscess; no pain for a long time; no real shortening; one inch apparent shortening; adduction, eight degrees; flexion, twenty-five degrees; no motion.

Case XXVII.—Male, two years old; has had trouble since birth; long splint was put on when four months old; it has been very difficult to keep patient properly in the splint, and he runs about constantly; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; half an inch shortening; no abduction; no adduction; no flexion; some motion in all directions.

Case XXVIII.—Male, nine years old; limp and pain for seven months before treatment was commenced; wore long splint for three years; has worn short splint two years; abscess four years ago, and another three years ago; no sinuses; no pain; no tenderness on flexing the sound leg to flexion-test position; three quarters of an inch real and two inches apparent shortening; adduction, ten degrees; flexion, twenty-two degrees; no motion. Lives far away and has been seen but once in three months. He has walked about without patten and crutches.

Case XXIX.—Male, fifteen years old; limp and pain for seven years before treatment was commenced; father is consumptive; wore long splint two years; has worn short splint one year; had one abscess before treatment was commenced; no pain; no tenderness on flexing the sound leg to flexion-test position; patient has grown very rapidly and is a very tall boy for his age; an inch and a half real shortening, two inches apparent shortening; adduction, four degrees; no flexion; some motion in all directions.

Case XXX.—Male, seven years old; limped for four months before treatment was commenced: wore long splint fifteen months; has worn short splint twelve months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; half an inch real and an inch and a half apparent shortening; adduction, four degrees; flexion, twenty degrees; no motion.

Case XXXI.—Female, nine years old; strained joint skipping rope; limped and had pain at times for three years and a quarter before treatment was commenced; was kept in bed one month before the splint was applied; wore long splint eighteen months; has worn short splint for eighteen months; no abscess; no pain for a long time; no tenderness on flexing the sound leg to flexion-test position; quarter of an inch real and three quarters of an inch apparent shortening; adduction, four degrees; no flexion; some motion.

Case XXXII.—Female, ten years old; limped for four months before treatment was commenced; has worn long splint for ten months; has in-knee of eight weeks' duration, resulting from the use of the splint; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; shortening and the consequent adduction not measured because of the in-knee; no flexion; motion not tested.

Case XXXIII.—Female, eight years old; limp and some pain for three weeks before treatment was commenced; has worn short splint for three months; never has worn long splint,

but has not been allowed to walk; no abscess; no pain since treatment was commenced; no shortening; no flexion; no adduction; no abduction; normal motion in all directions; now to be allowed to walk with crutches.

Case XXXIV.—Male, forty-two years old; limp and pain for twelve months before treatment was commenced; no traumatic cause; has never worn the long splint; has worn short splint for three months; no abscess; no tenderness on flexing the sound leg to flexion-test position; no pain; no shortening; no flexion; no adduction; no abduction; no rotation; motion not tested.

Case XXXV.—Male, sixteen years old; limped for five weeks before treatment was commenced; has worn long splint for nine months; deep fluctuation in groin; still has some pain; some tenderness on flexing the sound leg to flexion-test position; three quarters of an inch real shortening; no abduction; no adduction; no flexion; motion not tested.

Case XXXVI.—Female, nine years old; limped for twelve months before treatment was commenced; has worn long splint twelve months; small area of deep fluctuation in front of the joint; no pain; no tenderness on flexing the sound leg to flexion-test position; no real shortening; half an inch apparent shortening; adduction, four degrees; no flexion; motion not tested.

Case XXXVII.—Male, fourteen years old; limp and pain for three months before treatment was commenced; has worn long splint for two years; two sinuses in the groin for the past eighteen months; no pain now; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; no motion.

Case XXXVIII.—Male, eight years old; limped for fourteen months before treatment was commenced; has worn long splint for ten months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; some motion.

Case XXXIX.—Female, eight years old; limp and pain for twelve months before treatment was commenced; has worn long splint three years; first abscess ten months after treatment was commenced, and second soon after first; two sinuses remain; no pain; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; motion not tested.

Case XL.—Male, twenty months old; pain and stiffness for six weeks before treatment was commenced; has worn long splint ten months; one abscess opened spontaneously three months ago; sinus remains; another abscess now present pointing in two places; no pain; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; motion not tested.

Case XLI.—Male, thirteen years old; limp and pain for one year before treatment was commenced; has worn long splint a year and a half; first abscess opened twenty months ago, and a second three months ago; one sinus remains; no pain now; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; motion not tested.

Case XLII.—Female, fourteen years old; limped for three months before treatment was commenced; never wore long splint; has worn short splint four months; had one abscess; no sinus; has had disease, with abscess at right elbow, for eight months; no pain now; some tenderness on flexing the sound leg to flexion-test position; general condition fairly good; no real shortening; three quarters of an inch apparent shortening; adduction, three degrees; no flexion; motion not tested.

Case XLIII.—Male, thirteen years old; limped for three weeks before treatment was commenced; wore long splint for six years; has worn short splint for two years and a half; was in Liverpool Infirmary nine months at commencement of treatment, not under Mr. Thomas; has had three abscesses; the last closed three years ago; all appeared while under the care of Mr. Thomas; an inch and a half real shortening; no abduction; no adduction; no flexion; some outward rotation; motion not tested.

Case XLIV.—Female, eleven years old; limp and pain for two years before treatment was commenced; wore long splint for two years; has worn short splint for one year; an abscess opened spontaneously at about the time treatment was commenced; it closed after discharging for abont a year; no pain since that time; no tenderness on manipulation; one inch real shortening; no abduction; no adduction; no flexion; no motion.

Case XLV.—Female, nine years old; limped for four months before treatment was commenced; wore long splint for ten months; has worn short splint two months; when three years old wore a Thomas splint, but not under Thomas's care, for ten months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; some motion in all directions.

Case XLVI.—Male, twenty years old; suddenly attacked with pain and limping one month before treatment was commenced; no traumatism; has worn long splint ten months; no abscess; no pain now; no tenderness on flexing the sound leg to flexion-test position; one inch shortening; no abduction; no adduction; no flexion; no motion.

Case XLVII.—Male, twenty-one years old; limped for twelve months before treatment was commenced; wore long splint for eighteen months; has worn short splint for four years; abscess opened spontaneonsly before treatment was commenced and still discharges; no pain; no tenderness on flexing the sound leg to flexion-test position; one inch shortening; no abduction; no adduction; no flexion; motion not tested.

Case XLVIII.—Male, six years old; limped for two days before treatment was commenced; wore long splint for two years; has worn short splint three months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; three quarters of an inch real and one inch and three quarters apparent shortening; adduction, nine degrees; no flexion; motion not tested.

Case XLIX.—Male, six years old; limped for three months before treatment was commenced; has worn long splint for two years; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; leg one quarter of an inch longer than well leg; no abduction; no adduction; no flexion; motion not tested.

Case L.—Female, eight years old; limped for four months before treatment was commenced; has worn long splint twelve months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no addnction; no flexion; no motion.

Case LI.—Male, three years old; limped for five weeks before treatment was commenced; has worn long splint fourteen months; no abscess; no pain; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; motion not tested.

Case LII.—Female, five years old; limp and crying in sleep for two weeks before treatment was commenced; has worn long splint two months; no abscess; still has crying in sleep, but does not complain of other pain; some tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; motion not tested.

Case LIII.—Male, six years old; limped for six weeks before treatment was commenced; has worn long splint for one week; no abscess; no pain; no tenderness on flexing the sound

leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; motion not tested.

Case LIV.—Male, four years old; limp and some pain for three years before treatment was commenced; has worn long splint for three months; no abscess; no pain of late; no tenderness on flexing the sound leg to flexion-test position; no shortening; no abduction; no adduction; no flexion; motion not tested.

Case LV.—Female, eleven years old; limp and pain for six months before treatment was commenced; wore long splint four years; has now been without treatment for two weeks; no abscess; no pain; no tenderness on manipulating leg; no shortening; adduction, two degrees; no flexion; slight inward rotation; no motion.

Case LVI.—Male, seventeen years old; twisted hip in kicking a foot-ball, and was seen next day; was kept in bed three months without any mechanical treatment; then had the long splint for one year, and the short splint for two years; has had no treatment for the past six months; no abscess; no pain for a long time; pain was very great for a long time at the commencement of the trouble; no tenderness on manipulating the leg; no shortening; no abduction; no adduction; no flexion; normal motion in all directions.

Case LVII.—Male, twenty-two years old; limp and pain for six months before treatment was commenced; wore long splint for three years and a half; no pain for a long time; cicatrices of six sinuses present; has been without treatment for four months; no tenderness on manipulating leg; three fourths of an inch real shortening; one inch and a quarter apparent shortening; adduction, eight degrees; flexion, thirty-one degrees; no motion.

Case LVIII.—Male, three years old; limped for two weeks before treatment was commenced; wore long splint thirteen months; no treatment for past three months; no abscess; no pain; no tenderness on manipulation; no shortening; no abduction; no adduction; no flexion; considerable outward rotation; all motions, except inward rotation, smooth and free to ninety degrees.

Case LIX.—Male, twenty-two years old; limped for five years before treatment was commenced; wore long splint two weeks; wore short splint four years and four months; no treatment for past four months; no abscess; no pain now; no tenderness on flexing the sound leg to flexion-test position; two inches and a half shortening; great trochanter two inches and a half above Nélaton's line; no abduction; no adduction; no flexion; no motion.

Case LX.—Female, twelve years old; limped for three months before treatment was commenced; wore long splint two years; had five abscesses; no treatment for past three years; half an inch shortening; no abduction; no adduction; no flexion; some motion in all directions; walks with scarcely any limp, and can go up and down stairs without difficulty.

Case LXI.—Male, eight years old; limped for four months before treatment was commenced; wore long splint two years and a half; has had no treatment for past year; no abscess; no muscular spasm; no shortening; no abduction; no adduction; no flexion; free motion in all directions to ninety degrees; runs and walks without limp or inconvenience.

Case LXII.—Female, twenty years old; limp commenced one year before treatment; became unable to walk and suffered great pain; had hæmorrhages from the lungs; wore long splint three years; no treatment for past twelve months; general condition excellent; no pain now; no tenderness on manipulation; half an inch shortening; no abduction; no adduction; no flexion; normal motion in all directions.

From a study of these cases conclusions can not properly be drawn; but, as I have probably given them a more careful consideration than any one else ever will, I will venture the following suggestions:

Very many of these patients that have had the short splint applied before muscular spasm and pain had subsided and before deformity had been reduced, that have been allowed to walk around without high patten and crutches—that is to say, those whose joints have only been partially immobilized, without being protected from the pressure of superincumbent weight and the concussion of walking—present a moderate degree of adduction, absence of motion, and, in a few cases, slight flexion, and in one instance in-knee.

On the other hand, those patients that have worn the long splint until cured, that have remained in the horizontal position until all pain and muscular spasm had subsided, and had then used the high patten and crutches and had had the benefit of intelligent care and nursing, have been cured without flexion or other deformity than the shortening due to actual bone erosion and arrested growth, and they have shown motion in a very large proportion of cases and in not a few has there been normal motion.

The absence of any traction force, either in the line of the shaft or of the neck of the femur, does not seem to have increased the number of patients having abscesses or the number of abscesses in each case, nor to have increased the frequency of shortening or the amount of shortening in each case. No case has given any signs of perforation of the acetabulum by the head of the femur, and in only one has there been any indication of perforation by suppuration. And involuntary muscular spasm and pain arising therefrom are noticeable for their absence. In a word, those patients who have had no traction are found to be remarkably free from all those conditions which we have been taught can only be relieved by persistent and long-continued traction.

In conclusion, nothing appears to indicate that the principles upon which Mr. Thomas has based his teaching are in any way at fault, though in practice there is still somewhat to be desired.

337 West Fifty-seventh Street.

THE INFLUENCES OF CLIMATE IN THE UNITED STATES OVER BRIGHT'S DISEASE.

By CHARLES W. PURDY, M. D.,
CHICAGO.

In attempting a systematic study of the influences exerted by climate over special forms of disease, the value of the results obtained will depend largely upon the geographical extent and variation of the territory considered. It is, furthermore, important that the lives and habits of the people comprising the whole area considered should be as nearly similar as possible, not only socially and domestically, but also as regards their surroundings and influences politically.

In all these respects the United States of America possesses the most eminent advantages. It comprises a territory three thousand miles in length by two thousand miles in width. Its area is over three millions and a half of square miles, which is twenty-nine times larger than Great Britain and Ireland, or nearly equal in extent to the whole continent of Europe. It possesses all ranges of mean temperature for the year, from 35° F. to 75° F.; all altitudes, from the sea-level to fifteen thousand feet; all ranges of rainfall, from ten to sixty inches. The conditions of its atmosphere embrace the features of extreme dryness characteristic of far inland plains, of cool moisture from great inland lakes, and the influences of the sea varied by two oceans and numerous ocean currents. Its northeastern border is covered with snow nearly half of the year, and during the same time its southern coast is covered with vegetation of almost tropical luxuriance. It will therefore be seen that such a wide range of geographical and climatic features enables us to readily determine many questions relating to the influence of climate over disease which are difficult and even impossible to solve in those countries possessing a more limited area and climatic range.

In addition to this, the unrivaled facilities of intercommunication possessed by the United States, including the railway, press, post, and telegraph, bring the population nearer together and make the people more nearly a unit in habits and life than has hitherto been attained in any age or country of equal extent.

Unfortunately, however, with all these unsurpassed natural advantages for scientific investigation, the United States at present is placed at great disadvantage as compared with the older, and in fact with all other civilized nations, in the fact that, unlike them, it has no uniform system of registration of vital statistics. Indeed, were it not for the data afforded by the census, it would be impossible to arrive at any conclusions in the field under consideration which could be looked upon as even approximately correct. Fortunately, in the last census—that of 1880—special efforts were put forth to obtain more complete and accurate returns of deaths than had before been furnished, and likewise to make the returns more accurate as regards the causes of death.

In availing myself of the data afforded by the Tenth Census the same course has been followed, with the view of eliminating errors, which I adopted in the study of climatic influences over other diseases.* Thus all States and Territories furnishing a total mortality of less than five thousand have been excluded from the estimates as too small to give trustworthy data.

The total number of deaths in the United States for the year 1880, as recorded by the census returns, was 756,893, and of these 5,386 were returned under the head of Bright's disease. These returns give us an average ratio of 7·11 deaths from Bright's disease in each 1,000 deaths for the whole country. In order to bring out in strong contrast the relative ratios of mortality from Bright's disease in the different States and Territories, I have constructed Table I, which gives the total mortality, the mortality from Bright's disease, and the ratio of the latter to each 1,000 deaths in each State.

* *Treatise on Diabetes.*

TABLE I.

Deaths from Bright's Disease to each 1,000 Deaths, by States, in the United States for 1880.

STATES.	Total deaths.	Deaths from Bright's disease	Ratio to 1,000.
Alabama	17,929	86	4·79
Arkansas	14,812	29	1·95
California	11,530	81	7·02
Connecticut	9,179	132	14·48
Georgia	21,549	36	1·67
Illinois	45,017	213	4·73
Indiana	31,213	108	3·46
Iowa	19,377	67	3·45
Kansas	15,160	38	2·50
Kentucky	23,718	78	3·28
Louisiana	14,514	105	7·23
Maine	9,523	89	9·34
Maryland	16,919	195	11·52
Massachusetts	33,149	431	13·00
Michigan	19,743	100	5·06
Minnesota	9,037	35	3·86
Mississippi	14,583	38	2·60
Missouri	36,615	106	2·89
Nebraska	5,930	10	1·68
New Hampshire	5,584	71	12·70
New Jersey	8,474	242	28·55
New York	88,332	1,779	20·13
North Carolina	21,547	40	1·85
Ohio	42,610	256	6·00
Pennsylvania	63,881	491	7·68
South Carolina	15,728	39	2·47
Tennessee	25,919	39	1·11
Texas	24,735	53	2·14
Vermont	5,024	52	10·33
Virginia	24,681	73	2·95
West Virginia	7,418	33	4·46
Wisconsin	16,011	80	4·99

A glance at Table I discloses the fact that the mortality from Bright's disease in the State of New Jersey exceeds the average for the whole country by a little over four times. New York State comes next in order, exceeding the average nearly three times. Connecticut follows, with a ratio of over double the average, while Massachusetts and New Hampshire follow, almost doubling the average for the country. Whatever be the causative influences, these five adjoining States form a strip of territory, reaching from the 39th to the 45th parallel, which is especially prolific of Bright's disease.

Before it will be possible to assume with reason that the increased fatality from Bright's disease in this region is due to special features of the climate, it must first be ascertained if the States furnishing lower death-rates from the disease than the average differ essentially in their climatic features from those just named. By again referring to Table I it will be seen that the State of Tennessee furnishes a death-rate from Bright's disease which is less by six times than the average for the whole country—viz., 1·11. Georgia follows in order with a ratio of 1·67—about four times less than the average. Nebraska follows with about the same ratio. North Carolina and Arkansas are next in order, their ratios of mortality from the disease being less than the average by about three times and a half. The States of Tennessee, Georgia, North Carolina, and Arkansas form an adjoining tract of territory, extending from the 31st to the 37th

parallel, which lies at directly the opposite point of the compass from the States which furnish the highest death-rate from Bright's disease in the country. Now, in every instance the five States furnishing the lowest ratios of mortality from Bright's disease possess distinct and similar characteristics of climate, the chief features of which are *dryness*, *equability*, and *warmth*. On the other hand, in every instance the five States furnishing the highest death-rate from Bright's disease possess distinct and similar characteristics of climate, the chief features of which are directly the opposite of those of the States furnishing the lowest death-rates from the disease—viz., *moisture*, *coolness*, and *changeability*.

The variation of the death-rate from Bright's disease in each individual State named is so decided a departure from the average for the whole country—200 to 600 per cent.—that ample room is left for errors through other and minor causes, whose influence is not ignored and will be considered later.

It is well known to climatologists, however, that more accurate and trustworthy results are to be reached in estimating the influences of climate over disease by grouping together large areas of territory, including several States, in part or whole, whose chief climatic features are as near similar as possible. By taking each of these grand groups as the unit of calculations, many errors are eliminated from the estimates that must necessarily creep into the calculations when the State is taken as the unit; and, moreover, by so doing, a more limited and purely political division of territory is substituted by a larger and purely climatic division.

In order to further facilitate the study of the climatic features of Bright's disease in the United States by grand groups,* I have constructed Table II, which gives the ratio of deaths from Bright's disease, the mean annual temperature, the annual rainfall, the elevation, and the population of each grand group.

Table II.

Deaths from Bright's Disease in each 1,000 Deaths in the United States for 1880, in Grand Groups, showing Climatic Features and Population of each Group.

REGION.	Ratio to 1,000.	Mean temperature F.	Mean rainfall in inches.	Elevation, in feet.	Population.
1. North Atlantic coast region	17·38	40–50°	40–50	100– 500	2,616,870
2. Middle Atlantic coast region	19·73	45–60	45–55	Below 100	4,376,135
3. South Atlantic coast region	2·59	60–65	50–60	" 100	875,086
4. Gulf coast region	9·41	70–75	55	" 100	1,056,034
5. Northeastern hills and plateaus	11·20	35–45	35–45	500– 2,500	1,669,229
6. Central Appalachian region	8·23	40–45	35–40	Above 500	2,344,089
7. Northern lake region	7·17	45–50	30–40	200– 300	3,049,402
8. The interior plateau region	8·32	45–50	40–45	100– 200	5,714,683
9. The Ohio River belt	5·83	45–55	45–50	300– 1,000	2,440,339
10. Southern Central Appalachian region	2·63	45–55	45–50	1,000– 2,000	2,697,958
11. Southern interior plateau	2·99	65–70	50–60	B'low1,000	3,625,545
12. South Mississippi river belt	3·14	60–65	50–55	100– 300	710,250
13. North Mississippi river belt	3·73	40–50	30–50	Above 500	1,990,917
14. Southwest central region	1·97	60–70	25–50	100– 500	2,932,676
15. Central region (plains, etc.)	3·70	50–60	40–45	500– 1,500	4,403,662
16. Prairie region	3·59	50–55	25–40	Ab'vc1,000	5,721,836
17. The Missouri river belt	2·80	40–55	20–40	500– 1,000	835,694
18. The Northwestern region	5·21	40–50	30–40	Ab'vc1,000	1,123,419
19. Pacific coast region	8·72	45–65	20–60	100– 2,000	715,781
20. Region of Western Plains	3·92	45–65	10–20	1,500– 5,000	324,268
21. The Cordilleran region	3·04	50–60	10–20	1,000–10,000	931,910

* The grouping herewith adopted is that proposed by Mr. Gannett, the geographer of the Census.

Upon examination of Table II, it will be seen that Bright's disease attains its highest mortality in the Middle Atlantic coast region—19·73 in 1,000—or considerably over two and a half times more than the average for the whole country. The North Atlantic coast region comes next in order, the ratio being 17·38 in 1,000. The northeastern hills and plateaus furnish the next highest ratio—11·20 in 1,000 deaths. The average for the three regions just named is 16·15 in 1,000—or nearly two and a half times higher than the average for the whole country. If we examine the climatic features of this tract as a whole, it must be conceded to be the coldest, the most exposed, the most changeable, as well as among the most humid in the United States. The Middle Atlantic coast region, which furnishes the highest ratio of mortality from Bright's disease (19·73) of the grand groups, is by no means the coldest region in the country, although the northern half thereof is very cold, the mean temperature range for the year being only 45° to 50° F. The climate is eminently a moist one, for, in addition to the direct influence of the sea, the surface of the country is low and sandy, and along parts of the coast—notably that of New Jersey—there are sandy reefs, shoreward from which are lagoons succeeded by extensive areas of swamp. Further inland the country is low, nowhere rising to exceed one hundred feet above the sea. In addition to this, the mean annual rainfall is high—forty-five to sixty inches. The changes of temperature are frequent, often sudden, and sometimes extreme. On the whole, however, so far as the temperature is concerned, the mean range is from 10° to 15° F. higher than in the regions of the North Atlantic coast and the northeastern hills and plateaus, where the death-rate from the disease is somewhat lower. It may therefore be properly asked, What determines the greater mortality from Bright's disease in the Middle Atlantic coast region over that in the North Atlantic coast and northeastern hills and plateaus, since the climate in the two latter regions possesses the chief features which we have thus far found prolific of the disease, to a degree at least as marked as in the Middle Atlantic coast region?

In attempting a solution of this question it should first be remembered that the Middle Atlantic coast region contains most of the larger and older cities of the country, and consequently much of the national wealth. Now, it is well known that wealth encourages a course of living that especially predisposes to Bright's disease. Indeed, no fact has become more widely recognized than that chronic Bright's disease (interstitial nephritis) is largely the outgrowth of luxurious living—the over-taxation of the kidneys in eliminating the waste products of highly nitrogenous foods. Moreover, this form of Bright's disease is uncommon before the age of forty years; indeed, it is most frequent after fifty. The Middle Atlantic coast region, containing so large a proportion of the older and wealthier population of the country, must therefore necessarily have a higher ratio of mortality from the interstitial form of Bright's disease. Besides this, nearly one half of the population of the Middle Atlantic coast region is urban, and that form of renal disease known as amyloid degeneration of the kidney (commonly returned under the head of Bright's disease on ac-

count of its accompanying dropsy and highly albuminous urine) must be more frequent there since it is so largely the outgrowth of syphilis, a disease always more frequent in large cities. Lastly, old age, scarlatina, and pneumonia are factors which stand in close causative relationship to Bright's disease as a whole, and these factors are possessed by the region in question to a degree perhaps exceeding any region in the United States. If, therefore, we consider the ætiology of Bright's disease apart from climatic influences, we find that the Middle Atlantic coast region possesses the general elements of cause of the disease to a degree exceeding any other region of the country. Add to this the influences of climate whose leading features tend strongly toward high mortality from the disease, and the solution of the question no longer seems a difficult problem.

If now we direct attention to the North Atlantic coast region we find that the death-rate from Bright's disease is very high—17·38 in 1,000. The climate of this region is the most trying in many respects of the whole country. The mean temperature is 45° F., and the mean rainfall is about forty-five inches. This region is exposed to the damp chilling winds from the North Atlantic Ocean. In short, the climate is eminently a cold, moist, and changeable one. The general causes of Bright's disease, apart from climatic influences, are not so marked as in the Middle Atlantic coast region, and therefore the high mortality of the disease in this region is probably more purely due to the special features of climate named.

The next highest death-rate from Bright's disease is reached in the Northeastern hills and plateaus—viz., 11·20 in 1,000. Although possessing the third highest ratio of mortality from the disease of the grand groups, the ratio is considerably lower than in either of the two last grand groups considered. The climate of the Northeastern hills and plateaus is exceedingly cold, the mean range of temperature being but 40° F. This region is also an exposed one owing to its high altitude. It lacks, however, the character of humidity to the degree possessed by the two regions just considered. It is removed from the direct influence of the sea and has a mean rainfall of only about forty inches. There can be little doubt that the lessened mortality in this region from Bright's disease as compared with the two regions last considered is largely due to the comparative dryness of the atmosphere, while a high mortality, as compared with the whole country, is still maintained by the cold and exposed position of this region.

If now we turn to the Southwest central region, we find the rate of death from Bright's disease to be the lowest of all the grand groups in the country—viz., 1·97 in 1,000. The climate in this region is eminently a *dry*, *warm*, and *equable* one. With a mean annual temperature of from 60° to 70° F., and a mean rainfall of thirty-five to forty inches, its chief climatic features are directly opposite to those of the grand groups which furnish the highest death-rates from Bright's disease in the country.

The South Atlantic coast region furnishes the next lowest ratio of mortality from Bright's disease of the grand groups—viz., 2·59 in 1,000. The mean temperature of this region is 60° to 65° F., and the mean rainfall is fifty-five inches. The climate of this region is a warm though rather moist one. It will be remembered that the South Atlantic coast is washed by the Gulf Stream before the latter has had time to mingle to any extent with the cool waters of the Atlantic Ocean, and therefore the east winds are warm and balmy. In addition, this region is sheltered from the north and west winds by the Appalachian range of mountains, and therefore the equability of its temperature is most marked. We learn from these facts that equable warmth tends to induce a low death-rate from Bright's disease, even though the climate is a moist one, and this statement is confirmed by the fact that the Bahama Islands, which are off the South Atlantic coast region, possess a climate that is esteemed for its favorable influence over Bright's disease the world over.

The Southern Central Appalachian region furnishes the next lowest death-rate from Bright's disease of the grand groups—viz., 2·63 per 1,000. This region may be practically considered a continuation of the South Atlantic coast region to the westward. It differs from the latter chiefly in possessing a drier atmosphere at the expense of one slightly cooler, depending upon its higher altitude and greater distance from the sea.

The three grand groups just described, if considered as a whole, form a large tract of practically inland territory of crescent shape, the curve of which corresponds with that of the north line of the Gulf coast. It is removed from the latter sufficiently far to escape the moisture of the sea, and yet it is situated sufficiently near to receive the tempering influences of its warmth and equability. On the north and east it is protected by the base of the great Appalachian range of mountains. The conditions are therefore such, on the whole, as to produce warmth, equability, and dryness of climate to a degree nowhere else attained in any tract of equal extent in the United States. We must therefore conclude that—whether we take the State, the grand group, or a group of grand groups, as the unit of calculations—that which combines the highest range of temperature with the greatest equability and dryness of the atmosphere furnishes the lowest death-rate from Bright's disease, and, *vice versa*, that which combines the lowest temperature range with the greatest degree of atmospheric moisture and changeability furnishes the highest death-rate from the disease. It is true that a few *apparent* contradictions to these rules may be found, but, upon careful consideration, most if not all of these are readily harmonized. Thus it will be observed by glancing at Table II that the Gulf and Pacific coast regions furnish death-rates from Bright's disease considerably above the average for the whole country. At first thought this might perhaps seem surprising, considering the climatic features of these regions and the further fact that it has become the fashion in the United States to send those afflicted with Bright's disease to one or the other of these localities for curative purposes. Upon reflection, however, the fact explains itself, for many of those in practice can attest that numbers of their patients do not return, or, if they do, they leave the records of their deaths to swell the death-rates of the disease in the places under consideration.

With regard to altitude, it may be stated that statistics do not indicate that it very materially influences the death-rate from Bright's disease further than its influence over temperature is concerned. In the northeastern hills and plateaus, where the elevation above the sea averages perhaps 2,000 feet, the mortality from Bright's disease reaches the third highest ratio of the grand groups of the country. On the other hand, in the Southern Central Appalachian region, where the altitude is even higher, the mortality from the disease sinks to the third lowest of the grand groups of the country.

Again, the Middle Atlantic coast region furnishes the highest ratio of mortality from the disease of all the grand groups in the country, and this region possesses a mean altitude of less than 100 feet above the sea; while, on the other hand, in the Cordilleran region the altitude altogether exceeds that of any other grand group in the country, yet we find the death-rate from Bright's disease in this region to be only 3·04 in 1,000—considerably less than half the average for the whole country.

In view of these observations, it must be concluded that the influence of altitude over Bright's disease in general is very slight as compared with those features of climate already considered. In this connection the fact should not be overlooked that in those forms of Bright's disease which are complicated by advanced cardiac disease, notably the late stages of interstitial nephritis, high altitudes are *distinctly dangerous.* In such cases the heart failure is hastened by the high altitude, which in turn is very prone to bring on fatal uræmia.

A review of these investigations substantiates the following conclusions:

1. That the chief features of climate in the United States which most strongly tend to increase the death-rate from Bright's disease are cold, moisture, and changeability of temperature.

2. That the elements of climate which tend in the greatest degree to decrease the death-rate from Bright's disease are warmth, dryness, and equability.

3. That cold most markedly increases the mortality from Bright's disease when associated with moisture, a comparatively low temperature being well borne if the atmosphere is a dry one.

4. That a comparatively high degree of humidity of the atmosphere does not markedly increase the mortality from Bright's disease if accompanied by warmth and equability.

5. That the most unfavorable residence localities for patients afflicted with Bright's disease in the United States are comprised within the Atlantic coast region and Northeastern hills, which include the States of New Jersey, New York, Connecticut, Massachusetts, New Hampshire, and Vermont.

6. That the most favorable residence localities are chiefly comprised within the Southern interior, and especially include the States of Tennessee, Georgia, North Carolina, Arkansas, and Texas.

7. Finally, a practical lesson may be learned from these investigations as follows: That, since climate so decidedly influences the mortality from Bright's disease, those who are afflicted with the disease or possess strong hereditary or other tendencies thereto should wear such garments as most directly tend to neutralize the evil influences of climate over the disease—viz., *those combining the minimum power of radiation of body heat with the highest hygroscopic properties; and since wool possesses these qualities to a degree unapproached by any other textile, all-wool garments should be worn next the skin throughout the year.*

TOTAL VAGINAL EXTIRPATION OF THE UTERUS

RANDOM NOTES.

By D. TOD GILLIAM, M. D.,
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, STARLING MEDICAL COLLEGE, COLUMBUS, OHIO.

As between supravaginal amputation and total extirpation of the cancerous uterus, about which so much is being said and written nowadays, I shall draw no invidious line. Doubtless each has its sphere of utility, and the time will come when the indications for one or the other will be more clearly defined. The relative mortality of the two operations is about two to one in favor of the less radical operation. While under expert hands the death-rate of vaginal hysterectomy has been reduced to five per cent., yet in the aggregate of all operations it is probably not less than fifteen to twenty per cent. Supravaginal amputation in like manner gives a death-rate of about seven per cent., whereas in the hands of a favored few it does not exceed over two to three per cent. Recurrences are a little less frequent and are longer delayed in vaginal hysterectomy, giving an average exemption of about thirty-three per cent. after two years to some German operators. As to the indications for one or the other, the high amputation has a much broader range than total extirpation. The latter is not to be thought of in cases where the mobility of the uterus is much restricted. It is a good rule, and one generally observed, not to attempt total extirpation in any case where the cervix can not be drawn down to the vulva; also in very large uteri, or where there is a complication with fibroid or other massive growth, or where there are strong adhesions, or the vaginal canal is unusually narrow and deep, or when, as occasionally happens, the intestines are adherent to the uterus, or when the broad ligaments are obviously involved in the disease as manifested by thickening, induration, and absence of elasticity. It is safer in every case before operating to not only sound the uterus and test its mobility, but also to anæsthetize the patient, and, drawing the uterus down, make a thorough rectal exploration. In case of intestinal adhesions, if they should prove very firm, the operation should be abandoned, otherwise they may be better dealt with after one of the ligaments is severed and the uterus brought to light, provided always the adhesions are confined to the uterus proper.

In case the cervix is gone and the cavity of the uterus so diseased as to be very friable, traction can be made by a diverging double tenaculum forceps introduced into the cavity and expanded, using very moderate force until the

outer surface of the uterus has been cleared sufficiently to admit of a good hold by the volsella.

In a recent case the high operation had been previously performed and a dense, cicatricial tissue formed between the bladder and the uterus; the cavity was cancerous to the fundus. Even the tenaculum forceps plowed through it when much traction was used. I was exceedingly uneasy about this case, fearing that the scar tissue would divert me from my course into the bladder or uterus, but by graduating the traction just so as to steady the uterus, I carefully worked my way for a short distance through the scar tissue, keeping my bearings by means of a sound in the bladder, and soon had the satisfaction of striking the loose cellular tissue, when the volsella was applied, and from then on I had plain sailing.

I prepare my patient for the operation by having the bowels cleared and a vaginal injection of four or five gallons of warm (not hot) water. This not only cleanses the parts thoroughly, but produces a relaxation that facilitates the subsequent steps of the operation. The bladder being emptied, the patient is placed on the table in the lithotomy position. Before the speculum is introduced the vagina is thoroughly mopped out with absorbent cotton saturated with a 1-to-5,000 solution of mercuric chloride. The Sims speculum and two retractors—one on either side—being introduced, the cervix is seized with tenacula or volsellæ or transfixed by strong cords and drawn down. Now with the knife a rather free incision is made at the cervico-vaginal junction into the submucous connective tissue. This cut must completely surround the cervix, but should be extended on either side to afford room for clamping the broad ligaments. Now with the finger, scalpel handle, and scissors separate the bladder from the uterus, keeping close to the latter and doing as little cutting as possible. Having arrived at the peritonæum, which is evidenced by a lack of resistance, Douglas's *cul-de-sac* is exposed in like manner, and opened by a stroke of the knife or snipped by the scissors. Introducing a finger over the broad ligament into the vesico-uterine space, the peritonæum is opened on it.

I have usually disregarded this rule and pushed my finger through from below, as it is rather an advantage than otherwise to have the peritonæum stripped from the anterior surface of the uterus as far as it will go. The openings are now enlarged by pressure with the fingers until the uterus is cleared from side to side and the broad ligaments made freely accessible. One or two sponges properly prepared and with cords attached are now introduced into the peritoneal cavity to absorb the blood and to keep the bowels and other parts out of harm's way. During all this time bleeding points are taken up by pressure forceps as they are exposed, sometimes as many as a dozen or more being needed, at others none.

The finger, or, if tense and unyielding, a steel hook, is now placed over the left broad ligament under guidance of the finger, and the latter drawn down. Following Reamy's suggestion, I habitually use the obstetric crotchet-hook for this purpose, and it answers admirably. The broad-ligament forceps is now passed up alongside and near to the uterus and slid outward on the ligament, bearing in mind the proximity of the ureter and not attempting to take too big a bite, lest this be included. If the uterus is well drawn down, there is much less risk of catching up the ureters than if it be left near its normal situation. With a finger at the distal end of the forceps blade in the peritoneal cavity the forceps is closed so as to take in the entire depth of the ligament and not include anything else. Should the ligament be too much crumpled or rounded by reason of traction on the hook, this must be relaxed while the forceps is being adjusted. I prefer a forceps with a central longitudinal groove, like the Wathens, as the tissues bulging into the groove gives a firmer hold and there is less danger of slipping. It is better also that the blades when closed should not touch their entire length, but that one should be able to see light through that part nearest the handle, as the base of the broad ligament is a little thicker than the upper part, and equalized pressure is better secured thereby. Some time since I got a set of forceps from Tiemann, one of which I considered defective by reason of this non-parallelism of the blades, but in using them I found it the most perfect instrument I had. Having secured the ligament, sever the uterus by scissors, being careful not to cut too close to the forceps. The uterus may now be drawn down and the other forceps adjusted under the eye. The uterus is now cut away, and, after looking carefully for bleeding vessels, the vagina is again mopped out with the bichloride solution, the sponges withdrawn, the vagina packed loosely with iodoform gauze, and the patient put to bed. I do not sew up the peritonæum, for the reason that if no obstacle exists it quickly falls together and heals. On the other hand, should antagonistic conditions prevail, the demands for free drainage will be better subserved by leaving a free opening. The tampon is left in from two to four days, owing to the degree of foulness which develops, or, should the patient's condition suggest infection, it is immediately withdrawn, and, after gentle swabbing with the bichloride, a fresh one introduced. All except the broad-ligament forceps are removed at the expiration of twenty-four hours. The latter are left on forty-eight hours. It is better not to disturb the tampon for twenty-four hours after removal of the forceps, for the reason that, in separating the blades to withdraw them, an opening may be made into the peritoneal cavity through which germs or extraneous matter may gain entrance. I have made it a rule to open the bowels on the second day, whereby intestinal adhesions may be averted. There are no hard rules to follow, however, as this very day I have violated one of the injunctions laid down above. It is now the second day since operating, and consequently time to remove the last forceps. I found her very foul, and consequently swabbed her out and introduced a fresh tampon coincidently with the withdrawal of the forceps. This case taught me another lesson: The first steps of the operation were almost bloodless. Just as I was in the act of severing the last broad ligament the forceps slipped, and the field was deluged in blood. This being secured, a great many vessels from the hidden recesses of the retracted tissues began to spout, and when, after a half hour's hard work, the hæmorrhage was stanched, the vagina was literally packed with pressure forceps.

THE

NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by D. Appleton & Co.

Edited by Frank P. Foster, M. D.

NEW YORK, SATURDAY, OCTOBER 4, 1890.

THE MEDICAL SERVICE OF THE NATIONAL GUARD OF THE STATE OF NEW YORK.

The *Annual Report of the Adjutant-General* for the year 1889, transmitted to the Legislature on February 20, 1890, furnishes noteworthy evidence of the continued efficiency of the medical corps of the National Guard. At the date of the report the force comprised fourteen regiments, one battalion, and forty-five separate companies of infantry, five batteries of artillery, one troop of cavalry, and two signal corps, amounting on the 30th of September, 1889, to 14,222 officers and men, and being divided into four brigades. The medical corps includes the surgeon-general (Dr. Joseph D. Bryant, of New York), four brigade surgeons (Dr. Robert V. McKim, of New York; Dr. George R. Fowler, of Brooklyn; Dr. Herman Bendell, of Albany; and Dr. Roswell Park, of Buffalo), and a surgeon and assistant surgeon for each regiment. In his own report Surgeon-General Bryant speaks in high praise of the medical officers serving under him and of the sanitary condition of the State Camp, but he deprecates the lack of punctuality and fullness characterizing the reports of some of the regimental medical officers. As an example of what they would do well to emulate, he gives the report made to him by Surgeon E. T. T. Marsh, of the Seventy-first Regiment, within three weeks of the time when that regiment began its week's encampment. Dr. Marsh, who acted as post surgeon during his regiment's encampment, furnished certain recommendations to the commanding officer of his regiment at the ontset, and at the same time some hits of advice to the men—all intended to further the preservation of the men's health while in camp. For the most part the advice given by Dr. Marsh was such as every experienced medical officer would undoubtedly urge, and none of it was what such an officer would regret.

In concluding his report, Dr. Marsh makes certain recommendations with regard to the management of the camp—among them, that the number of bath-houses be at least doubled; that the main street he put in a condition, by means of concrete or brick, to enable it to withstand the constant sweeping to which it is necessarily subjected in rainy weather, which now leads to the formation of hollows and consequent puddles; that the high underbrush and lower limbs of the trees on the edge of the bluff and the borders of the camp be cut away so as to allow of a freer circulation of air in and about the camp; and that the members of the ambulance corps be allowed to wear the brassard at all times when they are on duty, inasmuch as some of them were fired on during a sham battle, and one had his face burned with gunpowder. The surgeon-general does not seem to agree with Dr. Marsh as to the utility of cutting away the underbrush and low branches of trees; indeed, he affirms anew that there should be larger and taller trees, and more of them, on the top and the incline of the bluff, not only to afford shade during the heat of the day, but also to aid in warding off any malarial influences that may emanate from the neighboring marshy ground.

During the past few years a point has been made in the National Guard of instructing details of men in the elements of the art of rendering prompt and well-directed aid to the wounded and disabled. This is one of many manifestations of Surgeon-General Bryant's devotion to the good of the service. Of its great value examples have been abundant, but it is none the less gratifying to see that Colonel Loder, of the Fifth United States Artillery, the officer deputed to report upon the New York State Camp of Instruction at Peekskill, makes particular mention of it and gives Dr. Bryant special credit for its introduction. "The idea," says Colonel Loder, "contemplates the extending of aid to the unfortunate citizen who may suffer from the effects of physical violence received in the daily walks of life, as well as to the National Guardsman who may fall while on his special duty. Trained National Guardsmen may thus aid the citizen in other ways than as a 'man under arms.'"

Surgeon-General Bryant properly protests against the practice of issuing disused uniforms to recruits. The use of second-hand uniforms, he remarks, is never ennobling, especially when they are soiled and out of repair—perhaps the cast-off garments of those who have been dropped for dereliction of duty. He calls attention again to the necessity of remedying the prolonged and profound saturation of the soil beneath and around the present kitchen in the camp. Although no case of disease traceable to any such agency occurred during the year, it may well play havoc in the future if it is not dealt with energetically. All his recommendations seem to us such as ought to be carried out.

AN EPIDEMIC OF GHOSTS.

Those who are interested in the manias of the middle ages will be somewhat amazed to hear that in the last decade of the nineteenth century a nervous epidemic of an hallucinatory kind should have made itself prevalent among such very matter-of-fact people as the citizens of Berlin. Our energetic and persevering friends in the bacteriological laboratory have not yet found a microbe to account for the contagion of bodily fear, that uncomfortable sensation about the epigastrium which attacks individuals first and rapidly extends itself to large numbers of people, resembling in its onset the work of the most active microbe. We must, therefore, assume the existence of a mental contagion to explain the occurrence of the extraordinary psychical disturbances of which we read in history and of which to-day we witness an example.

Berlin was a few weeks ago the scene of a most extraordinary demonstration of the contagious effect of fear. In one of the public schools, a silly young girl, frightened by the flapping of a window curtain, imagined that she had seen a ghost, and

communicated her dread to the rest of the scholars until something like a panic ensued. Not only did the scholars in this one school begin to see ghosts, but rapidly ghost-seeing became prevalent in other schools, until now the moral contagion has involved many of the schools of the suburbs, as well as those of the capital itself. The force of example, acting upon minds weakened by overwork, operates with a morbid activity, and cases of hysterical outbreaks in factories, convents, and schools have very frequently been reported. The educational forcing system, what Charles Dickens would call the production of mental green peas at Christmas and intellectual asparagus all the year round, of which our German friends are so fond, may play an important rôle, to borrow one of their expressions, in the ætiology of these contagious moral epidemics. There is not much change in the world after all. The intense religious fervor of the middle ages is replaced by the witchcraft craze and the *convulsionnaire* movement of the last century, and now these give place in our time to religious revivals of the wildly emotional type, the howling and writhing of the camp meeting, the strange tongues of Irvingism, and the dancing parade of the salvation soldiers. All such movements have a strong family resemblance the one to the other, and their grotesqueness is proportionate to the degree of education prevalent at the period in which they occur.

With the ghost mania it is reported that the Berlin authorities have adopted vigorous measures, but what form these have taken we have not yet been informed. Perhaps the paternal government of Germany will employ the treatment recommended by Paracelsus for the dancers of his time, namely, total immersion of each patient in cold water. The American spank-cure, as described by a contemporary, might also prove serviceable. The prompt application of the old-fashioned calorifacient slipper to the next child announcing itself as a seer of ghosts might aid in putting an end to what appears to be really a very serious mania.

MINOR PARAGRAPHS.

A TARDY ACKNOWLEDGMENT.

Several years ago Dr. Lewis A. Stimson presented before the New York Surgical Society an account of certain elaborate experiments that he had performed for the purpose of testing the efficiency of germicides in the form of spray as destroyers of atmospheric germs. This was at a time when everybody who believed in antisepsis at all trusted implicitly to the spray. Dr. Stimson's experiments convinced him that the common belief was fallacious, and he stated this conviction without reserve, a procedure that showed his entire confidence in the methods he had employed in the investigation. His paper was published in a Philadelphia journal, and he soon found himself the subject of English criticism of considerable severity, not unmingled with scorn. But in Germany his experiments were repeated and corroborated, and *fort mit dem Spray!* became the cry. The spray fell into general disuse, but we are not aware that its promoter, Sir Joseph Lister, ever formally acknowledged that he had erred in advocating its employment until he did so in his address at the recent Berlin meeting of the International Medical Congress.

MÜLLER'S SYMPTOM IN AORTIC INSUFFICIENCY.

According to the *Gazette hebdomadaire de médecine et de chirurgie*, Dr. Matthieu, in a recent Paris thesis, states his belief that the symptom is occasionally presented under the triad of visible capillary pulse, carotid beating, and pulsation of the uvula and soft palate. The second and third of these peculiarities are most often associated, and constitute the visible pulse of the isthmus of the pharynx. Exceptionally the pharynx is agitated by the pulsations to the exclusion of the tonsils and pillars of the fances. The appearance of the symptom depends upon: 1. A very energetic cardiac impulse. 2. A considerable volume of the systolic wave. 3. The loss of elasticity of the peripheral arteries, either by spasm or by degeneration. The symptom was only encountered in patients affected with simple or complicated aortic insufficiency, and only in about fifty per cent. of those examined. The symptom may be useful in making a diagnosis when a pulmonary affection renders auscultation of the heart difficult, or when it is impossible to distinguish between the bruit of aortic insufficiency and certain extracardiac murmurs of pulmonary origin or pericardial friction sounds, or when a systolic murmur at the base may be attributed to aortic stenosis or aortitis deformans.

POISONS FOR THE BACILLUS TUBERCULOSIS.

Professor Koch says, according to the *British Medical Journal*, that he has tested a very great number of substances to ascertain the influence that they exerted on the tubercle bacilli in pure cultures. The following substances, even in small quantities, hindered the growth: A number of ethereal oils; of the aromatic compounds, β-naphthylamine, paratolnidine, xylidine; the aniline dyes, fuchsine, gentian violet, methyl blue, quinoline yellow, aniline yellow, auramine; mercury in vapor, and silver and gold compounds. A compound of cyanogen and gold, even in a dilution of one to two millions, checked the growth of the bacillus. These substances had no effect on tuberculous animals. Light was as potent as chemicals, sunlight killing a layer of tubercle bacilli in a few minutes or hours, according to the thickness of the layer. Ordinary daylight will exercise the same effect in from five to seven days.

CAMPHORIC ACID AS AN ANTHIDROTIC.

Lyon médical gives an abstract of an article by M. Leu, published in the *Bulletin médical*, setting forth the results of certain trials of camphoric acid, given internally, to control the profuse sweats of phthisical patients. It was usually given at bedtime, in doses of thirty grains; sometimes that dose was given in the afternoon and a slightly larger one in the evening. It often happened that the anthidrotic effect was not shown until the third day, but generally the effect of a single dose lasted for several days. Out of sixty-five trials on thirteen patients, sixty per cent. were completely successful, and in twenty-two per cent. the sweating was moderated. The drug is soluble with difficulty in water, but dissolves more readily in alcohol. Its taste is said not to be disagreeable. Some trials of an alcoholic solution in the form of a lotion, for localized sweating, proved satisfactory.

MR. HUTCHINSON ON CIRCUMCISION.

In the *Archives of Surgery* Mr. Jonathan Hutchinson sums up his experience in regard to the sanitary advantages of the rite of circumcision. After premising that it is not needful to go on a search for any recondite motive for the origin of the practice, he says: "No one who has seen the superior cleanli-

ness of a Hebrew penis can have avoided a very strong impression in favor of the removal of the foreskin. If not removed it constitutes a harbor for filth, and is, in many persons, a constant source of irritation. It conduces to masturbation and adds to the difficulties of sexual continence. It increases the risk of syphilis in early life and of cancer in the aged. I have never seen cancer of the penis in a Jew, and chancres are rare."

A PROJECT TO INCREASE THE FISH SUPPLY OF NEW YORK STATE.

A number of gentlemen living in Rochester have undertaken to procure funds for restocking Lake Ontario with whitefish, and legislation to prevent the extermination of the new stock. They have the support of the local newspapers and the approval of their member of the State Fish Commission. The undertaking is most commendable, and we have no doubt that the physicians of the State will gladly aid in its accomplishment by whatever influence they may have with legislators and with persons who may be looked to for contributions.

MEDICAL DRAWINGS.

Dr. Henry Macdonald, whose change of address we record elsewhere in this issue, informs us of his willingness to devote a portion of his time to making anatomical and other drawings for members of the profession. We have published many engravings from Dr. Macdonald's drawings, and others have appeared in various medical books. His work is, indeed, so well known as to stand in no need of commendation. We will simply express the hope, therefore, that his otherwise unoccupied time may be sufficient to enable him to do all the drawing that he is called on to do.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending September 30, 1890:

DISEASES.	Week ending Sept. 23		Week ending Sept. 30.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	39	13	61	11
Scarlet fever	17	7	27	3
Cerebro-spinal meningitis	1	0	3	3
Measles	45	6	25	2
Diphtheria	42	17	54	14
Small-pox	0	0	1	0
Whooping-cough	0	0	2	0

Mount Sinai Hospital.—There is a vacancy in the eye department of the dispensary. Applicants, who must be proficient in the German language, may address Mr. S. L. Fatman, chairman of the dispensary committee, at the hospital, Lexington Avenue and Sixty-sixth Street.

Reed & Carnrick's Foods.—The recent destruction of one of Messrs. Reed & Carnrick's factories by fire will not, we learn from the *Dietetic Gazette*, prevent the firm from filling orders pending the completion of the new building, as their stock on hand in New York is large.

The State Board of Medical Examiners of New Jersey will meet in the Senate Chambers at the Capitol in Trenton, on Thursday, October 9th, at nine o'clock in the morning, for the purpose of examining candidates presenting themselves for a license to practice medicine in the State. Under the present medical law of the State every person desiring to practice medicine or surgery, in any of its branches or in any way, who was not legally registered previously to July 4, 1890, must first obtain a license from the board. Any further information will be furnished by the secretary, Dr William Perry Watson, of Jersey City.

The American Rhinological Association will hold its eighth annual meeting in Louisville on Monday, Tuesday, and Wednesday, the 6th, 7th, and 8th inst., under the presidency of Dr. Arthur G. Hobbs, of Atlanta, Ga. The programme announces the president's address and papers or remarks in discussions by Dr. A. B. Thrasher, of Cincinnati; Dr. T. H. Stucky, of Louisville; Dr. E. R. Lewis, of Indianapolis; Dr. L. B. Gillette, of Omaha; Dr. J. G. Carpenter, of Stanford, Ky.; Dr. John North, of Toledo, O.; Dr. C. T. McGahan, of Chattanooga; Dr. C. H. von Klein, of Dayton; Dr. E. C. Painter, of Pittsburgh; Dr. J. H. Coulter, of Peoria; Dr. Emmett Walsh, of Grand Rapids; Dr. A. De Vilbiss, of Toledo; Dr. R. S. Knode, of Omaha; and Dr. T. F. Rumbold, of San Francisco.

The Woman's Medical College of the New York Infirmary.—Dr. George Thomas Jackson has been appointed professor of dermatology in this institution.

The New York Academy of Medicine.—At the next meeting of the Section in Pædiatrics, on Thursday evening, October 9th, Dr. W. L. Stowell will present a Study of One Hundred Cases of Pneumonia in Children. The meeting will be held in the Academy's new building in West Forty-third Street.

The Tri-State Medical Association of Alabama, Georgia, and Tennessee will hold its next meeting in Chattanooga on Tuesday, the 14th inst., under the presidency of Dr. J. B. Cowan.

The Paris Pasteur Institute.—According to the *British Medical Journal*, Professor Metschnikoff, of Odessa, the distinguished Russian bacteriologist, has been appointed head of the Pasteur Institute in Paris, under the general direction of M. Pasteur.

Changes of Address.—Dr. F. Irving Disbrow, to No. 139 West One Hundred and Fourth Street; Dr. Henry Macdonald and Dr. Belle Macdonald, to No. 251 West Fifty-second Street.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 14 to September 27, 1890:*

By direction of the Acting Secretary of War, the following changes in the stations of officers of the medical department are ordered: Spencer, William G., Captain and Assistant Surgeon, will, upon the abandonment of Fort Bridger, Wyoming (his present station), report in person to the commanding officer of Omaha, Nebraska, for duty at that station, relieving Bradley, Alfred E., First Lieutenant and Assistant Surgeon. Lieutenant Bradley, on being relieved by Captain Spencer, will report in person to the commanding general, Department of the Platte, for duty as attending surgeon at the headquarters of that department. Par. 16, S. O. 214, A. G. O., Washington, D. C., September 12, 1890.

By direction of the Acting Secretary of War, the leave of absence granted Suter, William N., First Lieutenant and Assistant Surgeon, in Special Orders No. 149, June 26, 1890, from this office, is extended fourteen days. Par. 6, S. O. 214, A. G. O., Washington, D. C., September 12, 1890.

By direction of the Acting Secretary of War, the leave of absence for seven days heretofore granted McElderry, Henry, Major and Surgeon, by the Superintendent of the U. S. Military Academy, is extended to November 10, 1890, on account of sickness. Par. 5, S. O. 214, A. G. O., Washington, D. C., September 12, 1890.

By direction of the Acting Secretary of War, Cochran, John J., Captain and Assistant Surgeon, now on duty at Fort Adams, Rhode Island, will proceed to Mount Vernon Barracks, Alabama, and report in person to the commanding officer of that post for temporary duty, and on completion of the duty contemplated, he will return to his proper station. Par. 2, S. O. 214, A. G. O., Washington, D. C., September 12, 1890.

By direction of the Acting Secretary of War, leave of absence for three months, commencing about October 1, 1890, is granted Ives, Frank J., Captain and Assistant Surgeon, provided one of the Acting Assistant Surgeons serving in the Department of the Missouri can be assigned to duty in his stead, at Fort Sill, Oklahoma Territory, during that time. Par. 26, S. O. 213, A. G. O., Washington, D. C., September 11, 1890.

KIMBALL, J. P., Major and Surgeon, is, in view of the early abandonment of Fort Elliot, Texas, to which post he is at present assigned for station, relieved from duty at that post, and will, upon the expiration of his present sick leave of absence, proceed to Fort Supply, Indian Territory, and report to the commanding officer for duty. Par. 2, S. O. 132, Department of the Missouri, September 24, 1890.

Under the provisions of General Orders No. 43, c. s., Headquarters of the Army, Adjutant-General's Office, the post of Little Rock Barracks, Arkansas, will be abandoned, to take effect not later than October 1, 1890.

BROWN, PAUL R., Captain and Assistant Surgeon, will accompany Company E to Fort Supply, Indian Territory, and there take station until further orders. G. O. 15, Headquarters Department of the Missouri, St. Louis, Mo., August 11, 1890.

EWING, C. B., Captain and Assistant Surgeon, is granted leave of absence for one month, to take effect the 1st proximo. Par. 5, S. O. 131, Department of the Missouri, September 22, 1890.

APPEL, AARON H., Captain and Assistant Surgeon. The leave of absence for seven days granted by the commanding officer, Fort D. A. Russell, Wyoming, is extended twenty-three days. Par. 3, S. O. 70, Department of the Platte, September 17, 1890.

MIDDLETON, JOHNSON V. D., Major and Surgeon, is relieved from duty at David's Island, N. Y., and will report in person to the commanding officer, Fort Columbus, New York city, for duty at that station, relieving Major Joseph R. Gibson, Surgeon, and reporting by letter to the commanding general, Division of the Atlantic. Par. 1, S. O. 219, A. G. O., Washington, September 18, 1890.

GIBSON, Major, on being relieved by Major Middleton, will report in person to the commanding officer, David's Island, N. Y., for duty at that station, and by letter to the superintendent of the recruiting service. Par. 1, S. O. 219, A. G. O., Washington, September 18, 1890.

Society Meetings for the Coming Week:

MONDAY, *October 6th:* American Rhinological Association (Louisville—first day); New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society (private); Brooklyn Anatomical and Surgical Society (private); Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vt., Medical Association; Providence, R. I., Medical Association; Hartford, Conn., City Medical Association; Monmouth, N. J., County Medical Society (Freehold); Chicago Medical Society.

TUESDAY, *October 7th:* American Rhinological Association (second day); New York Obstetrical Society (private); New York Neurological Society; Elmira Academy of Medicine; Buffalo Medical and Surgical Association; Ogdensburgh Medical Association; Medical Societies of the Counties of Broome (annual), Columbia (annual—Hudson), Orange (semi-annual—Goshen), and Schoharie (semi-annual), N. Y.; Medical Association of Northern New York (annual—Malone); Hudson, N. J. (Jersey City), and Union, N. J. (quarterly), County Medical Societies; Chittenden, Vt., County Medical Society; Androscoggin, Me., County Medical Association (Lewiston); Baltimore Academy of Medicine.

WEDNESDAY, *October 8th:* Mississippi Valley Medical Association (first day—Louisville); American Rhinological Association (third day); New York Surgical Society; New York Pathological Society; American Microscopical Society of the City of New York; Medical Society of the County of Albany; Tri-States Medical Association (Port Jervis, N. Y.); Pittsfield, Mass., Medical Association (private); Franklin (quarterly—Greenfield), Hampshire (quarterly—Northampton), Middlesex South (Cambridge), and Plymouth (special), Mass., District Medical Societies; Philadelphia County Medical Society; Kansas City Ophthalmological and Otological Society.

THURSDAY, *October 9th:* Vermont State Medical Society (annual—Montpelier); Mississippi Valley Medical Association (second day); New York Laryngological Society; New York Academy of Medicine (Section in Pædiatrics); Society of Medical Jurisprudence and State Medicine; Brooklyn Pathological Society; Medical Society of the County of Cayuga, N. Y.; South Boston, Mass., Medical Club (private); Pathological Society of Philadelphia.

FRIDAY, *October 10th:* Vermont State Medical Society (second day); Mississippi Valley Medical Association (third day); New York Academy of Medicine (Section in Neurology); Yorkville Medical Association (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties (anniversary).

SATURDAY, *October 11th:* Obstetrical Society of Boston (private); Worcester, Mass., North District Medical Society.

Proceedings of Societies.

MEDICAL SOCIETY OF VIRGINIA.

Twenty-first Annual Session, held at Rockbridge Alum Springs, on Tuesday, Wednesday, and Thursday, September 2, 3, and 4, 1890.

The President, Dr. OSCAR WILEY, of Salem, in the Chair.

THE proceedings were opened by a prayer by the Rev. Dr. E. F. Garrison, of Philadelphia, and an address of welcome by Dr. J. Edgar Chancellor, resident physician at the Springs.

The Hunter McGuire Prize of one hundred dollars, offered for the best essay on the diagnosis, pathology, and treatment of chronic cystitis in the male, was awarded to Dr. R. M. Slaughter, of the Theological Seminary of Virginia. After the award, Dr. MCGUIRE stated that he would award another prize of one hundred dollars, at the next annual session of the society, to any practitioner residing in Virginia, West Virginia, or North Carolina, who would present the best essay upon some subject soon to be determined upon and announced by the secretary of the society.

The President's Address.—The PRESIDENT delivered an address, which was full of wit and good suggestions, and of special interest to the profession of Virginia.

The Summer Diarrhœa of Children.—A lengthy discussion was held on this subject, in which the old doctrines were maintained, with additions of whatever was valuable as the results of recent observation and research.

Officers for the Ensuing Year were elected as follows: President, Dr. William W. Parker, of Richmond; vice-presidents, Dr. J. W. Dillard, of Lynchburg, Dr. Jacob Michaux, of Richmond, and Dr. H. M. Patterson, of Staunton; recording secretary, Dr. Landon B. Edwards, of Richmond; corresponding secretary, Dr. J. F. Winn, of Richmond; treasurer, Dr. Richard T. Styll, of Hollins; chairman of executive committee, Dr. Hunter McGuire, of Richmond. To deliver the address to the public and profession during the session of 1891, to be held in Lynchburg some time in October. Dr. Charles M. Blackford, of Lynchburg. Leader of a discussion on acute dysentery during the session of 1891, Dr. P. B. Green, of Wytheville. Dr. Alfred C. Palmer, of Norfolk, was elected to fill a vacancy from his congressional district on the Medical Examining Board of Virginia.

Report on Ophthalmology, Otology, and Laryngology.—Dr. ROBERT L. RANDOLPH, of Baltimore, chairman of the Section, reviewed two important articles which had appeared in recent numbers of Graefe's *Archives of Ophthalmology* on antisepsis in the operation for cataract. The reviewer concluded, from the opposite views held by the two authors—von Graefe, of Halle, and Steffan, of Frankfort—that the former was correct, and that antisepsis, in spite of the doubt cast upon its value by the able paper of Steffan, was indispensable in cataract operations. The reporter referred to the suturing of the cornea after cataract operations, and gave the opinions of French ophthalmic surgeons. He alluded to the recent treatment of

detachment of the retina by injection of tincture of iodine. He spoke of the value of a solution of fluorescein as a means of diagnosticating corneal lesions, and concluded with a short review of the experiments of Kolinski and himself upon the lower animals—namely, the production of cataract by feeding the animals on naphthalin.

Advance in Laryngology and Otology.—Dr. William F. Mercer, of Richmond, in reporting on this subject, called attention to the conclusions of Lemon in his investigation in regard to the transformation of benign growths of the larynx in consequence of intralaryngeal operations; the early treatment of naso-pharyngeal and throat affections in young growing children as a cure or prevention of certain derangements of the nervous system and impairment of the intellectual power existing or shown later in life; nasal intubation as an easy and ready mode of cure in hypertrophy of the soft intranasal tissues, deviations of the cartilaginous septum, fractures, etc.; the easy and certain means of diagnosis of empyema of the antrum of Highmore by the illumination of the maxillary bones by an electric lamp introduced into the mouth; and the importance of perfectly free drainage in otology. He called special attention to the great importance of the early recognition of and treatment for acute suppurative otitis media following scarlatina, thereby greatly reducing the high percentage of deaf-mutism from this cause.

When shall we operate for Cataract and Strabismus in Children?—Dr. Charles M. Shields, of Richmond, read a paper with this title. He said that the text-books seemed to ignore the question, and that as a large proportion of the cases of cataract in children were of the zonular variety, allowing some vision, the operation was generally put off until they were from ten to thirteen years old, an age at which the retina had often lost its functional activity from disuse. His last five cases were cited in support of the argument for early operation. Three of them were in children between the ages of ten and thirteen, and, although the operation was successful in obtaining a clear pupil, the visual results were not very satisfactory. The two others of the series were much younger—one three years old, the other six months. Both were needled and gave the most satisfactory results. The reader thought the earlier the operation for cataract in children, the better the result, for the following reasons: First, in the young the eye was more tolerant of surgical procedures; second, the child was given all the benefit in gaining education that vision secured; and thirdly, the permanent visual results were better than would be obtained at a later age. As to the age for operation in strabismus, he thought that usually suggested (six or seven years) early enough in alternating squint, as vision in either eye did not suffer from delay; but where the strabismus was confined to one eye, the unilateral form, the earlier the patient was operated on the better. In this form of squint, vision was constantly suppressed in one eye, and amblyopia from disuse resulted, making the eye useless. The operation should be performed in the monolateral variety as early as it was recognized.

The Modern Treatment of Strabismus.—Dr. Alexander Duane, of Norfolk, presented a paper on this subject, in which he insisted upon the necessity of careful testing before, during, and after the operation. Adopting Mauthner's classification of squint into spastic, accommodative, concomitant, and paralytic, he pointed out that in the first two varieties the indication for treatment was mainly causal, while in the last two only was there the question of an operation. In concomitant squint he insisted strongly upon the difference between cases with tension and with relaxation of the tendons, and cited a remarkable case of the latter, in which an operation totally opposed to that called for by the appearances in the case had led to very striking good results. In paralytic squint he adopted v. Graefe's treatment—viz., in paralysis of a lateral rectus or an oblique muscle, tenotomy of the associated antagonist (sometimes in the former case re enforced by tenotomy of the direct antagonist or by advancement of the paretic muscle), and in paralysis of the superior or inferior rectus, advancement of the affected muscle.

Otitis Furunculosa.—A paper was presented by Dr. John Herbert Claiborne, Jr., of New York, in which he summed up his conclusions in the following way: 1. Furunculosis of the outer ear is a local disease. 2. The cause is the transmission by rough means beneath the skin of pyogenic microbes. 3. The prognosis is good, both as to the life and hearing of the individual. 4. The treatment consists in local antisepsis (solutions of boric acid, carbolic acid, etc.), moist heat, and incision of the furuncles when they point.

Catarrhal Otitis Media, or Aural Catarrh.—Dr. Laurence Turnbull, of Philadelphia, who had been invited to attend the session, read a paper which treated mostly of the results of the disease. He said, in passing, that most of the so-called hearing-restorers acted most injuriously upon the sensitive ear, and were of no benefit except to those having a hole or perforation of the drum membrane, or to those who suffered relaxation of the small bones of the ear which became sometimes separated from the membrana tympani. In many instances they had acted as a foreign body; and when they had a metal stem, as was often the case, they were sure to set up a "running ear." The only form of artificial covering to the diseased perforation of the drum membrane should be a delicate gauze or rubber, charged with an antiseptic solution, to protect the ear from the floating microbes in the air and from temperature changes. He then detailed at length a correspondence with a patient who had tried to use some of the artificial aids referred to.

A New Method of lifting the Epiglottis.—Dr. C. M. Blackford, of Lynchburg, presented a paper describing a method devised by Dr. Samuel P. Preston, of Lynchburg. The instrument used consisted of an ordinary laryngeal silver probe, with the last half inch bent so as to make a right angle with the remainder. Rings were soldered on the shaft of the probe through which the third and fourth fingers of the left hand were passed. The probe was introduced and the bent portion pressed down on the glosso-epiglottidean ligaments. This pressure tightened the ligaments and thus lifted the epiglottis. This instrument was used in the Throat Clinic in Vienna. By holding the laryngeal mirror with the thumb and forefinger of the left hand, with this elevator between the third and fourth fingers of the same hand, the right hand was left free for use. The pressure of the probe was not great enough to cause retching, and did not cause special inconvenience to the patient.

Palpo-traction.—Dr. Alfred C. Palmer, of Norfolk, introduced in a short paper a new form of treatment akin to massage which he called by this title. He stated that many distortions of the lids might be improved resulting in lasting benefit by this conservative plan. He alleged no good results unless used in infancy when the tissues were pliable and easily molded by manipulation. He asked the obstetricians to pay strict attention to the formation of the lids of the new-born, and in all forms of entropion, ptosis, contracted palpebral fissures, etc., to begin at once and shape the lids and retract them to their proper forms and positions. He also asked ophthalmologists to pay attention to this subject.

Advances in Materia Medica and Therapeutics.—Dr. I. H. Keller, of Luray, presented the report, in which he called attention to forty-three newly introduced drugs or preparations.

The Diagnosis of Pelvic Disease, or when to operate.—Dr. I. S. Stone, of Lincoln, read a paper with this title, in which he urged the importance of early recognition of cases suitable for operative treatment. He maintained that the profession was practically a unit as to the early removal of large tumors, and also as to the treatment of pyosalpinx and extra-uterine pregnancy, as the electricians evidently had the worst of the argument. There were also many cases which were not so easy to diagnosticate, but required prompt attention or they might be fatal. The salpingitis of rural districts might easily become pyosalpinx by infection with the poison of gonorrhœa. The author maintained that pyosalpinx was rare in the country for the reason given above—the comparative rarity of gonorrhœa. Salpingitis did occur frequently following puerperal diseases, but often ran its course and left no trace afterward. Its symptoms were those of pelvic peritonitis and might result in grave and alarming symptoms. The writer illustrated the diagnosis of some rather obscure cases of pelvic disease by citing cases and commenting on them, showing how often these cases were allowed to run an indefinite course when they could be promptly cured by resort to abdominal section. He also plainly called attention to the importance of recognizing the cases of neurasthenia which simulated so closely cases of real pelvic disease, but did not require any operative treatment whatever. The importance of recognizing tubercular disease of the appendages was also urged, which, according to the writer's views, were not infrequent.

Honorary Fellow Dr. George T. Harrison, of New York, in opening the discussion of Dr. Stone's paper, said there were only one or two points in it that he thought the subject of criticism, for in general it was an excellent presentation of the subject of diagnosis of pelvic diseases and when to operate. Dr. Stone had seemed to treat puerperal malarial fever as a disease of minor importance. He remarked that Dr. Fordyce Barker had been the first to draw prominent attention to this disease, which was not a rare one in certain communities. In New York, for instance, it was quite a common complication or sequel of labor. But it was not always easy to trace the development of the disease to its proper cause. It undoubtedly belonged to the puerperium. He reported a case recently under his observation in which the delivery had been conducted under the most perfect aseptic principles, and yet about a week after labor puerperal malarial fever had set in and lasted seven weeks. Rheumatism, by the way, was a frequent sequel of this fever, according to his observation.

As to the operation of removal of the uterine appendages, it had of recent months or years been very much abused. Novices, and specialists of high standing as well, were performing laparotomies with a recklessness that demanded the cry of "Stop!" He related the case of a lady who had been urged by a prominent laparotomist to have her ovaries removed for some trouble which he told her would render her an invalid for life. She declined the operation, however, and a year later became a mother. The speaker did not deny the value of the operation in certain selected cases, but he opposed this popular wholesale removal of the ovaries and appendages, and thought their causeless removal should be rebuked as severely as Baker Brown's wholesale removal of clitorides had been years ago. It should be remembered that some cases of mental derangement even had followed the removal of these sexual organs of the female. It was a difficult matter to decide when to operate, and no one should undertake the operation until after the exhaustion of every other possible means of relief—unless, of course, it was apparent that the ovaries or appendages were structurally diseased.

The matter of extra-uterine pregnancy was about the most important subject that claimed the attention of the obstetrician as well as the laparotomist. The condition was too often overlooked until it was too late to give to the patient the benefit of surgical art. The diagnosis should be made early in order that an operation might save life. Tait's pathology of extra-uterine pregnancy was all wrong. He confounded hæmatocele and hæmatoma with extra-uterine pregnancy. Hæmatocele was an effusion of blood into the peritoneal cavity about Douglas's *cul-de-sac*. Hæmatoma was an escape of blood into the folds of the broad ligament alone. But in extra-uterine pregnancy of the tubal variety, after the probable cessation of one or more menstrual periods, there was often an irregular hæmorrhagic discharge *per vaginam*, which very generally preceded rupture of the tube for several days.

Dr. Joseph Price, of Philadelphia, present by invitation, wished to emphasize all that Dr. Harrison had said as to reckless operations. Laparotomies had been too much overdone by those who had not a sufficient purpose in view. They should be undertaken only for an objective disease—not for a subjective one. More of this kind of work had been done in New York than anywhere else on this continent, and there the operation had undoubtedly been abused. Furthermore, many operations had been undertaken without having been at all well done; and such imperfect operations had brought discredit upon pelvic surgery. The time had come when simply opening the abdomen should not cause death. This was proved by the results of Dr. McGuire's operation of suprapubic cystotomy. Even the mortality resulting from laparotomies for the removal of ovarian, tubal, or uterine diseases had now become reduced to about two per cent. The speaker then exhibited some drawings of suppurating tubes by Dr. Coe, only to condemn them; they were very unfortunate and misleading. If pus could be diagnosticated in the female pelvic cavity anywhere, cut for it as you would do for a pus-cell anywhere else in the body. Extirpation of the ovaries, etc., should have no less an object in view than to save life. The day of so-called "normal ovariotomy" was past. But he would advise that all forms and sizes of fibroids be extirpated as soon as recognized. He also insisted upon the exercise of the greatest degree of caution as to intra-uterine examinations and medications. Dr. Emmet said that he had not passed a uterine sound for years. He had been called upon a hundred times to do abdominal sections to cure the results of electrical uterine applications; and the same might be said of the results of forcible, rapid dilatations of the uterine neck, and other intra-uterine procedures. Of course there were some diseases that required intra-uterine medications, but we should be very cautious in resorting to such methods of treatment. He never dilated a cervix, nor would he pass a uterine sound—he was afraid to do so. More attention should also be given to the occurrence of gonorrhœa in wives who were innocent of the thought of a wrong on the part of their husbands. The ravages of this disease among women were twice as great as those of small-pox. As to extra-uterine pregnancy, Virginia had a right to be proud of her gifts to the army of obstetrical surgeons. Bingham, of this State, about a hundred years before, had done the first scientific operation for extra-uterine pregnancy, and about nine years later a second one.

Honorary Fellow Dr. Hunter McGuire, of Richmond, remarked that Dr. Harrison had said that Dr. Fordyce Barker had been the first to call attention to and name puerperal malarial fever. But it was the late Dr. Otis F. Manson, of Richmond, who had first described and designated the condition, and now Dr. Barker recognized this claim of priority. Dr. Price had said that the man who employed a sound or made intra-uterine medications ought to have his head shaved. If the speaker had had a strand of hair removed for every one he had made, he

said that he wonld be bald-headed. Dr. Battey was a good man and a great surgeon, and was the pioneer in important gynæcological work; bnt Battey's operation of normal ovariotomy would become obsolete. In the speaker's opinion, it was a crime to take out normal ovaries for any nervous or hysterical condition. Some years ago he had done it, but he regretted it; it did no permanent good. When there was some pathological change in the ovaries or tnbes, then, after failnres by other means, the operation should be done; bnt all other means shonld be first exhansted. He himself had obtained mnch good in such cases from the nse of galvanism. He did not agree with Dr. Price that all fibroids should be removed. In nine ont of ten cases that came to him, he advised the patient to let the tnmor alone. If the growth was stationary or nearly so, giving rise to no pain or mechanical obstructiou, he would let it alone. If the gentleman knew how common fibroids were among negroes, and how many negro women were working to-day with fibroids of the uterus, in no way disabled for work by the tumor, he would not advise operation in all cases.

Dr. Joseph Hoffman, of Philadelphia, present by invitation, remarked that not many years ago every surgeon was sewing up perinænms and nterine cervices. Bnt Emmet arose and protested against such procedures. The speaker said that Battey's operation had been given a fair test and had failed, and should hereafter be done away with. Others thonght that all diseases of women were essentially cellulitis; but in ninety-nine cases out of a hundred this was a mistake. Tait had only revised the pathology of forty years ago, and evidently got it from Nonat, who fully discnssed the subject as a circnmuterine and lateral phlegmon about 1846. Snrgery onght to be resorted to in these cases only for the purpose of relieving pain or else to save life. Many had punctured pelvic abscesses in the hope of curing them. but they had never been thns cured. To open one pns cavity in the tnbes did not empty all the reservoirs of pus, because these tubal pus cavities were like links of sausage. Hæmatocele was very rare. Mr. Tait said when it did occur it was often mistaken for extra uterine pregnancy. Exploratory incisions should he used only as guides to the surgeon to see whether or not he could cure a given case. One shonld never cut down upon an abscess or a tnmor in the abdomen, and half finish the operation. Such half-finished operations injured surgery in the esteem of the profession as well as the people. Scraping the mncous surface of the uterus with curettes, etc., was bad practice. Laparotomies had been shown to be comparatively devoid of danger nnder modern modes of procednre; so when such operations were required, operate early. Undoubtedly the snrgeon should exercise common sense in selecting his cases for laparotomies as for other operations, and there could be no question as to the abuse of this operation by many surgeons—by some, even, of great eminence. But because an operation was abnsed by some it was not totally unjustifiable in certain cases.

Dr. Edwin S. Ricketts, of Cincinnati, present by invitation, confined his remarks to a review of the history of ovariotomy and abdominal sections generally—suggested by the fact that the society was now meeting within a few miles of the birthplace of the immortalized McDowell in this (Rockbridge) county. Bringing his subject down to the present time, he thought that now the operations of opening the female pelvic abdomen were too hastily undertaken by surgeons who sought rather to make reputations for daring than to save the lives of their patients. Discredit came upon surgery whenever an operation was undertaken without a previous diagnosis and a consideration of the points which determined prognosis. He hoped the profession would frown down such reckless surgery, and keep surgery always lifted upon the platform of humanity, such as had prompted McDowell to nndertake the first ovariotomy and such as would ever make the profession commend it to their patients.

Dr. Isaiah H. White, of Richmond, spoke of the importanc of an early diagnosis and prompt removal of an extra-nterin pregnancy. The doctor generally knew nothing about the dan ger just ahead nntil the snddeu collapse aud other evidences o ruptnre of the tube indicated too plainly that his patient wa dying from rupture of an extra-uterine gestation sac into th peritoneal cavity. Bnt if snch a state of things passed by an the woman rallied and got well of the effects of such a ruptnre or if gradual extrnsion of the fœtns from the tube so occurre as never to lead the surgeon to know where rupture was, an if the fœtus became encapsulated in a new sac, etc., the extra uterine pregnancy might remain for years in a qniescent state the fœtus being dead, and no apparent risk of life of the patien occurring by reason of snch extra-uterine pregnancy. He ha known a case where an extra-nterine pregnancy had remaine indolent for years, nntil finally a normal intra-nterine impregn tion occurred. Many cases were reported where the diagnosis c extra-uterine pregnancy had been first made by the ulceration c fœtal bones through the rectnm, etc., the pregnant conditio years before not having been more than suspected at the tim and the idea dismissed by both patient and friends because c the recurrence of the apparently normal menstrnal functio Such cases suggested that, in cases of snpposed or diagnostica ed extra-nterine pregnancy, before ruptnre of the tubes int the peritoneal cavity, if the mother wonld not consent to ope ation, the fœtus shonld be killed by galvanism; then the ovu might remain in its sac simply as an innocent foreign bod The known laws of accommodation on the part of natnre t gradually developed abnormal conditions might lead to th final safe removal of the fœtns piecemeal, by self-protecti nlcerations throngh the rectnm, etc. Hence it was yet a fie for discussion as to the propriety of always insisting npon a operation for an old extra-uterine pregnancy. But when a operation was decided on, what were known as the "rem nants" of an extra-uterine conception, exclnding the fœt itself, were most probably altogether the products of the i flammatory action set up at the time of the passage of the fœt through the tube into the peritoneal cavity. The strictnre portions of the pus-tube, which gave that canal the appearan of rolled sausage, were dne to adhesive perimetric ban formed around the tube. As to the so-called "normal ova otomy," Dr. McGuire had deplored the results obtained by hi Undoubtedly he was correct. In fact, it might not be too mu to say that some of the survivors of the operation regretted th they were alive.

Dr. Landon Carter Gray, of New York, present by invi tion, said that the further resort to "Battey's operation" and t like for the cure of nervous diseases would be a crime. Years a Baker Brown had properly been expelled from the professi because of his useless clitoridectomies. The great name of L Sayre, a short while ago, had given authority for unnecessa circumcisions for the relief of some nervous troubles. Steven wholesale cutting of eye muscles for the treatment of chor and other nervous diseases should likewise be condemn No snch operations should ever be considered panaceas, a they should not he undertaken except when there was a clea defined requirement for them other than the simple nerv trouble. In almost all the cases where such mutilations l even apparently done good, such relief was of only tempor duration, showing that the supposed cure was in reality the sult of a psychological actiou. "Normal ovariotomies" had questionably appeared to do good in a small proportion of stances upon this very principle; but in all the cases so opera

on that had come under his observation, the attacks had returned with even greater severity than the original sickness. As long ago as 1828 this principle of mental impression was put to a thorough therapeutic test by Esquirol, and the results of his experiments should be kept ever before those of the profession who still insisted upon experimental operations. He divided his cases of epilepsy, etc., into groups. To one group he gave one class of remedies, with the addition of strong mental encouragement. To another group he gave another class of medicines, with the same encouragement as to the benefit to come from the "new treatment." To another group he gave another class of remedies, etc.; while to still another group he gave simply colored water, etc. Each group of cases did equally well for a season, but relapses soon began to occur, and all the patients fell back to the former degrees of sickness. Up to the present time no remedy had stood the test of prolonged experience in epileptic forms of diseases, unless it was the bromides. Undoubtedly operations had been most beneficial when performed upon the strongly impressionable class of patients; but this very fact confirmed the suggestion that most probably one operation would do about as well as another. If this was so, then, in the name of humanity, whatever might be the amount of impression that you wished to leave upon your patient, perform that operation which was least serious in its possible results of unsexing the individual, or otherwise mutilating her. To make a simple incision somewhere, and yet let the patient believe that a severe operation had been performed, would do as much good in most cases as the real operation.

Dr. William W. Parker, of Richmond, could not understand why all this hue and cry had been raised of late years about the danger of ordinary uterine treatment, unless it was another case of the cry of authority against every-day experience. Of course, judgment and gentleness were as essential in such treatment as anywhere else. He believed intra-uterine injections were perfectly safe, if the precautions usually recommended were faithfully observed. In a large practice daily since the war he had used them without ever hearing of harm resulting.

Dr. Harrison said that he would not have himself recorded as *in toto* opposed to Battey's operation, for there were troubles of a serious nature that he had seen relieved, if not cured, by "Battey's operation" for apparently moderately diseased ovaries. But Dr. Battey's original error—which, however, had since been corrected—consisted in naming his operation "normal ovariotomy." He thought Dr. Battey justly entitled to the credit of having pointed out a new and important gynæcological field for thorough study.

Dr. Stone, in closing the discussion, thought it proper to remark that Dr. Barker's puerperal malarial fever was often nothing but the evidence of the existence of pus in the Fallopian tubes. He would not, however, undertake to deny that there was a pure puerperal malarial fever, as Dr. Manson had described prior to Dr. Barker's mention of the subject. As to Battey's operation, he had never done but one, and the result was unsatisfactory. Hence he stood simply as an interested listener of the remarks that had been made by practitioners of such large experience and extensive reputation, whose dicta would go far in shaping or establishing subsequent professional opinion on the subject.

Vertigo was the title of a paper read by invitation by Dr. Landon Carter Gray, of New York. He stated that there was a vertigo due to organic disease and a vertigo of functional nature. An important generic distinction between these two was that organic vertigos were accompanied by less irritability and apprehension on the part of the patient than were the functional ones. If of organic origin, the vertigo must proceed from disease of some one or more of the abdominal or thoracic viscera, the spinal cord, the intracranial organs, or the ear. Examine the urine always repeatedly both chemically and microscopically for albumin and casts and test the arterial pressure by sphygmographic tracings. But the speaker's observation showed that kidney, heart, and organic liver troubles caused slight vertigo, lasting only a short time. In renal vertigo there was usually a headache that had at times a tendency to hebetude or coma; occasionally there were convulsions and general or local œdema. In hepatic vertigo there would usually be some degree of hebetude or jaundice or dropsy. Almost all intracranial lesions would cause vertigo, which, in certain of them, would be pathognomonic. For instance, cerebellar lesion would produce a swaying, staggering gait, called titubation, or the patient would stagger markedly to one side, or he was suddenly whirled in a semicircle. If Dr. Dana's observations proved correct, temporal-lobe lesions might produce similar symptoms. Spinal-cord diseases were not apt to cause more than slight vertigo, with the exception of certain cases of locomotor ataxia, where dizziness was common when the patient was standing with his eyes closed. Aural diseases, especially of the middle ear or labyrinth, also often caused vertigo.

But the form of vertigo which caused most distress was chronic, coming on in sudden paroxysms, varying from a sudden, uneasy sensation of loss of equilibrium to such uncertainty of gait as to make the patient dread going out in the street and frequently accompanied by symptoms of other nervous disturbance, such as furriness and tingling of the extremities, a feeling of distention or fullness about the head, usually at the vertex, with slight ringing in the ears, a certain irritability and nervousness, and often a mild degree of insomnia. It was rare in children, not infrequent in the elderly, but was most frequent in young and middle-aged adults. This vertigo was extremely obstinate, often lasted for years after the attending nervous symptoms had disappeared, or it might be the only symptom throughout. It was prone to occur in northern climates in the first warm months of the year, and severe cases occurring at this time did not begin to recover until after cold weather had set in. It was made worse by heat and temperature alternations; in extreme cases, even going from a cold into a heated room would cause attacks. Nervous prostration was common—a form of neurasthenia. Generally the tongue was unaffected. The urine usually contained uric acid or oxalate of calcium. The cause of this symptom-group was a matter of discussion. The older writers treated of it as a stomach vertigo, but Murchison thought it due to liver derangement, producing excess of uric acid; hence the name he gave it—lithæmia. The speaker was not satisfied with this explanation, for many cases did not present a tangible evidence of hepatic derangement, nor had we ever established a standard by which we could say what was an excess of uric acid; besides, in some cases, the uric acid had been extremely small in amount; and again cholagogues, such as calomel, aggravated the vertigo, and often the nervous symptoms also. He had now come around to adopt the old theory, that the vertigo was of gastric origin, including the entire digestive track. The majority of cases of this peculiar form of vertigo were due to some chronic and persistent error of digestion, either of the nitrogenized or starchy elements of food, or of both. Constipation without coated tongue or foul breath was common in this error of digestion. It occurred in those personally or hereditarily predisposed to gout or rheumatism. The exciting causes were, however, mental or physical overwork, great anxiety, malaria, or a very sedentary life. For therapeutic purposes he grouped his cases with this form of vertigo into (1) those in whom the general neurasthenia was slight, and (2) those in whom it was severe. In the non-neurasthenic cases, begin with twenty drops of dilute nitromuriatic

acid before meals in a wine-glass of water and one drachm of fluid extract or two grains of solid extract of cascara sagrada three times daily. Take this amount of cascara continuously, reducing it if it produces more than two feculent actions a day. During the same period interdict the red-meat diet entirely. The patient would feel less dull, have less of the sense of distention of the head, and feel generally better, although the vertigo would probably be unaltered. After about ten days stop the acid and give pepsin and pancreatin, the pepsin immediately after meals and the pancreatin an hour and a half after. This treatment would more generally relieve the vertigo than anything else he had tried. After a time gradually restore the meat, but only once a day. In the neurasthenic cases his treatment was the same, with the addition of rest, in rare cases putting the patient to bed for two or three weeks. It was better to err on the side of enforcing too much rather than too little rest. In differing so radically from others on this point, he had only to say that his experience had taught him to so differ.

Dr. William W. Parker agreed with Dr. Gray that the chronic vertigo described was of dyspeptic origin, and hence recommended rigid diet.

Dr. Hunter McGuire said that the cases of vertigo so well defined by Dr. Gray were due to lithæmia, and originated in some derangement of the portal system. If the liver acted well—to use the common expression—the vertigo did not occur. But inactivity or a deranged action of the liver was not always shown by a furred tongue, etc., for that might be red and moist, while the fæcal discharges were grayish or puttyish. But there was always some evidence of gastric or bowel fermentation, as shown by greater or less eructations an hour or two after eating. Acting upon the suggestion thus derived, he had got benefit from the following plan of treatment: Use a good cholagogue for two weeks or so, so as to get one or two feculent actions a day; and then give for about a month, three times daily, just after meals, minute doses of corrosive sublimate—from one sixtieth to one eightieth of a grain—in solution or pill. Afterward give a perfectly neutral solution of the hypophosphites of lime and soda after each meal. The syrups of the hypophosphites as found in the shops were injured by the amount of sugar they contained.

Dr. Isaiah H. White was satisfied that the form of vertigo described was due to lithæmia or to some of the waste products of digestion that were not properly eliminated. Possibly ptomaines developed.

Mr. Hugh Blair, of Richmond, fraternal delegate from the Virginia Pharmaceutical Association, had long since come to the conclusion that this was a lithæmic vertigo. Evidences of impaired portal circulation and function were always found in such cases. Lithæmia was but another expression for the gouty disposition, and was due to disordered or fermentative digestion.

Permanent Drainage of the Male Bladder by a Retained Cannula introduced above the Pubes.—This was the title of a paper read by Dr. George Ben. Johnston, of Richmond. He said that Dr. Van Buren had devised the best instrument for the purpose that he knew of—consisting of an outer cannula, an inner tube, and a trocar. After quoting descriptions of these, Dr. Johnston stated that he had added to the instrument a steel guide, of double the length of the trocar, over which the outer cannula might be easily drawn out of the bladder and replaced without fear of losing its course. After describing the simple operation of opening the bladder above the pubes, and how to retain the instruments, he remarked that both acute and chronic cases were benefited by the proposed treatment. Conditions so benefited were urinary retention, injuries of the urethra or prostate, acute prostatitis, perineal abscess, urinary extravasation, coagula in the bladder, chronic cystitis, enlarged prostate, or cancer of this gland, or of the bladder, urinary fistulæ, sacculations, adynamia, etc.

The Present Status of Abdominal Surgery.—Dr. Joseph Price, of Philadelphia, Pa., read a paper on this subject.

Early Exploratory Incision as an Aid to the Diagnosis of some Surgical Diseases of the Abdominal Cavity.—Dr. Edwin Rioketts, of Cincinnati, read a paper on this subject. He had found it difficult in many cases to make a diagnosis previous to exploratory incision. To open the abdomen was easy enough, but afterward to do always the best thing and that promptly, knowing when to end at exploration, bearing in mind that half-completed surgical procedures are rarely ever excusable; these were of greatest consideration.

Nervous Disorders following Organic Stricture of the Urethra.—Dr. Hunter McGuire read a paper thus entitled. He related a number of cases in which paralysis, apoplexy, or cerebral disease of some kind had followed long-standing stricture. In none of these cases was there renal disease. In his practice he had seen sclerosis of the lower portion of the spinal cord follow old strictures. He concluded the paper thus: Are all of these cases mere coincidences? Urethral strictures are so common, and diseases of the nervous center so frequent after middle life, and the interval of years between the formation of the strictures and the appearance of nervous troubles so great, that it is difficult to say that one is dependent upon the other. As it is, however, I can not help thinking that long-existing urethral strictures may set up reflex irritation in one or more of the nervous centers, and, this persisting, ends in pathological change in one form or another.

The Salient Points in Appendicitis; its Diagnosis and Treatment, was the subject of a paper read by Dr. Joseph Hoffman, of Philadelphia.

Remarks upon Anteflexion of the Uterus was the title of a paper read by Dr. George Tucker Harrison, of New York. The normal position of the uterus in the erect woman, when the bladder and rectum were empty, was that of anteversio-flexio, the place of flexion being at the junction of the cervix and body. But when the bladder was distended, the uterus was lifted up physiologically and its posterior wall lay in juxtaposition with the anterior wall of the rectum; it was both retroposed and retroverted. While the bladder was being emptied, the fundus uteri described an arc which corresponded to an angle of from 45° to 60°. The characteristic feature of pathological anteflexion was simply the stability of the flexion. The causes which made the flexion permanent were either in the organ itself or operated on it from without. Metritis or infarction belonged to the first class of causes, while parametritis posterior, parametritis chronica atrophica, and perimetritis belonged to the second and more frequent class of causes, and were more permanent in effect. When metritis attacked an anteflexed uterus, the angle, which up to that time had been variable, became fixed. The symptoms usually associated with anteflexion were dysmenorrhœa and sterility. This painful dysmenorrhœa was not mechanical, but was due to the associated metritis. The sterility also was attributable to the accompanying endometritis, oophoritis, and perimetritis. If these inflammations were removed, and if the perimetritis had left no permanent pathological changes, conception might ensue, notwithstanding the existence of parametric cicatricial tissue or permanent anteflexion. The diagnosis of this pathological anteflexion depended alone on the demonstration of the stability of the flexion. Bimanual palpation, or the establishment of the fact that the anteflexion persisted even when the bladder was distended, or the discovery that the folds of

Douglas's sac were shortened or thickened, were the means for deciding as to the stability of the flexion. As to treatment, it was of prime importance to try to remove the parametritis posterior, or perimetritis and results. If the uterus was supersensitive, scarify it just prior to menstruation, and the dysmenorrhœa would be moderated. For the persistent uterine catarrh, wash out the uterine cavity with a solution of carbolic acid after dilatation with aseptic laminaria tents, followed by steel dilators. Lately he had been very much pleased with ichthyol, incorporated with lanolin, applied around the portio vaginalis, in clearing up old perimetric and parametric adhesions.

Epilepsy.—Dr. M. D. Hoge, Jr., read the Report on Advances in Neurology, confining his remarks more especially to this disease. We were perhaps more indebted to Hughlings Jackson for the clearest explanation of convulsions than to any medical writer of recent date. Three classes of convulsions were made, corresponding to the three levels of the nervous system. An epileptoid seizure was due to the high instability of certain cortical cells, produced by the nutrient fluid bathing the cells becoming comparatively stagnant, and in consequence there was inferior nutrition, a "substitution nutrition," whereby the phosphorus compounds became more nitrogenous, or *vice versa*. What was the best form, then, of food for the nerve cells? Seguin had stated that the central nervous system and peripheral nerves were largely made up of fatty substances. In the ash of the cerebral substance the phosphates existed to the extent of 93·5 per cent.

Dr. J. D. Eggleston, a fellow of the society, had come nearest to the question of a cure for epilepsy, and to him the writer was largely indebted for the following method: The treatment was a combined one, partly direct and partly symptomatic. The first step was to supply the brain with proper food; this could best be accomplished by the use of cod-liver oil, combined with the hypophosphites of calcium and sodium, and a diet consisting largely of fatty food was enjoined. Every source of external irritation must be carefully looked into and corrected; it might be eye-strain, nasal polypi, malpositions of the uterus, or phimosis. Remove these sources of constant irritation, which were continually sending nervous impressions to an anæmic brain, and, there accumulating, it became surcharged, its equilibrium was disturbed, and a nervous explosion—an epileptic fit—took place.

No specific power could be ascribed to atropine. The chief benefit to be derived from its use was the paralyzing effect it had on the whole muscular system. The spasmodic contraction at the throat and the violent movements of the body during a convulsion were, in a great measure, controlled. Another important effect produced by its use was the time between the aura and the convulsion itself was long enough to allow the patient to lie down or take some sedative.

The use of bromides could not be dispensed with entirely at first. The patient must carry in a convenient pocket by day, or under the pillow at night ready for instant use, a solution of bromide of sodium ten grains, chloral hydrate five grains, to the drachm. It should be immediately swallowed whenever the aura was felt, a slight fainting sensation, or any vague fear of an impending attack.

The treatment which gave the best results in epilepsy was a combined one, nutritive, antispasmodic, and sedative, represented by cod-liver oil, atropine, and bromides.

Removal of a Large Vesical Calculus per Vaginam.—Dr. E. M. Magruder, of Charlottesville, reported a case. The stone was about two inches by three inches, and had caused a fistulous opening of about five eighths of an inch in diameter in the vaginal wall. He reported the steps of the operation adopted for its removal by enlarging the vesico-vaginal opening, and, as the stone seemed adherent, pieces of it had to be removed at a time, instead of by lifting it out of its pouch.

Honorary Fellows.—Dr. L. Ashton, of Falmouth, received the unique and unanimous compliment of election as honorary fellow of the society without ever having been president. In numerous ways he had rendered most valuable services to the society, and, as he was about to leave for Dallas, Texas, it was a fitting expression of the esteem in which he was held by the Virginia profession to so elect him.

The retiring president, Dr. Oscar Wiley, was also elected an honorary fellow.

RICHMOND, VA., ACADEMY OF MEDICINE AND SURGERY.

Meeting of September 9, 1890.

The President, Dr. W. W. Parker, in the Chair.

(*Reported by Dr. J. W. Henson, Richmond.*)

Simple Ulcer of the Rectum was the subject for discussion, in the opening of which Dr. Louis C. Bosher read a paper in which he said that he had selected this subject, not with the intention of writing a lengthy paper, but simply to report a very interesting and troublesome case of this disease that had fallen into his hands last year. In October last he was called to see a young married lady who was suffering intensely from a persistent diarrhœa and nervous prostration. She had become very much emaciated and was very anæmic. He had learned that she had been a sufferer for eight or ten months from diarrhœa, and during that time had lost some forty or fifty pounds in weight. She had told him that she had received treatment from a number of physicians, one of whom had informed her that she had a chronic diarrhœa and was beyond the control of medicine, and another that she had consumption of the bowels, and intimated that it was only a question of time.

When the speaker saw her she had just returned from one of our alum springs, where she had been constantly under the care of a physician. To complicate matters, a pelvic abscess had formed during her stay at the springs, and had broken before she reached home. Under this double drain on her system she had wasted to almost a skeleton, and had become completely bedridden. The abscess had discharged quite freely *per vaginam*, but finally, under active treatment, had ceased with an improvement in her general health. The diarrhœa, however, had continued off and on, notwithstanding the free use of remedies. The patient had now begun to complain of a slight protrusion and of a smarting, with an unsatisfied feeling whenever she went to stool. She had also complained of a dull, aching pain at the end of the backbone. After the development of the above-named symptom the speaker had made an examination of the rectum with the rectal speculum. When the sphincter was slightly dilated there was a slight discharge of pus and mucus from the bowel. On withdrawing the blades of the speculum somewhat, an ulcer was discovered, about an inch and a half in diameter, occupying the anterior wall of the rectum just above the internal sphincter. The speculum was then removed, and, by inserting the finger into the vagina, the bowel was turned outward, bringing the ulcer fully into view. After cocainizing the ulcer and slightly scraping it, he had made an application of nitrate of silver.

When he saw the patient on the following day he was informed that the dull pain in the lower end of the backbone was very much improved, and that there had been only one movement from the bowels in twenty-four hours, and this one had been unaccompanied with the usual rectal tenesmus. Previous to the discovery of the ulcer and the application of silver,

there had been from three to six movements in twenty-four hours. This treatment was repeated at intervals of five or six days for some little time before the ulcer healed. The diarrhœa had now been absent for some six or eight months, and, although she was very emaciated and anæmic, she was doing very nicely and was enjoying a stay in the mountains.

He had reported this case for two reasons—firstly, to emphasize the importance of diarrhœa as a persistent symptom in some forms of rectal ulcer; secondly, to call attention to the long train of nervous symptoms which had followed its presence, and which, with the diarrhœa, had been entirely relieved by removal of the cause.

During her confinement to bed this patient had been the subject of constant attacks of hysteria. She was now comparatively free from all hysterical symptoms.

Allingham, in his work on the rectum, said: "Ulceration of the rectum is not an uncommon disease. It inflicts great misery upon the patient, and, if neglected, leads to conditions quite incurable. As the earlier manifestations are fairly amenable to treatment, it is of the utmost importance that the disease should be recognized early. Unfortunately, it rarely is so, the symptoms are obscure and insidious, the suffering at first but slight, and thus the patient deceives not only himself but his medical attendant."

Now, what were the symptoms of this affliction and what the causes producing it? Diarrhœa was an early symptom, occurring early in the morning—frequently as soon as the patient got out of bed. There was a most urgent desire with an unsatisfied feeling, requiring the patient to remain long at stool. A dull, aching pain located at the end of the backbone was another symptom.

Blood, sometimes mixed with pus and mucus, often escaped from the rectum. When the ulcer was complicated with a fissure in the anus the most intense suffering, often lasting for hours, would occur, especially after stool. Pruritus ani caused by the ichorous discharge from the ulcer was another very annoying symptom. So blood poisoning of the different organs of the body might occur when the ulcer had begun to break down, and, in its destruction of tissue, pus, mucus, and impure blood were excreted.

Prominent among the causes of rectal ulceration was catarrh of the rectum, or proctitis, which might be brought on by exposure to cold, sitting on cold surfaces, etc. So the lodgment in the bowel of fish or chicken bones, fruit stones, buttons, seeds, pins, etc., which had been accidentally swallowed, might set up severe forms of ulceration. Operations for hæmorrhoids and accidents in childbirth, too, might be numbered as among the causes. Constipation, the fæcal masses tearing the delicate mucous membrane of the rectum, was not an infrequent cause of ulceration. In the first edition of Kelsey *On Diseases of the Rectum and Anus*, he said: "It is much easier to give a lady a diarrhœa mixture and trust in Providence for a cure than to gain her consent to take ether and be thoroughly examined, and for this reason many a case of curable disease has been allowed to reach an incurable stage before its existence has been certainly determined. The existence of a chronic diarrhœa or of a discharge of any kind from the rectum is always a good and sufficient reason for a thorough physical examination, and with ether, a dilated sphincter, and a good speculum no one need be in doubt as to the existence of ulceration in the lower part of the rectum."

Would it not, then, be well in chronic forms of diarrhœa, failing to be relieved by the usual recognized treatment, to make an examination of the rectum with a speculum and exclude ulceration before pronouncing our patients the subjects of incurable forms of diarrhœa?

The President mentioned a woman who had recovered from a rectal ulcer three inches long.

Dr. J. S. Wellford thought that Dr. Bosher had made a good suggestion. He was sure that many cases of chronic diarrhœa and so-called chronic dysentery with great prostration were due to rectal ulceration and could be cured by the line of treatment suggested. As illustrative he reported two cases of abscess about the rectum and one case of rectal ulcer. One of the former had been particularly interesting because the patient had lost five or six ounces of tissue, the anus had been completely denuded, and the end of the rectum detached and hanging out, yet he had recovered. In one of these cases the speaker had been struck with the fact that the bismuth which had been given for the diarrhœa had continued to pass ten days or two weeks after its administration had been stopped. He therefore had no confidence in bismuth except as a protective in irritation, since it merely adhered to the bowel and was not absorbed. He also stated that it was not necessary to dilate in females, particularly if the parts were relaxed from age or often-repeated parturition; the finger in the vagina could readily turn out the rectum. Dilatation was best in the male to paralyze the sphincter.

Dr. Landon B. Edwards was desirous that other remedies be suggested for simple ulcer of the rectum in case the caustic treatment failed, as it sometimes did. He suggested bismuth and iodol (or iodoform) in equal parts. He had relieved a man by that treatment in about a month and a half or two months when he had run the gantlet of twenty-six doctors before reaching him. He stated that simple ulcer of the rectum was not common.

The President had seen Dr. Hunter McGuire cure a case absolutely by diet.

Dr. T. J. Moore had gained a valuable hint from the last-named case in the treatment of two cases of his own. The first was a man who, being told he had cancer of the rectum, had become positive that his bowel was so constricted that he could not get up a simple enema and that he only passed at stool a few drops of mucus through the muscular action of the bowel. He really had fourteen to twenty actions a day, and, while fæcal matter was there, yet the consistency was for the most part blood and mucus.

The speaker had convinced him of the absence of the constriction by injecting a quart of water, though the man had imagined it was running back into the basin. An examination had showed the whole of the lower part of the rectum excoriated. By a diet of stale bread and milk, and bismuth and salicin (internally) as medicines, he had been cured. He mentioned another case, a constriction complicated by an ulcer just above it. Dilatation and diet had effected a cure. He recommended (in males) salicin and bismuth internally and no local interference as a rule. Where the trouble involved the internal sphincter, dilatation by the thumbs was indicated. Here nitrate of silver seemed almost specific in healing and relieving pain. Iodoform very frequently relieved pain and spasm for a few hours. He mentioned a case in which for that purpose he had used it with marked success in suppositories.

Continued Fever.—The President stated that the young man whose case he had reported at the last meeting as resembling typhoid was still sick. He had complained of severe headache all along, and he had a dull look about the eye. The speaker was afraid of head trouble. The temperature had kept up from 101° to 103°. Dr. John R. Wheat, in whose charge the patient had been left for a while, had given full doses of quinine every morning, but without relieving the fever. His pulse was weak, but the skin was always moist and cool, tongue clean and moist; also he had a good appetite. At his

request he had been allowed some soft eggs on Tuesday last, but they had acted on his bowels and had to be stopped. There had been for some days a too free discharge of high-colored urine—one quart in six or eight hours. It was acid, but contained no albumin or bile. There had been no tympanites from first to last, nor any approach to it. The prostration and emaciation were marked.

He took plenty of liquid food, large quantities of milk among other things, to keep up his strength. Was this typhoid? The speaker thought it was.

Dr. EDWARDS had searched the literature to get light upon the above class of fever. In volume i, Pepper's *System of Medicine*, he had found it described as "simple continued fever" by Hutchinson. There was not the dry tongue, the eruption, the decided tympanites, or the other characteristic symptoms of typhoid fever. Any solid food whatever would raise the temperature. Purging could be done without damage. He had a case now which had run sixty days. First the patient had typho-malarial fever, recovering in about fifteen days. Later on this continued fever had begun. He was now convalescing, but had a considerable urethritis, for which no cause could be assigned.

Dr. WELLFORD thought the amount of fever would account for the highly colored and acid urine as well as its high specific gravity (referring to Dr. Parker's report), and the amount of milk and other liquids taken would account for the quantity of urine.

The speaker called this continued fever typhoidal because, while it lacked most of the characteristic symptoms of typhoid, yet it resembled the latter in the prostration present and the continuous fever. He believed it was typhoid. It reminded him of typhoid in children where, owing to the non-development of Peyer's patches, etc., most of the characteristic symptoms were lacking. Dr. Coleman had said that any fever in children running over twenty-five or thirty days and not controlled by quinine was typhoid.

Dr. MOORE thought the nature of this fever would the sooner and better be learned if every doctor would arrange to obtain the temperature of such patients twice a day, say between 7 and 9 A. M. and between 4 and 6 P. M. The more general knowledge of the thermometric variations in this fever thus gained would materially assist in the diagnosis of it.

The PRESIDENT suggested that, as the greatest prostration always occurred between 2 and 4 A. M., the temperature should be taken then as well as at the hours suggested by Dr. Moore.

Miscellany.

The Mississippi Valley Medical Association will hold its sixteenth annual meeting in Louisville on Wednesday, Thursday, and Friday, October 8th, 9th, and 10th, under the presidency of Dr. J. M. Mathews, of Louisville. Besides the president's address and an address by Dr. J. A. Wyeth, of New York, the programme contains the following items: On Infectious Dyspepsia and its Rational Treatment by the Antiseptic Method, by Dr. Frank Woodbury, of Philadelphia; Help and Hindrance to Medical Progress, by Dr. John H. Hollister, of Chicago; Therapeutic Uses of Cardiac Sedatives in Inflammation, by Dr. H. A. Hare, of Philadelphia; Mechanical Obstruction in Diseases of the Uterus, by Dr. George Hulbert, of St. Louis; The Construction of Bacteria, by Dr. J. T. Whittaker, of Cincinnati; A Fatal Case of Vomiting after Laparotomy, by Dr. T. A. Reamy, of Cincinnati; The Surgical Treatment of Uterine Fibroids, by Dr. R. Stansbury Sutton, of Pittsburgh; Fracture of the Lower End of the Radius, by Dr. P. S. Conner, of Cincinnati; Coffee, its Use and Abuse, by Dr. I. N. Love, of St. Louis; Treatment of Fracture of the Forearm by Extension, Counter-extension, and Fixed Supination, by Dr. X. C. Scott, of Cleveland; Flint's Doctrine of the Self-limitation of Phthisis, by Dr. William Porter, of St. Louis; Cough, its Relation to Intra-nasal Diseases, by Dr. A. B. Thrasher, of Cincinnati; A Case of Rhinoplasma—Operation, by Dr. A. H. Ohmann-Dumesnil, of St. Louis; Chronic Diseases of the Joints, by Dr. Joseph Ransohoff, of Cincinnati; Cases of Penetrating Stab Wounds of the Abdomen, Laparotomy Results, by Dr. H. C. Dalton, of St. Louis; Gastro-enterostomy, by Dr. George Cook, of Indianapolis; Torsion of Arteries as a Means for the Arrest of Hæmorrhage, by Dr. J. B. Murdock, of Pittsburgh; The Psychic Sequences of an Entailed and Chronically Acquired Alcoholism, by Dr. C. H. Hughes, of St. Louis; A Résumé of Experience to Date all over the World in the Various Operations for Cystitis from Prostatic Hypertrophy, by Dr. W. T. Belfield, of Chicago; Fevers and their Treatment, by Dr. C. G. Comegys, of Cincinnati; Bromide Eruptions resembling Syphilitic Lesions, by Dr. W. T. Corlett, of Cleveland; Original Investigation in Medicine in the United States, by Dr. Frank S. Billings, of Chicago; Acute Ascending Paralysis, by Dr. Joseph Eichberg, of Cincinnati; Inguinal Colotomy, with Report of a Case, by Dr. Arch Dixon, of Henderson, Ky.; One Danger that Threatens the Physical Deterioration of the Whites in America, by Dr. E. An Opium Pill for Dysentery.—Dr. N. M. Geer, of Toronto, O., sends us the following formula:

℞ Pulv. opii..... gr. xx;
Pulv. resinæ..... gr. xxx;
Pulv. acaciæ..... gr. xx;
Aquæ..... q. s.

M., fiat massa in pilulas No. xxv dividenda.

S. One pill every four hours until relief is obtained. Dr. Geer says that he uses this pill with great success in obstinate cases of dysentery, and that the resin prevents the pill from dissolving before it has been carried low in the intestine. Old opium pills, that have become difficult of solution, are used by some practitioners with the same idea in view.

Aristol in Acne Indurata.—Dr. William Wickham, of Youngstown, O., writes as follows: The therapeutical agents recommended in cutaneous affections are numerous, but many of those used locally are objectionable for reasons well known to the dermatologist. Good local applications are very necessary, and in almost all cases, owing to their parasitic origin, are indispensable adjuncts to the general treatment. Among the best, according to my experience, is aristol. Having a case of acne indurata which stubbornly resisted the usual treatment, I concluded to use the new remedy, aristol, prescribing it in the form of an ointment of the strength of ten per cent. made with benzoated lard. It was applied at bedtime after having washed the surfaces affected—*i. e.*, the face and neck—with strong soap and hot water. In the morning the surfaces were again washed for the purpose of cleanliness. The ointment was applied every night as at first, and in about two weeks I dismissed the patient as cured. It is now several months since, and no return of his old trouble has occurred. I would add that I am now using aristol in the treatment of chronic eczema with gratifying results.

The Poisoned Arrows of the African Pygmies.—"From the pages of *In Darkest Africa* we learn that the poisoned arrows of the pygmies in the forest often made great havoc among Stanley's followers and produced intense suffering, and sometimes death by tetanus. Sometimes, however, death was more rapid, and one instance is given of death within one minute from a mere pin-hole wound. Mr. Stanley is not able to give the scientific names of the plants or animals from which these poisons are extracted, but states that one of a pitch-like consistency and color is made out of a species of arum; another is decocted from ants, which are crushed into a fine powder and mixed with palm-oil. The treatment found successful in combating the poison was to suck and wash out the wound and inject a strong solution of carbonate of ammonium, and to control the tetanic convulsions by hypodermic injections of morphine."—*British and Colonial Druggist.*

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be, creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Original Communications.

A CLINICAL STUDY OF FORTY-SEVEN CASES OF PARALYSIS AGITANS.*

By FREDERICK PETERSON, M. D.,

CHIEF OF CLINIC, NERVOUS DEPARTMENT, VANDERBILT CLINIC, AND LECTURER ON NERVOUS AND MENTAL DISEASE AT THE NEW YORK POLYCLINIC.

THIS study is based upon the careful observation of twenty-nine cases of paralysis agitans in Dr. Starr's department of the Vanderbilt clinic; six cases from the nervous department of the polyclinic in charge of Dr. Sachs, and five cases from my wards in the New York Hospital for Nervous Diseases on Blackwell's Island. Besides these, Dr. Starr has kindly furnished me the notes of seven additional cases from his private records. Only forty of the total number of cases, therefore, have been personally examined by me.

For the purpose of practical study and easy survey, I have grouped the facts adduced from the cases under separate small headings—ætiological, symptomatic, pathological, and therapeutic.

ÆTIOLOGY.

Age at Onset.—The period of life at which the tremor began may be seen from the following table:

AGE AT ONSET.	Males.	Females.	Total.
30 to 40	2	1	3
40 to 50	7	2	9
50 to 60	12	11	23
60 to 70	7	3	10
70 to 80	1	1	2
Total	29	18	47

In the majority, then, it developed between the ages of fifty and sixty, while forty-two of the forty-seven cases were between forty and sixty years of age at the onset, thus agreeing with the statistics of other observers.

Sex.—The fact that men are more frequently affected by this disease than women is borne out by my figures. Of the forty-seven cases, twenty-nine were males and eighteen females.

Heredity.—It is a moot question whether a hereditary taint plays any particularly important rôle in the development of paralysis agitans. In only two of these cases could any such factor be suspected. They were the cases of a brother and sister. In the former it is still mild in its manifestations, while in the sister the disorder has led to irremediable contractures in both hands and both feet and to such general rigidity that locomotion is almost impossible, and even speech difficult. At the same time this may have been an instance of a communicated functional disease, analogous to *folie à deux*, which is usually a communicated insanity, and to imitated chorea and to hysteria major. The sister had the disease for many years previously. The brother had become nervous through overwork, and had some intention tremor of his fingers when first seen by me. The paralysis agitans has developed in him under my observation, and there has always been constant anxiety upon his part lest he should be afflicted like his sister. Possibly his continual observation of her and comparison of his own symptoms have actually induced them in himself. Some support is given to this idea by the cases of a husband and wife who are also of the forty I have studied.

Mrs. M. is now fifty-seven years of age and has the typical symptoms of Parkinson's disease. The tremor began four years ago in her left hand. Mr. M. is sixty-seven years of age, and about a year ago noticed some tremor in his hands which may have been simply senile; but within two months last past a rhythmical tremor, precisely like his wife's, has appeared in his right hand. He has also been fearful of becoming a victim to shaking palsy.

Occupation.—All the patients were from the common walks of life, but a few of them followed pursuits in which they were especially subjected to exposure to extremes of heat or cold. Thus, one was a night-watchman, one a coachman, one a messenger, one an engineer, and one an out-of-door laborer, and one worked as a tobacconist in a damp basement for thirty years.

Exposure to Cold and Wet as a Cause.—In eight cases the immediate cause given for the tremor was working in the wet and cold. Two of these patients, both men, date the onset of the disease from the famous "blizzard" of March 14, 1888, when New York was snowed in to such an extent that all travel was suspended for a day or two, and several people were lost and frozen to death in the streets. These two men were both out in the storm, and the tremor followed almost immediately upon the exposure to the cold and the exertion required to reach their homes.

Moral Causes (worry, anxiety, grief, excitement, and fright).—One of my patients was an illicit distiller of whisky, and the disease appeared soon after his discovery and trial and the confiscation of all his property. In three cases domestic infelicity was an ætiological factor. One woman developed it during an anxious period of nursing a dying mother, and another during a period of worry over her drunken son. One woman gave as a cause a sudden fright. In one man the tremor appeared soon after great excitement incident to a religious discussion.

Traumatic Causes.—In one woman the tremor began in the right arm subsequently to a fall from a step-ladder, and in another it followed a fall down stairs. A beautiful example of trauma as an exciting cause was that of a man who at the age of fifty-two was driving a refractory horse. The horse ran away and threw him out upon his left shoulder. No immediate harm was done, but paralysis agitans soon became manifest, the tremor beginning in the left arm. Fright must have also had a share in its production.

Miscellaneous Causes.—In one case fever and ague of three months' duration immediately preceded the development of Parkinson's disease. In another, articular rheumatism in the left foot was antecedent to the development of tremor in that extremity. One case, examined very recent-

* Read before the New York Neurological Society, May 6, 1890. See also a study of twenty-two cases of paralysis agitans in Professor Starr's book *Familiar Forms of Nervous Disease*, 1890.

ly, has followed closely upon an attack of *la grippe*. Among causes given by other authors are to be mentioned gout by Lhirondel (*Thèse de Paris*, 1883), and typhoid fever by Berger.

Symptoms.

Tremor.—This is one of the most important symptoms of paralysis agitans, although, paradoxical as it may seem, a number of cases have been observed of true Parkinson's disease without the tremor. Thus, Charcot observed two such cases, Berger and Wienskowitz two, Buzzard one, Hardy one, Amidon one (*N. Y. Med. Record*, Nov. 24, 1883), and Beevor has lately described four (*Med. Soc. Proceed.*, 1889, vol. viii, p. 8). Rigidity, however, is always present when the tremor is wanting.

This symptom was present in all of the forty-seven cases. The extremities in which it first originated, as related by the patients, are tabulated as follows:

	Cases
Tremor began in right hand in	18
" " left hand in	20
" " left foot in	5
" " both hands (?) in	3
" " both feet (?) in	1
Total	47

The extent of the tremor at the time of examination may be gathered from the following:

	Cases
Tremor present in all four extremities of	12
" " all four extremities and head of	3
" " all four extremities and lips, tongue, and head of	3
" " both upper extremities of	4
" " both upper extremities and head of	2
" " both upper extremities and face of	1
" " both upper extremities and head and face of	1
" " both upper extremities and left lower of	3
" " both lower extremities and left upper of	2
" " left upper extremity only of	3
" " left upper and left lower extremities of	6
" " right upper extremity only of	3
" " right upper and right lower extremity of	4
Total	47

Charcot's statement that the head never takes part in the tremor, but is only moved by the contiguous movements of the upper extremities, has been proved to be unfounded in fact.* It will be observed that there was tremor of the head in nine of my forty-seven cases, and in all of these it was possible to determine the participation of the neck musculature in the tremor.

With the exception of the shivering from cold or terror, the tremor of paralysis agitans is almost the only one developed when the body is in a condition of rest. Almost all others belong to the class of intention tremors, or to such as are originated when the limbs are extended without support. Furthermore, the tremor varies greatly in extent and rate of rhythm at different times and even in different parts of the body of the same individual. We note in some cases that there may be a cessation of the tremor completely for an hour or two daily, or in others great diminution or increase for an indefinite period. Although usually an effort of the will can cause it to cease at least momentarily, yet occasionally it is uncontrollable. By means of an Edwards sphygmograph numerous tracings of tremors in various diseases have been taken by me at the Vanderbilt Clinic, some of which were made the subject of a short contribution on muscular tremor read before the American Neurological Association at Washington, September 20, 1888.* I determined the average rate of vibration of this tremor to be from 3·7 to 5·6 per second, agreeing with all other investigators (except Gowers), as will be seen from the following table:

Author.	PUBLICATION.	Rate to the second.
Marie	*Contrib. à l'étude*, etc.	5
Charcot	*Mal. du système nerv.*	4–5
Ewald	*Berl. klin. Woch.*, 1883, No. 32	5
Grashly	*Arch. für Psych.*, 1885	4·14–5·34
Huber	Virchow's *Arch.*, vol. 108, p. 45	3·43–5·57
Gowers	*Dis. of the Nerv. Syst.*, 1888, p. 1001.	4·8–7
Wolfenden & Williams	*Brit. Med. Jour.*, May 19, 1888	5·1
Peterson	*Jour. of Nerv. and Ment. Dis.*, Feb., 1889.	3·7–5·6

It is probable that all tremors are a modification of the rhythmic discharges of energy from the cortex, which, as is well known, take place at the rate of ten in a second. Consequently, when there are fewer to the second, it is because of the fusion of two or three impulses. The dicrotic character of the oscillations in paralysis agitans has been demonstrated by Wolfenden and Williams by means of specially constructed myographic apparatus.† Illustrations of the tremor of paralysis agitans taken from various portions of the body, and also a series of myograms from different diseases, are here inserted for comparison.

Rigidity.—This symptom was present in forty-one cases, although more marked in some than in others. In three it was absent and in three unnoted. As is well known, the rigor musculorum manifests itself in the extremities, trunk, neck, and face. The muscles of the eyes are extraordinarily seldom affected. Debove has reported cases where there was rigidity of the ocular muscles (*Le progrès médical*, 1878). In one case of mine the orbicularis oris was so inflexible that the patient had no control over it, and she driveled constantly. Rigidity of the lingual musculature was observed in a few cases, and probably a certain amount of stiffness of the muscles concerned in articulation and phonation accounts for the peculiarities of speech noted in some.

In two cases with a hemiplegic type of paralysis agitans affecting the left side the rigidity was limited with remarkable precision to the muscles of the left side of the head and neck, left arm and left leg, and even to the left sides of the tongue and orbicularis oris. There was no history or symptom of hemiplegia. We find commonly

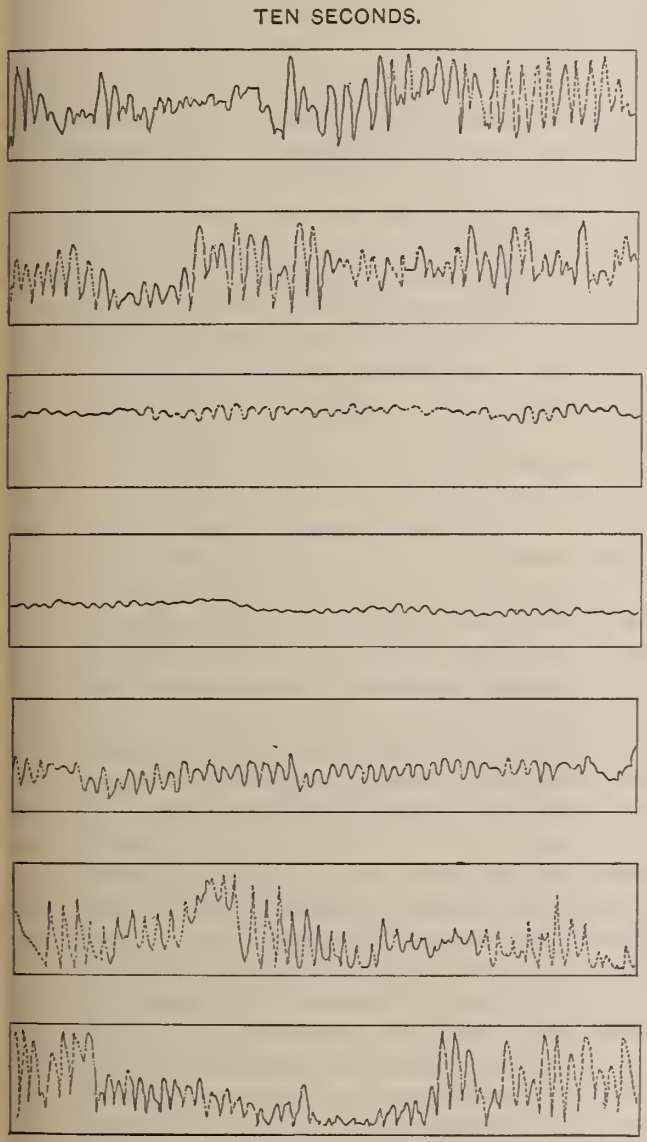
* The following are some of the authorities who have disproved Charcot's assumption: Oppolzer, *Spital Zeitung*, Nos. 17, 18, 1861. Clement, *Lyon médical*, No. 26, 1869. Jones, *British Med. Journal*, 1873. Westphal, *Charité Annalen*, iii. u. iv. Jahrg. Demange, *Revue d. méd.*, ii, 1882. Buzzard, *Clinical Lectures on Dis. of the Nerv. Syst.*, 1882. Huber, *loc. cit.* Gowers, *loc. cit.* (8 out of 37 cases).

* See *Journal of Nervous and Mental Disease*, February, 1889.

† *Loc. cit.*

loss of power or an actual paresis in connection with the rigidity of the muscles.

Contractures.—Over eighty per cent. of the cases presented the typical position of Parkinson's disease as figured



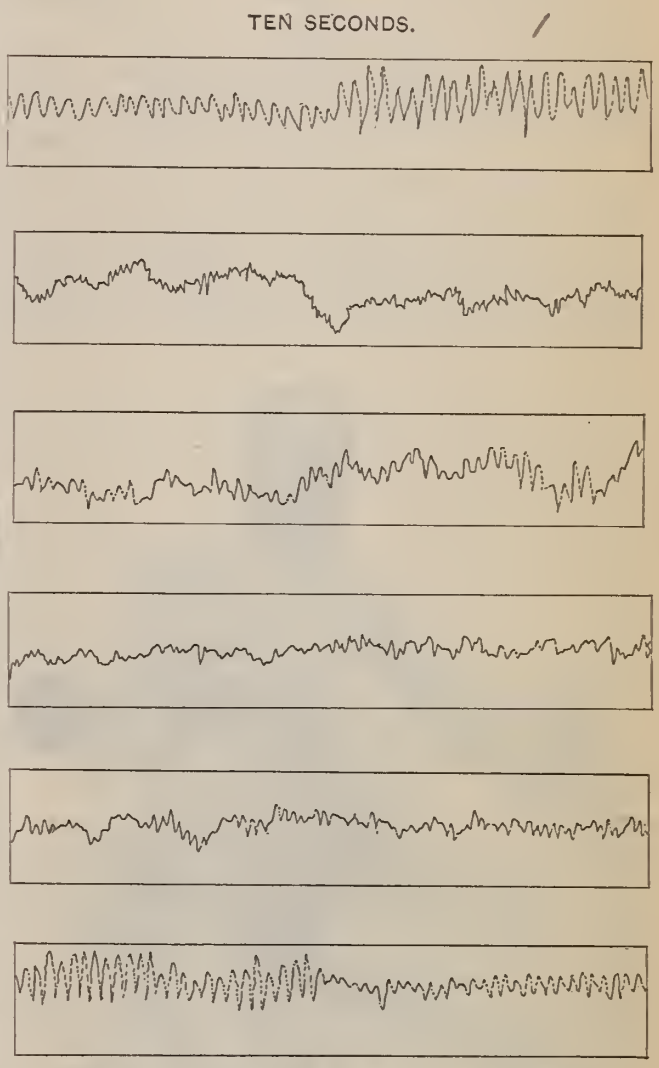
TREMOR OF PARALYSIS AGITANS.

1.	Tremor of extensors of carpus of right hand,	5·3 per second.
2.	" " " "	5·1 "
3.	Tremor of head while hands held a chair,	4·4 "
4.	" " " "	4·6 "
5.	Tremor of head, no effort with hands to keep steady,	4·8 "
6.	Tremor of Interossei,	4·5 "
7.	" "	4·9 "

in the text-books. The bowed head, flexed elbows and knees, and flexed metacarpo-phalangeal joints are to be looked upon as species of contractures. Often the flexors of the forearm were so contracted that complete extension could not be made, and almost always an attempt to stretch them was painful.

Two patients, both women, were completely helpless with the most advanced degree of contracture that I have ever seen in this disease. They both had double talipes equinovarus and absolute ankylosis of all the joints of the hands in the characteristic postures of fingers and wrists, but of an extremely exaggerated type. They could move their thighs when placed in a standing position, so that they could walk when supported by another; but it was impossible for them to turn in bed or rise from a chair.

Muscular Wasting.—It is not uncommon to observe some wasting of the muscles in cases of long standing, but this is not always apparent unless the disease is of the uni-



A COMPARATIVE SERIES OF MYOGRAMS OF VARIOUS TREMORS.

1.	Paralysis agitans,	4·7 per second.
2.	Morbus Basedowii,	11·7 "
3.	Multiple sclerosis,	5·4 "
4.	Hysterical tremor,	7·7 "
5.	Neurasthenic tremor,	7·4 "
6.	Delirium tremens,	5·6 "

lateral type. A patient now under my care at the New York Hospital for Nervous Diseases exhibits this phenomenon to a remarkable degree. R. B., aged sixty, admitted February 27, 1890, has for nine months past suffered from a typical tremor and a gradually increasing weakness and stiffness confined to the left side. It began in the hand and now involves the left face, arm, and leg. The middle and ring fingers are strongly contracted into the palm. There is also now some tremor in the right arm and leg. It is very marked in the tongue and lower facial muscles. There is a striking atrophy of the left arm and leg as com-

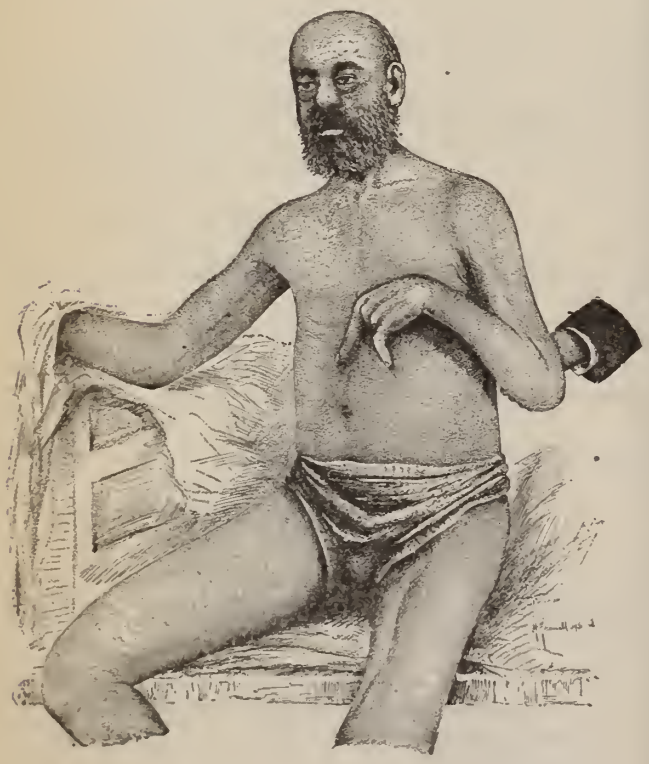
pared with the right extremities, but it is especially marked in the abductor and opponens pollicis, abductor indicis and minimi digiti, interossei, and adductors of the thigh on the left side. The measurements of the circumferences are as follows:

Showing the amount of wasting in a case of paralysis agitans where the disease was limited to the left side.

CIRCUMFERENCE OF—	Right.	Left.	Difference.
Arms: 18 cm. below shoulders.	25·5–23	22·5–20·5	2·5–3
Forearms: 15 cm. below elbows	21 –19	18 –16·5	2·5–3
Thighs: 15 cm. above patellæ.	37 –34·5	35·5–33	1·5
Legs: 15 cm. below patellæ..	29 –27	28 –26	1

The faradaic reaction in the wasted muscles was normal.

His rigidity was so great that he could not be photographed in good position, but the accompanying photograph shows the wasting and contractures in the elbow and fingers.



Propulsion, Retropulsion, Lateropulsion.—Fifteen cases presented no peculiarity of gait as evidenced by "running after the center of gravity." Propulsion, or festination, alone was observed in twelve, and retropulsion alone in three. Both propulsion and retropulsion were of frequent occurrence in nine cases, and lateropulsion remarked in but one. Anton Heimann, who reports in detail nineteen cases of Parkinson's disease in his exhaustive monograph (*Ueber Paralysis agitans*, Berlin, 1888), noted the occurrence of lateropulsion also in but one case. Gowers speaks of one. A tabular view of the relations of these phenomena of locomotion in forty cases where they were inquired into is here appended:

	Males.	Females.	Total.
Propulsion only	7	5	12
Retropulsion only	1	2	3
Both propulsion and retropulsion	5	4	9
Lateropulsion	1	..	1
No peculiarity of gait	9	6	15
Total	23	17	40

Tendon Reflexes.—In only nine cases were the knee, wrist, and elbow jerks exaggerated. In six they were hypertypical and in all the rest normal. The exaggeration was never so marked as in cases of organic disease of the cerebro-spinal segment of the motor tract, and indeed no greater than is commonly observed in people of advanced age, where we ordinarily expect an increase of the deep reflexes. In one of Dr. Starr's private cases where tremor was limited to the left hand, the left knee-jerk was exaggerated and the right absent. Ankle clonus was not obtained in any.

Electrical Changes.—In one case of eight years' standing with the disease limited wholly to the left side I was enabled to demonstrate conclusively diminished neuro-muscular contractility to faradism upon the affected side. This corroborates Benedikt, who noted many years ago a diminution of electrical irritability in affected extremities of old cases. His further statement that neuro-muscular contractility is markedly increased in such parts in recent cases I had no opportunity to confirm.

The Voice and Speech.—Buzzard, in a clinical lecture on shaking palsy (*Brain*, January, 1880), called attention to the high pitch and piping quality of voice in some cases of the disease, and other authors have mentioned the occasional peculiarity of a sort of halting ejaculation of words. There were distinctive characteristics of articulation and phonation in no less than thirteen of the forty-seven cases. There is probably no question that these changes depend almost wholly upon a certain amount of rigidity in muscles concerned in speech and vocalization. The especial features I have noted in the thirteen cases are, firstly, a condition of monotonia, as though there were difficulty in adjusting the vocal cords for the purposes of varying the pitch; secondly, a high pitch and piping quality of tone, which may possibly depend upon a certain minute degree of contracture in the crico-thyreoid, posterior crico-arytænoid, and internal thyreo-arytænoid muscles. A laryngologist might make an interesting study of vocalization in this disease. Thirdly, there is often what has been well termed a species of festination in speech. There is some difficulty in starting a sentence, a hesitation upon the first word, but, that word having been articulated, the patient rapidly repeats the whole sentence if a short one; if it be long, he pronounces quickly five or six words, and then stops to readjust his muscles apparently before ejaculating another series. There are points of analogy between the festination of gait and that of speech.

Thermal Paræsthesia.—An excessive feeling of heat over the whole body, or more rarely in limited areas, has been mentioned by various writers as frequent in Parkinson's

disease. Charcot found no alteration of temperature in such cases, while a later observer, Berger, maintained that while the general temperature was normal there might be a marked peripheral increase. This subjective sensation of heat I noted in seven of my cases—in six general, in one limited to the abdominal surface. This last patient, a man (C. D.) aged sixty, had continually such a feeling of intense heat over his abdomen that he was constrained to keep constantly lifting his clothing from that surface. I placed an Immisch thermometer carefully covered upon his abdomen for seven minutes, and an ordinary clinical thermometer under his tongue for the same length of time simultaneously. The abdominal surface had a temperature of 97°, the mouth 98·5°.

At the summer meeting of the French Society for the Progress of Sciences (*Ctrlbl. für Nervenheilk.*, Nov. 15, 1889), Mossé, of Montpellier, reported his observations upon this matter in two cases of the disease. He found no actual increase of peripheral temperature. In one case the thermal paræsthesia was coincident with broad patches of superficial redness on the back of the hands and under surfaces of the forearms. He regards this sensation of heat, as well as the exanthema and œdema sometimes observed in shaking palsy, as phenomena due to disturbance in vaso-motor centers.

Paræsthesia of Cold.—This symptom was present in five of the forty-seven cases. One woman (R. M.), aged sixty-five, whose tremor began in the left arm, has always had a subjective sensation of cold in that arm. A man (T. F.), aged sixty-eight, who has the disease confined to both arms, complains of a feeling of great cold in those extremities. I observed no particular coldness of the arms upon examination.

Miscellaneous Paræsthesiæ.—Patients often complain of numbness and prickling, sometimes of rheumatoid or neuralgic pains in the extremities. One man had shooting pains in his legs; another a dull, aching pain in the three extremities affected; another numbness in the hands and soles of the feet; another much pain in his two arms, which were the seat of the disease; still another had burning pains in his limbs. Two women also complained of pains in the affected members. Anæsthesia has never been noted.

Hyperidrosis.—This symptom, if it is present, is, as a rule, associated with thermal paræsthesia, and in all likelihood depends upon the vascular relaxation which seems to give rise to the feeling of heat. Hyperidrosis existed in but four of the forty-seven cases, and in these the perspiration was very profuse and the sensation of heat extreme.

Restlessness.—Very many cases have a feeling of general discomfort, a species of *anxietas tibiarum*, only distributed over the whole body. It makes them exceedingly restless, especially at night. Seven of the forty-seven patients made particular mention of this trying symptom.

Tachycardia.—Although Marie and Azonlay (*Progrès méd.*, 1885, No. 49) speak of the frequency of this symptom in cases of paralysis agitans, it existed in but one of the cases here collected, a man, aged fifty-four, with a pulse of 120.

Mental State.—In many cases diminished intelligence or veritable psychoses have been described in connection with Parkinson's disease, but there was only one thus affected out of my forty-seven cases. The exception was a woman who developed first an acutely melancholic condition with auditory and visual hallucinations, and is now considerably demented. Many patients are more or less depressed by their hopeless and uncomfortable state, and in many there are present loss of memory and mental weakness which should be considered merely senile in character.

Pathology.

I have had no autopsy in any of these cases. Post-mortem examination has thus far failed to discover any lesion to account for the disease. It is doubtless one of those so-called "functional" diseases of the motor areas of the cortex due to nutritive changes of a degenerative character. The weakness, clonic movements of the muscles, rigidity, contractures, and unilateral development of the disease point to the cortex as its seat. The postures of the hands and feet are similar to those of hemiplegia, epilepsy, and tetany. The unilateral development is like that of monoplegia, hemiplegia, and chorea. Yet, though the rigidity is also like that of the paralyses of cerebral origin, it is difficult to explain the absence of spasticity, the deep reflexes being usually normal. The vaso-motor symptoms, giving rise to sensations of heat or cold, unilateral sweating, general hyperidrosis, and sometimes œdema and the rheumatoid pains, are not easily explicable on any acceptable hypothesis. But it is possible that changes in the peripheral nerves may some time be discovered, which would account for some of these peripheral disturbances, and perhaps also for the more than ordinary wasting occasionally observed in these cases.

Treatment.

The exact pathology of the disease not yet having been determined, all treatment has thus far been more or less symptomatic, and directed in particular toward diminishing the tremor. The following is a list of some of the more important therapeutic agents that have been employed, and if they have no other interest, they have at least some pessimistic significance: Potassium bromide and iodide, tincture of veratrum, veratrin (Féris), chloride of barium (Brown-Séquard), carbonate of iron (Elliotson), strychnine (Trousseau), ergotine, Calabar bean (Ogle), chloral hydrate, opium, morphine (Heimann), atropine, belladonna, gelsemium, curare, hyoscyamine (Charcot), Fowler's solution (Eulenburg, hypodermically), coniine (Berger), and eserine (Riess).

Hydrobromide of hyoscine was first used in paralysis agitans by Dr. Langdon, of the Hudson River State Hospital, and myself. In a paper on the employment of this drug in cases of insanity, published in the *Medical Record* in 1885, we called attention to a case of paralysis agitans in which the tremor ceased entirely while the patient was under its influence.* In a discussion upon the treatment of this

* Hydrobromate of Hyoscine. Its Use in Forty-eight Cases of Insanity and Epilepsy. By Frederick Peterson, M. D., and Charles H. Langdon, M. D. Case XXVIII, *Medical Record*, Sept. 19, 1885.

disease before this society about a year and a half ago I also spoke of the efficacy of this drug in diminishing the tremor.

Heimann is an enthusiast as regards the use of morphine in these cases. He says (*loc. cit.*): "It is the only remedy which can, for at least a short time, make the patient comfortable."

Recognizing the value of opiates for overcoming the feelings of discomfort and restlessness which serve to make the lives of patients with Parkinson's disease continually miserable, I have latterly employed codeine with considerable benefit, especially when combined in the form of a pill with hydrobromide of hyoscine (codeine, gr. ss.–ij; hyoscine hydrobromide, gr. $\frac{1}{100}$), and administered twice or thrice daily. While codeine possesses many of the useful attributes of morphine, it is less deleterious in its influence upon the system.

A CASE OF UNILATERAL PARALYSIS OF THE ABDUCTORS OF THE LARYNX,

THE RESULT OF AN ATTACK OF BULBAR DISEASE WITH UNUSUAL SYMPTOMS, AND WHICH WAS APPARENTLY CAUSED BY SUPPURATIVE DISEASE OF THE ANTRUM.*

By F. H. BOSWORTH, M. D.

The interesting series of experiments on the functions of the larynx made by Hooper (*Trans. of the Amer. Laryng. Assoc.*, 1885, p. 9; 1886, p. 22; 1887, p. 41; 1888, p. 163), F. Donaldson, Jr. (*Trans. of the Amer. Laryng. Assoc.*, 1886, p. 213; 1887, p. 80), Semon and Horsley (*British Med. Jour.*, 1886, August 28th and September 4th. pp. 405 and 445), Krause (*Arch. f. Anat. und Physiol., phys. Abtheil*, 1884), Onodi (*Ctrlbl. für d. med. Wissenschaft.*, 1889, vol. xxvii, pp. 258 and 289), and Simanowski (*Geschen. klin. Gaz.*, No. 26, 1887) have rendered the question of laryngeal paralyses one of no small interest. As contributing somewhat to our knowledge of the subject from a clinical point of view, I bring before you the following case:

J. W. M., a member of the judiciary in one of our Western States, consulted me on March 27, 1890, with the following history:

In August, 1889, he suffered with an ulcerated second molar tooth, which gave rise to an attack of facial neuralgia, involving the whole of the left side of the face. The tooth was extracted, with relief to the pain, but an offensive purulent discharge, which had set in from the left nasal passage, coincident with the attack of toothache, persisted. He felt and thought this was an accumulation in the antrum. This latter system has continued ever since—an ill-smelling, yellowish discharge, which passes into the fauces and is discharged through the nostril. When lying down, the flow of pus into the larynx is a source of especial annoyance. He is a man of large physique, and has always enjoyed perfect health.

On November 20th he retired in his usual health. He was awakened suddenly in the early morning hours by something happening which he could not describe. On attempting to rise in bed, he found that he fell over to the right side. There was considerable nausea, and, to allay this, he attempted to drink a little water, but this he found to be an absolute impossibility. He got out of bed with considerable difficulty and got down stairs, but he found himself walking with very great effort and unconsciously turning to the right. He was also very dizzy, and the nausea continued. On further questioning himself as to his symptoms, he found that he was partially paralyzed as to motion over the whole of the right side from the crown of the head to the soles of the feet. On the left side there was paralysis of sensation to this extent: that while the tactile sense was not destroyed, his appreciation of heat and cold was absolutely gone. There was also some slight dyspnœa, although his voice was unimpaired as far as he knew, except that the vocal tones were somewhat peculiar. This latter symptom, of course, was due to paralysis of the palate.

There was no facial paralysis as far as he knew—that is, the face was not drawn, yet it felt heavy and stiff over the right side. There was also some impairment of sight, in that, as he expressed it, the eyes did not focus well. He could neither sneeze nor cough, although he could clear his throat with some little difficulty. The tongue was protruded slightly to the right side. Articulation was not impaired. The sense of taste was notably impaired on the left side of the tongue and the whole of the fauces. As he expressed it, the loss of sensation of taste on the left side extended down to his stomach. He declined to consider himself a sick man and kept about the house, although it was no small effort to move. The power of deglutition was lost for two days, but he commenced to swallow on the third day. This, however, was accomplished but slowly for some weeks. The motor impairment gradually disappeared, and on the twelfth day he walked down the street, though still with some effort. According to his own story, the impairment of motion lasted only two months, although at the time of his visit to my office, four months after, I could detect still some evidence of motor weakness. While this feature of his paresis improved rapidly, the sensory paresis of the left side seemed to improve quite slowly, and at the end of four months there was still a notable failure to appreciate the sensations of heat and cold.

When I first saw this patient he consulted me on account of his antrum disease, and he seemed to think that all his other symptoms had completely disappeared, and really described them to me as a curious experience which had happened to him some months before. I found him to be a man in almost perfect health, in whom a close examination failed to reveal any departure from the normal condition, with the exception of the symptoms above noted of slight sensory paresis of the left side. He went through the ordinary muscular tests of spinal and bulbar disease without revealing any impairment of power. There were the characteristic symptoms of disease of the left antrum, and this was successfully operated upon by opening the antrum through the alveolus. A large amount of pus was discharged and a Bordenave tube inserted.

An examination of the larynx showed the right cord lying motionless in the median line—in other words, there was complete paralysis of abduction of the right vocal cord.

It would have been interesting to have noted in this case whether there was an anæsthetic condition of the mucous membrane of the larynx. This, however, was not elicited, owing to a somewhat irritable condition of the fauces.

The first question that arises here is as to the cause of the bulbar disease and its possible connection with the suppurative disease of the antrum. This man, as I have said, was in the enjoyment of perfect health, and there was no

* Read before the American Laryngological Association at its twelfth annual congress.

obvious physical trouble which should have led to the development of bulbar disease other than the suppurating process in the antrum.

Dr. M. A. Starr, who saw this case with me, was disposed to agree with me in the idea that there was a thrombosis of one of the small arteries of the medulla, and that this thrombosis led to some meningeal disturbance extending to the cerebellum, which would account for the loss of co-ordination, with the motor and sensory impairment which characterized the early days of his attack.

The rapid disappearance of symptoms can be accounted for by the early re-establishment of the circulation. I think, without question, this patient had an attack of bulbar disease, in which the symptoms disappeared with unusual rapidity, and at the end of four months the only condition which remained was right abductor paralysis. This seems to have become permanent. The case, therefore, is interesting as one of bulbar disease, due probably to a suppurating process in the antrum of Highmore. It is further interesting as lending weight to the proclivity theory of Semon (*Arch. of Laryngology*, vol. ii, p. 197), and yet it seems to me quite clear that in this case the laryngeal paralysis was the result of a disease of the nerve centers alone. The ganglionic center which presides over the respiratory movements of one side of the larynx lay in the area of distribution of the artery which was occluded. The motor center of the larynx in the medulla has not as yet been practically isolated. The diseased process in my patient, however, seems to have isolated the ganglion which presides over the respiratory function of one side of the larynx whose fibers pass through the recurrent laryngeal nerve; and yet it seems to me there is no evidence whatever that any other fibers of the recurrent laryngeal nerve were in any way disturbed.

Why, therefore, does the paralysis of abduction become permanent, while this patient recovers both motion and sensation of the other parts involved? There are but two answers to this: either the ganglion presiding over the respiratory function of one side of the larynx is permanently destroyed, or there is an essential proclivity on the part of the abductor muscles to become the seat of paralysis. This undoubtedly exists, and is shown clinically by the fact that when their function is abolished they become the seat of a rapid degenerative process, under which they lose their power of responding to the stimulus of motor innervation.

This latter view, as before stated, seems to be largely established, not only by clinical observation, but is prominently the teaching of the very elaborate series of physiological experiments alluded to at the commencement of this paper.

As I understand Semon's article on the proclivity theory, this condition lies in the fibers of the recurrent laryngeal nerves rather than in the muscles. It certainly seems to me that the weight of evidence is in favor of the view that this proclivity manifests itself in the muscular fibers of the posticus muscle rather than in the nerve. The point is certainly an interesting one, but is scarcely to be entered upon at length here. Another interesting point in this connection is as regarding the question of intrinsic and extrinsic paralysis. I have reported here a case of paralysis of undoubted central origin.

About the time that this patient came under observation another gentleman called on me with the following history:

J. W. C., aged fifty-six, broker. He was of fine physique and apparently in the enjoyment of perfect health, and yet was one who was always exceedingly nervous and sensitive about his own physical health. About six weeks before he had consulted a physician, who, as I understood, made a diagnosis of recurrent laryngeal paralysis due to aneurysm. This diagnosis so completely unnerved him that he was practically confined to his house in a state of nervous prostration for from four to five weeks. As soon as he was able he came to New York. On examination, I found his left vocal cord moving in about one half its normal excursion; in phonation it was approximated nearly to the median line, while in inspiration it was abducted to perhaps a little more than one half the normal extent. Its movement was somewhat sluggish, but there was unquestionable movement both in the cord and in the arytenoid cartilage.

I made an examination and found nothing abnormal in the thorax. This patient, at my suggestion, consulted Dr. Loomis, who pronounced him absolutely sound, as to both heart and lungs. My own diagnosis already made was that of partial ankylosis of the crico-arytænoid joint, due probably to the rheumatic habit. The diagnosis was given with absolute positiveness and the patient returned to his home reassured, and, as far as I know, has had no return of his neurasthenic symptoms. The local symptoms in the fauces had never been other than of a mild form of naso-pharyngeal catarrh.

Here was a case pronounced one of paralysis by a very competent observer, and yet, in my opinion, was one which should not be regarded as either intrinsic, myopathic, or any other form of paralysis.

I make this assertion deferentially and not polemically, but mainly on the ground that it seems to me our nomenclature will be very greatly cleared up by relegating a very large proportion of our cases of so-called intrinsic paralysis to a totally different classification, and confining the word "paralysis" to those cases which are due to a diseased condition either of the nerve trunk or of the ganglionic centers.

Coming back now to the question of central paralyses, I find a number of cases of recurrent laryngeal paralysis, involving one or both sides, reported by the following observers as due to bulbar disease: In a case reported by Hughlings Jackson (*Lond. Hosp. Reports*, 1864, vol. i, p. 361) there was paralysis of the right recurrent laryngeal. In a second case by the same author (*loc. cit.*, p. 368) there was paralysis of both cords. In a third case by the same observer (*Lond. Hosp. Reports*, 1867, vol. iv, p. 314) there was paralysis of the left cord. In a fourth case by this writer (*op. cit.*, p. 318) there was paralysis of the right recurrent laryngeal. In a case reported by Proust, cited by Hallopeau (*Des paralyses bulbaires*, Paris, 1875, history 23), there was paralysis of both cords. In a case reported by Senator (*Arch. f. Psychiatrie*, vol. xi) there was paralysis of both cords. Eisenlohr (*Deut. med. Woch.*, 1886, p. 363, also *Arch. f. Psych.*, 1887 and 1888, vol. xix, p. 314) reports

three cases, in two of which there was recurrent paralysis on both sides, while in the third there was recurrent paralysis of the left side. Sokaloff also (*Deut. Arch. für klin. Med.*, vol. xli, p. 458) reports a case of left recurrent paralysis.

All these cases resulted in a fatal termination, and post-mortem examinations were made in all, with the exception of Hughlings Jackson's first two cases. The lesion in every case was found to be extensive destruction of the medulla, involving the pyramids, olivary bodies, restiform bodies, floor of the fourth ventricle, etc. In other words, we find here a series of cases in which the bulbar disease was of such an extensive character as to produce a fatal termination; and, furthermore, that where the local disease was so extensive it resulted in the completest possible paralysis of the muscles of the larynx—viz., recurrent laryngeal paralysis of one or both sides. In the third of Eisenlohr's cases, above alluded to, the post-mortem examination showed the left recurrent nerve involved in a thickened pleura, which might possibly have been considered as causing the laryngeal paralysis; yet there was also an extensive degeneration of the medulla, and, furthermore, the laryngeal symptoms antedated the pulmonary disease by about two years.

In addition to the foregoing, Oppenheim (*Berl. klin. Woch.*, 1886, No. 40, p. 675) and Kehler (*Zeit. f. Heilk.*, 1881, p. 440) report cases of recurrent laryngeal paralysis, the former involving the right cord and the latter the left, as occurring in connection with locomotor ataxia. Wegner (*Annual of the Universal Med. Sciences*, vol. i, p. 89) takes the ground that the laryngeal paralysis in cases of tabes usually takes the form of paralysis of the abductor muscles, citing two of his own, and making a compilation of a number of other instances. This certainly is not the rule, in view of the cases just instanced, although, in addition to Wegner's, we find Krause (*Berl. klin. Woch.*, 1886, No. 20, p. 651), Ross (*Brain*, London, 1888), and Saundby (*Birming. Med. Review*, December, 1886) reporting cases of tabes in which there was bilateral abductor paralysis; while, in a case reported by Semon (*loc. cit.*) of double abductor paralysis, the patient subsequently developed tabes. In a case of tabes reported by myself (Laryngeal and Pharyngeal Paralyses, *Journal of Nervous and Mental Diseases*, 1889, Case I) there was bilateral paralysis of the laryngeal abductors. Hubbard (*Toledo Med. and Surg. Reporter*, 1889, vol. ii, p. 576) reports a case of tabes in which there was recurrent laryngeal paralysis of the left side.

Of course there is no special clinical deduction from the laryngeal paralysis in locomotor ataxia other than that the extent and direction which the sclerosis takes dominate the form and extent of laryngeal paralysis.

In addition to the foregoing, I find cases of double abductor paralysis reported by Ollivier d'Angers, cited by Gottstein (*Die Krank. des Kehlkopfes*, 1888, p. 309), Krause (*Neurol. Centralblatt*, 1885, p. 543), and Penzoldt (von Ziemssen's *Cyclop.*, vol. vii, p. 962), in all of which the autopsy showed extensive lesion of the medulla, while in a case reported by Smith (*Brit. Med. Jour.*, July 13, 1878) there was evident central lesion, although no autopsy was made.

This would seem rather a small proportion of cases of bilateral abductor paralysis in which the central lesion was established, and yet it must be borne in mind that a very large proportion of cases of this disease have clearly been traced to local morbid processes, while in others the mere insertion of a tube has so far prolonged life that the origin of the disease has remained obscure.

As regards unilateral paralysis of the abductor muscle, the number of cases reported in literature is not large; moreover, this affection gives rise to comparatively trivial symptoms, and undoubtedly in many cases escapes observation. Of this form of unilateral paralysis of abduction in the larynx cases have been reported by Gerhardt, cited by Gottstein (*op. cit.*, p. 310), McBride, cited by Gottstein (p. 311), Nothnagel (*Wien. med. Blätter*, 1884, No. 9), Martius (*Charité Annalen*, 1889, vol. xiv, p. 315), and Delavan (*Med. Record*, Feb. 14, 1885, p. 178). In all of these cases an autopsy revealed lesion of the medulla or base of the brain. In Delavan's case it should be stated that the form of paralysis is reported as complete paralysis, the cord lying in the median line, which seems to leave it somewhat uncertain whether this is abductor or recurrent laryngeal paralysis. In a case reported by Wright (*N. Y. Med. Jour.*, 1889, vol. l, p. 345) the observer considered the disease of central origin, although no autopsy was made.

From this category there is omitted quite a number of cases in which the disease is attributed to local causes.

The object of my paper is fulfilled, therefore, in the report of the case which is the text of my remarks, and the further suggestion that we have completed our duty in no case of laryngeal paralysis unless we have either thoroughly eliminated or established the question of a central lesion as the source of the morbid condition. In other words, I am disposed to think that a central lesion is responsible for a genuine paralysis of the vocal cords in a somewhat larger proportion of cases than is usually believed.

26 West Forty-sixth Street.

A MODIFIED ALEXANDER-ADAMS OPERATION.*

By GEORGE M. EDEBOHLS, A. M., M. D.,
GYNÆCOLOGIST TO ST. FRANCIS HOSPITAL, NEW YORK.

The operation for shortening the round ligaments has established itself in the favor of comparatively few gynæcologists. This I believe to be due in very great part to the difficult and unsatisfactory technique of the operation as usually practiced, leading to disappointment and mortification and rendering it unpopular with operators.

During my earlier experience with the operation, embracing five cases, I shared the general unfavorable impressions, and was on the point of practically abandoning the operation in favor of ventro-fixation of the uterus in all cases of retroflexion and version where the symptoms and the failure of milder methods to relieve called for operative interference.

* Read before the Gynæcological Section of the Tenth International Medical Congress.

In a paper entitled Aus der gynäkologischen Abtheilung des St. Francis Hospitals in New York: Die Laparotomien des Jahres 1889,* I reported four hysterorrhaphies, of which three were performed for retroversion, one for retroflexion of the uterus. All of the patients were seen between six and twelve months after operation, and remained completely relieved of their former symptoms. In all, the uterus remained in anteversion. I quote from the paper:

Notwithstanding these favorable results, I shall in the future perform laparotomy for ventro-fixation of the uterus only in case the latter be adherent, or when other intra-abdominal conditions calling for operation complicate retroversion of the non-adherent uterus. The hysterorrhaphies just described were performed at a period when I was dissatisfied with the Alexander-Adams operation for shortening the round ligaments. This dissatisfaction was grounded chiefly on the difficulty of really shortening the ligaments, when found, in their intra-abdominal course. Since December, 1889, I have performed the operation for shortening the round ligaments eight (at present thirteen) times after a modification of my own, which I intend shortly to publish. In every case I easily succeeded in shortening the ligaments from three to four inches in their intra-abdominal course. The immediate results have been perfectly satisfactory; the final results remain to be tested by time. In case the good results prove permanent, I shall probably never again perform laparotomy for uncomplicated retroversion of the uterus, but shall, in such cases, resort to shortening of the round ligaments, or perhaps to a modification of the operation of vaginal ligature after Schuecking.

This quotation defines my present attitude, which I have found no occasion to change since writing the foregoing. In the latter part of 1889, as a result of some thought relating to the difficulties to be overcome and of study upon the cadaver, I elaborated for myself a modification of the technique of Alexander's operation. This I have since practiced in thirteen cases—seven times for retroversion or retroflexion, and six times for prolapse. These cases I have herewith tabulated, as likewise, for purposes of comparison, five cases in which I operated after the usual method. These eighteen cases include my entire experience in the operation of shortening the round ligaments. In all of the thirteen cases an immediate anatomical success was achieved. The retroverted uterus was brought into and held in normal anteversion; the prolapsed uterus, with the added aid of plastic operations performed at the same sitting, was sustained at its proper level in the pelvis.

About the permanent results it is as yet too early to speak. I have seen all of the patients at greater or less intervals since the operation, and thus far know of no case where the uterus has again become prolapsed or retroverted. Up to the time of my latest knowledge, an anatomical and a therapeutical success has been the result in every case. I shall on a future occasion report the final results as far as I may be able to ascertain them. The present paper is concerned chiefly with the technique of the operation which I shall now attempt to describe.

On the day preceding operation the patient receives a purgative, a pubic and vulvar shave, and a full bath. After being anæsthetized and placed upon the table, the site of operation and the surrounding parts are thoroughly cleansed with soap or mollin and water, irrigated with bichloride solution (1 to 3,000), dried, washed with ether, and again irrigated with the sublimate solution.

The spine of the pubes is located by the index finger. The incision begins just above it, over the site of the external abdominal ring, extending upward and outward, parallel to Poupart's ligament, for two inches and a half to three inches, according to the amount of adipose tissue. The adipose tissue is divided by clean cuts and without the aid of retractors until the glistening aponeurosis of the external oblique is laid bare. In the use of retractors there is danger of drawing too much upon one side or other of the wound and of dislocating its center, so that after cutting through the adipose tissue we may find ourselves upon the muscular aponeurosis at quite a distance from the external ring.

If there is much subcutaneous fat, it is advisable, while cutting through it, occasionally to feel for the spine of the pubes, so that the inner and lower end of the incision may bear directly down upon it. After exposing the fibers of the external oblique, the external abdominal ring, its pillars, and the intercolumnar fibers are readily distinguished.

Up to this stage the operation is identical with the one usually practiced; here the divergence begins. A grooved director is inserted into the external ring, just beneath its outer and upper margin. It is advanced along the inguinal canal, hugging closely its anterior wall, to a point opposite the internal ring. The anterior wall of the canal, along its whole length, is now divided on the director, observing care to cut as nearly as possible in the exact direction of the course of the aponeurotic fibers. The internal ring is gently felt for but not dilated, and sometimes the ligament can be distinctly felt emerging therefrom. Generally, however, it is not easy to be sure of feeling the ligament. A blunt hook is next passed down to the ring and its point made to sweep across the bottom of the wound from above and within along the posterior and inferior walls of the canal. The ligament is found in the inferior and outer part of the canal nestling close behind Poupart's ligament. It is brought out by the hook and liberated from its cellular attachments. The fibers of insertion into the canal are likewise separated from the walls of the latter. It will be found that the ligament, at its emergence from the internal ring, constitutes a well-marked, oval, strong band of fibers; that it immediately begins to spread out and attenuates rapidly as it proceeds inward and downward in the direction of the external ring.

The only difficulty in performing the operation is likely to be encountered here. If the ligament is picked up in the canal at a distance from the internal ring, it fails to present its peculiar ligamentous sheen, owing to its separation into fibers for insertion into the walls of the canal. The operator has the ligament upon his hook, but fails to recognize it. From its resemblance to muscular fibers he is liable to mistake it for the latter. If the seized bundle, however, is made tense by traction, it can be traced by the finger directly to the internal ring. Recollecting that the

* *New Yorker medizinische Monatsschrift*, May, 1890.

canal contains nothing but the ligament and the accompanying small ilio-inguinal nerve, the operator draws confidently upon the seized tissues and finds the round ligament, *in propria forma*, emerging with its peritoneal investment.

The broad ligament covering the round ligament is drawn out in the form of an inverted funnel. With one hand pulling on the round ligament in a direction at right angles to the plane of the aperture of the ring, two fingers of the other hand strip or peel back the peritonæum of the broad ligament from the round ligament, until three to four inches of the latter have been pulled out and bared. In doing this the reflection of the peritonæum should be distinctly kept in view. It is easily recognized as a white line running transversely across the round ligament, anteriorly and posteriorly, and all but meeting at the sides.

In three of the twenty-six ligaments thus treated, I have torn and opened the peritonæum in stripping it back. The resultant little holes gave no trouble. By spending a little time over the work, and stripping the peritonæum back gently and slowly, this accident can be avoided.

The wound is now protected with bichloride gauze and the operation performed in the same manner on the opposite side. The next step in the operation consists in stitching the drawn-out parts of the shortened round ligaments securely in the inguinal canal. The ligament is pulled out as far as it will go. I have never failed to draw it out three inches, nor ever secured a shortening of more than four inches.

One who has done the operation in the usual manner, drawing upon the ligament at the external ring with fear and trembling lest it at any moment break, will be agreeably surprised at the firm traction which can be exerted upon it at the internal ring without the sensation of impending stretching or rupture. Of the twenty-six ligaments thus drawn out, not one has ruptured, although in several instances they were so slender in structure that from my previous experience I felt certain the risk of tearing at the external ring would have been considerable.

The drawn-out ligament, still attached at the pubes, is now handed to the assistant, who, by means of the blunt hook, exerts sufficient traction to hold it taut.

This traction is made in the direction of the opened canal; so that a portion of the ligament which, previous to operation, was situated within the abdominal cavity, now occupies the space along the course of the canal formerly filled by the extra-abdominal portion of the ligament. In this situation it is secured by sutures of silk-worm gut passed in the following manner: The first suture traverses the wound at the level of the internal ring. It is introduced through one lip of the wound, embracing skin, superficial fascia, and the aponeurosis of the external oblique, into the inguinal canal. Here the taut ligament, as it emerges at the internal ring, is pierced transversely by the needle, which then traverses the other lip of the wound, penetrating in succession the cut fascia of the external oblique, the subcutaneous fat, and the skin.

Although very partial to the Hagedorn needle in most of my operative work, I here prefer the ordinary surgical needle curved on the flat. The Hagedorn, in traversing the ligament, cuts the longitudinal fibers, which the ordinary needle merely crowds between and separates.

Three to five sutures are passed in a similar manner through all the tissues on either side of the wound, into and across the canal, in their course through the latter piercing the ligament. These sutures, when tied upon the skin, close the opening in the anterior wall of the canal by bringing into juxtaposition the divided edges of the fibrous aponeurosis of the external oblique, as well as of the more superficial structures, while at the same time they moor the shortened ligaments safely inside of the canal, where they properly belong.

The operation is completed by cutting away the excess of ligament projecting beyond the lower angle of the wound. Drainage is effected by three or four strands of silk-worm gut running along the bottom of the wound along its entire course and emerging at either end. I take care that these silk-worm gut drains reach into the inguinal canal at one point by passing them beneath the deepest portion of one of the wound sutures.

I consider this matter of drainage very important, as considerable serum is apt to be effused. If no vent be given to it externally, it may burrow along the tissue planes in various directions and even suppurate. Indeed, this happened in two among my first cases in which I endeavored to dispense altogether with drainage in any form and closed the wound tightly. Pus formed and burrowed in various directions between the subcutaneous fat and the fascia of the external oblique, and even through the internal ring into the subperitoneal areolar tissue, necessitating free incisions and secondary drainage of these parts. It is but fair to state that both of these cases were operated upon during the height of the epidemic of "la grippe," and both were attacked by the disease after operation. The convalescence in both cases was tedious, though the anatomical success of the operation was fortunately not impaired.

Although in two of the first six cases I obtained primary union without the employment of drainage, the experience in the other four led me to adopt drainage systematically in all of my subsequent cases. An attempt was first made with rubber tubing, then with catgut, and finally, and with the most completely satisfactory results, with silk-worm gut. The smooth surfaces of the latter act as excellent conveyers outward of the pent-up fluids. On their withdrawal the tissues come together, closing and immediately obliterating their tracks. The wounds are dressed with pads of bichloride gauze laid across the lower part of the abdomen and kept in place by a double spica bandage. This latter is securely pinned, and, unless wound complications occur, the dressing is allowed to remain undisturbed for nine to twelve days. At the end of this time the sutures and the silk-worm gut drains are removed and the wound is redressed.

As to support of the uterus after operation, I have designedly avoided it, as far as possible. One patient with retroflexion wore a pessary for a month after operation. In the other cases of retroversion the uterus was sustained for two or three days by a tampon of iodoform gauze placed in the vagina on the completion of operation. Whenever a

plastic operation upon the vagina or perinæum was simultaneously performed—*i. e.*, in all cases of prolapse and in some of version—absolutely no support of the uterus after operation was practiced. The round ligaments were thus severely tested as to the security of their new anchorages and as to their ability to sustain the uterus in normal position. They successfully stood the test in every case.

I believe, however, with Alexander, that in every case where the operation is performed for retroflexion a glass intra-uterine stem should be worn during convalescence, in the first place to counteract the recoil influence of the flexion upon the round ligaments, and secondly to establish conditions favorable to the cure of the flexion. The only one of my cases that has given me any anxiety in regard to the anatomical success was one of retroflexion in which I did not insert a stem. For three or four months after operation the anatomical condition was one of retroflexion of the anteverted uterus. When last seen, the retroflexion was growing less, while the anteversion was securely maintained.

No one can seriously dispute the fact that shortening the round ligaments in their intra-abdominal course really shortens the distance between the fundus uteri and the abdominal walls, and thus holds the uterus in the position of normal anteversion and of suspension at the proper height in the pelvis. The objections to the operation are really based, not on theoretical, but on technical grounds—*i. e.*, the technique has heretofore not been satisfactory.

The principal difficulties in the performance of Alexander's operation, which have stood in the way of its popularity, are experienced, first, in finding the round ligament, and, secondly, in drawing it out when found. The following quotation from Mundé * will serve to emphasize the first difficulty :

> My great objection to the operation when I first attempted it was the doubt whether the ligaments could always be found. I heard this doubt expressed by experienced gynæcological surgeons who had tried and succeeded, and again tried and failed; and I myself had passed through this experience, being easily successful in my first, failing on one side in my second, and on both sides in my third case. I may say that it was with fear and trembling that I approached each Alexander's operation, never feeling sure that I would not disgrace myself by failing to find the ligaments, etc.

This difficulty of finding the ligament may also serve to explain the frequency with which the ligaments have been reported absent or wanting. In my eighteen operations I have found thirty-six ligaments.

My own difficulties have been experienced in drawing out the ligament when found, or in causing it to run satisfactorily.

Of ten ligaments in five operations performed after the usual method, four ran out satisfactorily to the extent of two inches or more; three ran out partially; in one instance I desisted from further traction, warned by the sense of impending rupture; and twice the ligament tore.

* The Value of Alexander's Operation for Shortening the Round Ligaments. *Am. Jour. of Obst.*, November, 1888, p. 1123

A brief consideration of the anatomy of the ligament will, I believe, serve to explain these results. Immediately after passing out of the abdomen, through the internal ring, as a compact, rounded cord, the fibers of the ligament separate, the greater number diverging to be inserted into the inner surface of the walls of the inguinal canal throughout its entire length. Comparatively few of the fibers pass out through the external ring to be inserted into the structures adjacent to the pillars of the latter.

In operating after the usual manner, it is this smaller bundle of the fibers of the ligament which is grasped and pulled upon in the attempt to draw the ligament out through the external ring. This minority of the fibers of the ligament is frequently not strong enough to stand the traction necessary to draw out the ligament from within the abdomen, especially as the firm attachment of the larger number of the fibers within the inguinal canal adds to the difficulty.

Another element to be taken into consideration in this connection is the direction of traction, which is manifestly most unfavorable. The abdominal part of the ligament runs outward to the internal ring; the part within the inguinal canal runs inward and forward. The two form a very acute angle with each other at the internal ring. In drawing upon its outer end, the ligament must be drawn over the sharp margin of the inner pillar of the internal ring at a very great mechanical disadvantage.

All these disadvantages are, to a great extent, overcome in my method of performing the operation. By laying open the inguinal canal, the round ligament is readily found and picked up. By picking it up as it emerges from the internal ring, the entire ligament is secured before any of its fibers are given off. This gives us in all instances a ligament sufficiently strong to stand the traction necessary to draw out efficiently its intra-abdominal portion. This more especially since we are at liberty, by reason of free access to the interual ring, to draw in the direction of the intra-abdominal portion of the ligament.

Another great advantage presented is the certainty of really shortening that portion of the ligament (the intra-abdominal), to shorten which is the prime object of the operation. As already stated above, upon traction being made upon the round ligament, the peritoneal folds of the broad ligament embracing it are drawn out through the internal ring in the shape of an inverted funnel. Under guidance of the eye the broad ligaments are gently stripped back from the round ligament, until the intra-abdominal portion of the latter is seen to have been liberated, for three or four inches of its length, from the embrace of the former. This denuded intra-abdominal portion of the ligament is converted into the extra-abdominal portion by being sutured into the inguinal canal.

The distinctive features of the method of operation advocated in this paper, briefly recapitulated, are as follows :

1. The inguinal canal is laid open along its entire length.

2. The round ligament is sought for and picked up at its point of emergence from the internal ring.

3. The ligament is drawn out approximately in the direction of its intra-abdominal portion.

4. The ligament is drawn out from its peritoneal investment by aid of the sense of sight. The shortening of its intra-abdominal portion is thus rendered a matter of absolute certainty.

5. The method of suture, which, while it closes the canal, at the same time secures the ligament within it.

6. The method of drainage by silk-worm gut.

Many and various are the modifications of Alexander's operation which have from time to time been proposed by different surgeons and gynæcologists. I am not aware, however, that the combination of procedures above described has ever been advocated. The nearest approach to it which I have found recorded is in a paper, read before the Gynæcological Society of Chicago, by Dr. Henry P. Newman, entitled Alexander's Operation, with Report of Cases,* to which I must refer for the details of Dr. Newman's technique.

An objection that may be urged against the plan of operation herewith presented, as compared with the original method, is the apparently greater probability of a resultant hernia. While I do not believe that the operation, carefully performed after either method, predisposes to hernia, I think a little reflection will show that the liability to this accident is really diminished in my modification.

In describing the technique of Alexander's operation, Mundé † says: "The operator need not be afraid to pass his finger or the scalpel handle along the ligament into the inguinal canal and break up these adhesions." Add to this dilatation of the canal the subsequent drawing down into it of the peritoneal pouch which follows the round ligament, and we certainly have established conditions not unfavorable to the formation of hernia. These conditions were clearly in the mind of Dr. W. L. Reid when he wrote:‡ "I also believe it wise to pass one or two deep sutures across the inguinal canal in order to occlude the pouch of peritonæum which is dragged down into it."

In my method the peritonæum is well stripped back from the round ligament and returned fully within the abdomen. The round ligament, denuded of its peritoneal coat, is in a condition most favorable to firm union with the internal wall of the canal, likewise denuded by the detachment of the fibers of insertion of the round ligament. The method of suture insures retention of the round ligament within the inguinal canal along its whole length. The walls of the canal are adjusted snugly around the contained ligament, and the lumen of the canal is now probably smaller than before operation.

As already stated, the object of this paper is to call attention to a method of shortening the round ligaments which I have thus far found easy of performance, and delightfully certain in its immediate anatomical results. That it constitutes a somewhat more serious procedure than the original operation I am free to admit. This is, however, more than counterbalanced by the greatly increased, I might almost say absolute, certainty of finding the ligaments, and the positiveness with which they can be really shortened when found. The hesitancy and lack of confidence with which I formerly approached the operation have given way to a feeling of assurance based upon the certainty of accomplishing that for which the operation is undertaken.

A CASE OF PRIMARY TUBERCULOSIS OF THE PHARYNX TERMINATING IN CURE.*

By J. W. GLEITSMANN, M. D.,

PROFESSOR OF LARYNGOLOGY AND RHINOLOGY IN THE NEW YORK POLYCLINIC, LARYNGOLOGIST AND OTOLOGIST TO THE GERMAN DISPENSARY.

The following history of a case of tubercular pharyngitis is presented to this learned assembly for two reasons. First, the successful treatment of cases of a similar nature is mainly due to the labors of two men, both of whom are members of this section, viz.: the introduction of lactic acid in the treatment of laryngeal phthisis by Krause, and its surgical treatment by Heryng. Secondly, the last examination, made more than two years after the commencement of the disease, showed that the patient remained perfectly well and that the cure had been complete:

The patient when presenting herself for treatment, May 14, 1888, was thirty-eight years of age, well built, weight one hundred and eighty pounds, no hereditary tendency. She called on account of pain in deglutition on the left side during the last two weeks. Inspection revealed an ulceration of the size of a pea, covered with grayish-white secretion, situated at the base of the tongue on the left side. The examination of the lungs at that time and at all subsequent periods showed them to be in perfectly healthy condition. Syphilis had to be excluded, as the patient had never had any symptoms of the disease; she was happily married and had given birth to six children, two of whom died from croup, and four were living and healthy.

The suspicious aspect of the ulceration tempted me to curette it thoroughly with the sharp spoon at her second visit. The specimens examined under the microscope by two independent observers contained numerous tubercle bacilli. The same condition was found one month later, when a piece of tissue removed from the edge of an ulceration was subjected to the microscopic test. The treatment during the entire course of the disease was confined to curettement of the ulcers and energetic application of lactic acid and at times use of the galvano-cautery. I kept purposely aloof from all alterative remedies in order not to obscure the case in any manner, the nutrition only being supported by tonics, good food, wine, etc.

The main features in the history of the case are the following, minor details being omitted: The primary ulceration improved in the beginning, but the latter part of June the destructive process extended along the base of the tongue toward the right side. Energetic treatment also arrested it in this locality, but in the beginning of August a deep ulcer was discovered in the posterior portion of the left tonsil. The ulceration was hidden by a flap of healthy tissue, and could only be seen by pushing the latter aside with a suitable forceps. A few days later the lingual surface of the epiglottis became intensely hyperæmic and uniformly thickened, resembling œdema. But on

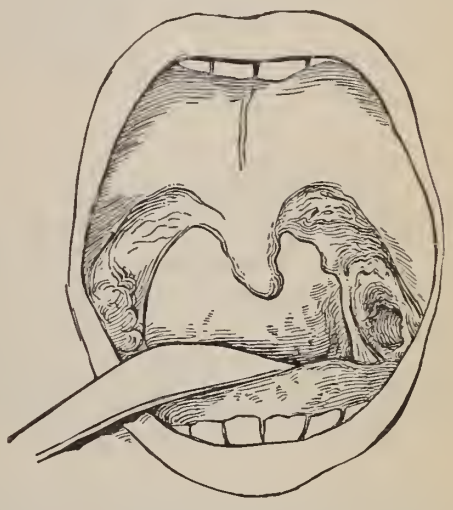
* Read before the Laryngological Section of the Tenth International Medical Congress, Berlin, August, 1890.

application of a probe no impression was produced, showing that a true infiltration existed. This condition remained stationary during the following month, but when returning from my summer vacation I found that the patient had lost ten pounds in weight and suffered from severe dysphagia. In trying to swallow liquids, the greater part passed through the nose. The lungs were again found to be intact. Scarifications of the infiltrated epiglottis were next attempted, but without giving relief. By the end of September, after a most thorough cleansing of the diseased parts, which I always found to be covered with copious and tenacious secretion, the whole infiltration of the lingual surface of the epiglottis proved to have melted away, and a large ulceration was visible instead, leaving only a small area of healthy tissue on the free border of the cartilage. On October 1st, ulceration set in on the left palatine pillar; on the 15th of the same month the remaining portion of the epiglottis was also transformed into an ulcer, and on the 20th the left arytæno-epiglottic ligament became involved. Although I had up to this time always entertained strong hopes of being able to combat the disease successfully, the condition of the patient was now certainly very discouraging, and I almost despaired of her ultimate recovery. Feeling that the last measures were justified, I scraped away all the diseased tissue most energetically without regard to the subsequent hæmorrhage and rubbed in undiluted lactic acid. The patient felt relief from pain the following day, and three days later cicatricial tissue appeared everywhere. Again three days later, October 29th, the patient felt perfectly well, and on the 31st the last eschar disappeared. The patient now weighed but one hundred and sixty-seven pounds.

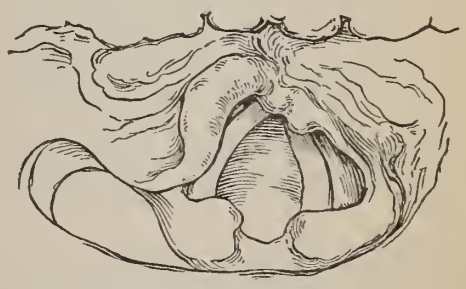
During the last week of November (1888) the patient was shown at a meeting of the laryngological section of the New York Academy of Medicine and examined by its members. They all confirmed the devastation made by the ulcerative process and the subsequent cicatrization. Ulceration could nowhere be detected at that time.

In regard to the treatment here pursued and its ultimate good result, it must be conceded that it was only possible owing to the great endurance and will-power shown by the patient throughout the whole time. Although the clearing of the ulceration was made with cocaine spray, all other proceedings only after application of the strongest solutions, necessarily the measures adopted and their after-effect were often very painful. Nevertheless, they were borne by the patient with the greatest patience and without the slightest objection. Another point which appeared to be of importance in the treatment deserves mention. It has already been observed by other writers that rubbing with the cotton-carrier over suspicious places aids in distinguishing between ulceration and cicatrization. It sometimes happens that a slight hæmorrhage occurs when we rub over apparent cicatricial tissue with a cotton-carrier, and that after a thorough cleansing an ulcer is discovered. If, however, after repeated rubbing, no change of suspicious places took place, I felt justified in considering them healed.

The further progress of the case was much simpler. In the beginning of December there appeared two discolored, whitish spots, corresponding to the posterior insertion of the ventricular bands, which remained visible during two weeks. Six weeks later the same observation was made at both processus vocales. Although first uncertain as to their nature, I had to consider them as the result of local anæmia, because the application of spray and cotton carrier proved them to be neither deposits of mucus nor ulcerations. A true ulcer formed in the latter part of December in the midst of the dense, hyperæmic left anterior palatine pillar. When treated with the sharp spoon, it proved to be of considerable depth. Its upper edge was cut away with a pair of scissors, and lactic acid was rubbed in. In the beginning of January, 1889, it became necessary to scoop out the freshly ulcerated left tonsil, and, two weeks later, a lobulated, suspicious-looking mass of the tonsil was removed with my irido-platinum wire. These two ulcers of the pillar and tonsil were the last ones to appear, and later on no more ulceration took place.



The two drawings of the pharynx and larynx, which I beg to present to the Section, date from this time (spring, 1889). The loss of substance at the left tonsil and the soft palate in one picture and at the epiglottis in the other are



plainly visible and require no further explanation. It is only proper to state here that already at that time the cicatricial tissue had to a great extent lost its irregular and contracted appearance, whereas previously the uvula was still more deviated to the left and the zigzag condition of the pillar considerably more developed.

In March, 1889, there appeared, as the last intercurrent affection, a tumefaction of the left sterno-clavicular articulation, which yielded to two months' treatment with simple remedies. In the beginning of this year the patient became pregnant, and was delivered of a healthy boy after my return from Europe in the fall.

I saw the patient and her well-developed, healthy child the last time on May 28, 1890. After the last two ulcerations (January, 1889) had healed, nothing abnormal could

be detected in the patient's pharynx or larynx, her weight had increased to two hundred and four pounds (twenty-four pounds more than at the beginning of the treatment), and she felt well in every respect.

I expressed it as my opinion, when I showed the patient before the New York Academy and also in the introductory remarks to this paper, that I considered the successful result obtained in this case entirely due to the application of lactic acid and the surgical treatment, in conjunction with the galvano-cautery. It is my firm belief that, with the necessary perseverance on the part of the physician and the corresponding energy on the part of the patient, such cases will not remain isolated in the future, and thus the statement made by a well-known author only a few years ago—"It is beyond doubt that up to this time no actually cured case of pharyngeal tuberculosis has been reported"—can not be considered an axiom any longer.

THE TREATMENT OF PERSISTENT ABDUCTION OF THE FOOT,

COMMONLY KNOWN AS CHRONIC SPRAIN OF THE ANKLE.*

By ROYAL WHITMAN, M.D., M.R.C.S.

The successful treatment of any chronic affection demands a personal, persistent attention to details on the part of the surgeon. This is particularly true of the treatment of what are known as minor injuries, and therefore neglected.

One of this class, to which I propose to call your attention, is commonly known as chronic sprain of the ankle, an affection which may entail years of discomfort and disability, with permanent impairment of the functions of the foot.

The usual history of such cases is as follows: Long-continued weakness and discomfort, following an injury to the ankle, treated by various physicians with liniments, blisters, and bandages until the discouraged patient is told that nothing more can be done, but that his symptoms "will wear away in time." A year or two later he presents himself, usually for the purpose of procuring a brace, or for some peculiar shoe which he thinks may be of service to him.

He complains principally of weakness, stiffness, and insecurity, of fatigue and pain in the foot and ankle on any overexertion. He walks with a somewhat awkward gait, the foot everted to avoid flexion at the ankle, with a very noticeable limp when fatigued; in fact, he walks as little as possible. On examination, one finds that the foot is abducted—that is, turned outward in its relation to the leg—that forced adduction and extension are resisted and are very painful to the patient. There may be some swelling, often of the dorsum of the foot, or in front and below the external malleolus. In other cases the ankle appears perfectly normal. The arch is not markedly diminished, but there is a prominence on the inner aspect of the foot, at the astragalo-scaphoid joint, caused by its abducted position. Thus, although in a well-marked case all the movements at the ankle and at the medio-tarsal joint are somewhat restricted, those of adduction and extension are almost lost, there being a spasmodic contraction of the peronei and extensor longus digitorum, with shortening of ligaments and fascia on the outer side, varying according to the time the foot has been held in its improper position. The amount of abduction varies. In many cases there is simply a slight limitation of adduction and almost no spasm of muscles. In others, usually in young subjects, there is a tonic contraction of the abductors, raising the outer border of the foot and throwing it into a position of marked deformity, presenting the appearances of what is sometimes called spasmodic valgus.

In making the diagnosis of this condition, it is important, as a preliminary measure, to test the movements of the foot—(1) in relation to its fellow; (2) to the normal range of motion. This varies considerably with the age or personal peculiarity of the patient, but, according to a number of measurements, the average is about as follows:

Forced flexion, 70° to 80°. Forced extension, 140° to 150°.

Adduction is much more difficult to determine, but it may be said that a person sitting, holding the leg perpendicular to the floor, the foot being somewhat extended, should be able to raise its inner border until the sole forms an angle with the floor of about 60° to 40°.

In this position the patient with persistent abduction of the foot is usually unable to raise the inner border at all.

I wish to call your attention particularly to the fact that a foot with persistently restricted motion in any direction, especially in that of adduction, is in no condition to recover under treatment by blisters, bandages, or rest, unaided by other means. Sprains of the character we are considering are usually caused by a fall from a height, or by the body turning outward over the foot, straining and rupturing the internal lateral ligaments, a more sudden violence producing in the same manner a Pott's fracture. Either as the direct result of the accident, or from the subsequent weakness of the internal ligaments, a subluxation of the astragalus takes place downward and inward, while the remainder of the foot is thrown outward, so that a disturbance of the muscular equilibrium results. The adductors, working at a disadvantage, are unable to perform their functions, while the abductors, the peronei, and extensor longus digitorum, in the effort to hold and steady the foot, are thrown into a state of spasmodic contraction, so that it is, as has been described, rigidly held in abduction, while the power of adduction is limited or lost.

Abduction of the foot is the position of weakness; adduction, that of strength and activity.

In other words, the usefulness of the foot depends upon the preponderance of power of the adductor muscles. When this is lost, weakness and pain ensue. If this proposition is accepted, the treatment becomes simple:

1. To overcome the contraction and spasm of the abductors.

2. To strengthen the adductors.

This can best be accomplished as follows:

The patient being etherized, the affected foot is forcibly

* Read before the American Orthopædic Association at its fourth annual meeting.

extended and adducted—that is, the heel and toes are both turned inward, so that the inner border of the foot is bent like a bow; it is then forced inward under the leg to a position of extreme equino-varus, the operation being attended with audible cracking of adhesions in all the disused articulations. In this position a well-fitting plaster bandage is applied, with the object of persistently overstretching the shortened ligaments and contracted muscles and holding the foot firmly in its new position.

The pain after the operation is much less than might be supposed from the violence that is often necessary to accomplish the result.

The bandage may remain on a variable length of time according to the subsequent pain and the difficulty that has been experienced in the reposition. From one to three weeks is the average time. When it is removed, the foot, though in good position, is usually somewhat swollen, sensitive to pressure, and all its movements are limited and often painful. Now a course of massage is necessary, gentle at first, followed by bandaging and complete rest. In two or three days, when the swelling has subsided, the patient begins voluntary exercises, assisted by the surgeon, the attempt being made to place the foot in the position of adduction—that is, to regain the motion that was lost. Thus, the patient contracts the adductors and flexors, while the surgeon aids, by gently pressing at the same time on the dorsum of the foot. At the conclusion of the exercise the surgeon, holding the foot firmly, turns it slowly inward toward the position of equino-varus, and retains it there until the involuntary resistance diminishes. This movement is usually accompanied by a very painful sensation of stretching in the muscles and ligaments of the outer border of the foot, which gradually diminishes as the foot returns to its normal condition. This portion of the treatment, described by the patients as "twisting," is by far the most important. Patients strongly object to it at first, but afterward submit to it willingly, as it relieves the sensation of painful stiffness, while the gain in range of motion after each application is very evident. When the pain and stiffness have diminished, usually in from one to three weeks, the patient is allowed to use the foot.

As the foot was formerly everted in walking, he now walks with the toes directly in front of the body, so that the flexors and adductors must be exercised with every step. He is to wear a Waukenphast shoe, as its inward twist aids in holding the foot in proper position. If necessary, its inner border may be built up, after the method of Thomas. I invariably use the foot brace, which has already been shown the society, to support the foot and prevent abduction until the patient by constant exercises and avoidance of improper positions has allowed the foot to return to its normal condition. These exercises are very simple:

1. The movements of adduction and extension which have been described.

2. Raising the body on the bare toes twenty to thirty times morning and night, as recommended by Ellis.

3. And most important, a correct walk, by which the body must be raised upon the foot at every step, as described in Vol. I of the *Orthopædic Transactions*.

The successful treatment of this class of cases may, I apprehend, be summed up as follows:

Discover what movements of the foot are restricted, with the apparent causes.

Then a persistent endeavor to overcome such restriction—

1. By forcible reposition to break up adhesions and to overstretch the contracted muscles and ligaments.

2. A long-continued massage intelligently applied by the surgeon.

It is not sufficient to order rubbing of the foot—this has been done by the patient for months—but a manipulation diligently carried out with the purpose of stretching the shortened ligaments and overcoming the contraction and spasm of muscles.

3. A re-education of the patient as to the proper positions and movements of the foot.

This course of treatment is often long, tedious, and painful, but it is, I believe, the only one which may restore the injured member to strength and usefulness, and if the patient and surgeon are not prepared to carry it out, it is better for both that the attempt should not be made.

Having spoken of the treatment of this affection, we may now consider how such a condition may be avoided.

The surgeon called upon to treat a recent injury to the ankle should remember that the subsequent disability is almost invariably the result of abduction, because the original injury is usually to the internal lateral ligament and those of the medio-tarsal joint.

Consequently, it seems reasonable, in a sprain of any severity, to place the foot for several days in a well-fitting plaster bandage in the position of adduction, to guard against a possible subluxation of the astragalus, and to relax the injured ligaments and muscles; then a course of massage until the swelling has subsided and all the movements of the ankle and foot have been regained and are painless, with the temporary use of a foot-brace if necessary.

In conclusion, the history of many of these patients would seem to show a very discreditable ignorance among physicians as to the appearance of a normal foot and of the injuries and diseases to which it is liable. A sufferer from non-deforming club-foot, persistent abduction of the foot, or flat-foot, usually goes from physician to physician only to receive a prescription for a new liniment or antirrheumatic medicine.

Even when a correct diagnosis is made, surgeons are too often content with temporary relief, rather than insisting on the persistent treatment which may result in cure.

Note.—The term "persistent abduction" is used simply to describe the actual condition of an affection which is not flat-foot, yet nearly allied to it. At the reading of this paper it was suggested that there were two distinct classes of cases presenting the appearances described, one of which was purely neurotic and might be cured without reference to the local condition of the foot. Such cases must be extremely rare. Disordered reflexes may increase the effect of a local trouble, and a poor general condition must be treated as well as the local affection; but, other things being equal, the writer believes that the best way to treat neuroses, if such exist, producing the symptoms above described, will be to break up the adhesions, to replace the foot in normal position, to strengthen and re-educate its muscles in the manner already described.

Edited by Frank P. Foster, M. D.

NEW YORK, SATURDAY, OCTOBER 11, 1890.

THE BACTERIOLOGY OF ACUTE CROUPOUS PNEUMONIA.

Dr. William H. Welch has reported to the Johns Hopkins Hospital Medical Society some of the results of his investigations regarding the bacteriology of acute croupous pneumonia. He has been able to discover the *Diplococcus pneumoniæ* in ten cases, all that were examined by him in this research, and to isolate the micro-organism in a pure culture. From a summary of Dr. Welch's remarks, given in the *Journal of the American Medical Association*, we learn, further, that he is inclined to accept the views of Fraenkel and others who teach that the diplococcus is the specific cause of the disease. In regard to Dr. Welch's culture experiments it may be said that he prefers the gelatin-agar medium, prepared according to the formula of Guarnieri: in that substance the growth of the pneumococcus was particularly luxuriant. He used other media, such as nutrient agar and glycerin-agar, making his cultures from the affected parts of the lungs, from the spleen, from the blood, and from various complicating lesions. In addition, mice and rabbits were inoculated with pieces of hepatized lung and of the spleen. In no instance was he able to produce pneumonia in the dog by means of any pneumococcus culture obtained by him; others, however, have attained to positive results by methods similar to those which failed in his hands. Dr. Welch observed in one instance that the presence of the organism would have been overlooked if he had not taken the precaution to make inoculations with bits of the tissues. He believes that the diplococcus should not be said to be absent simply on the ground of negative results from cultures: these results must be supplemented by the inoculation of susceptible animals. Moreover, the fact of failure to kill mice and rabbits by inoculations of the diplococcus from the human body is not conclusive evidence of the absence of the organism, since it may be found in man in a form that is incapable of destroying those animals. In some cases the pneumococcus did not kill rabbits, but did kill mice, making it evident that the latter are more highly susceptible and are to be preferred for the inoculation of tissues taken from the lungs in cases of croupous pneumonia. In three cases rabbits survived inoculation for more than five days, the longest duration being twelve days. When rabbits were inoculated with the exudation present in the bronchi or trachea, a speedily fatal result was sometimes obtained, even when the hepatized lung yielded a pneumococcus of diminished virulence.

The inference is very strong that the most virulent forms of the organism are to be found in the sputum, in the freshly hepatized lung, and at the margin of an advancing pneumonia, whereas the cocci present in advanced stages of hepatization and in the spleen are likely to be less virulent. In five of his cases there was a pleuritic exudate accompanying the croupous pneumonia, and this was examined by means of culture methods, revealing the pneumococcus in every instance. The organism has also been found in other cases of empyema following that disease. The pneumobacillus of Friedländer was not found in any case. These studies by Dr. Welch appear to confirm Fraenkel's statements as to the behavior of the *Diplococcus pneumoniæ* in artificial culture media, its susceptibility to slight changes in the composition and reaction of the medium, and its brief vitality. The frequent presence of the pneumococcus in health in the human saliva is an occurrence which, on the whole, must be of assistance in explaining the various factors that are concerned in the causation of croupous pneumonia. Dr. Welch deals with the history of the question briefly, giving to Dr. Sternberg the credit of the discovery, in 1880, of the salivary coccus, which he derived from his own buccal secretions and with which he inoculated rabbits at that time, producing fatal results. Dr. Welch does not adopt the term *Micrococcus Pasteuri*, given to the organism by Dr. Sternberg, and he does not appear to accept that which is more commonly used by European bacteriologists, for he speaks of it as "the so-called Fraenkel-Weichselbaum pneumococcus." These researches of Dr. Welch's have been made with great care and many precautions against possible error, and will convince not a few doubtful minds that the ætiology of croupous pneumonia is largely influenced by the *Diplococcus pneumoniæ*.

FURTHER ADVANCES IN CEREBRAL SURGERY.

Last winter we referred to the work of Dr. T. Claye Shaw in treating general paralysis of the insane by trephining. At the recent meeting of the International Medical Congress Mr. Victor Horsley spoke of the value of the operative treatment of certain neuroses and psychoses. In a case of athetosis, a symptom of which the pathology is obscure, though he believes it is always a sign of cortical lesion, the limbs had been progressively invaded, beginning with the thumb; he accordingly removed the thumb center. A paralysis of motion followed, lasting forty-eight hours; then the spasm returned in a measure in the parts supplied by the cortex bordering upon the excised portion. It was therefore necessary to remove the center for the whole limb; the operation was intended to relieve only the spasm and not the paralytic condition.

When operative interference in general paralysis and alienation is considered, Horsley believes that recovery from the disease is possible, though he has not had personal experience bearing on the point. His sanction of the potentialities of the operation was confirmed by the unique experience of Dr. Burckhardt, who has operated in six cases of psychoses. In two cases his aim was to intercept the paths of cortical association that, in his opinion, transmitted pathological impressions arising in sensorial and ideogenous portions of the brain; he has thus removed bands of the frontal and parietal cortex, anterior and posterior to the ascending convolutions. In one

case the result had been most satisfactory; in the second, that was still under treatment, the improvement had been only partial. The four other cases were accompanied with more or less acute hallucinatory delirium. The indication was to abolish, or reduce at least, the verbal hallucination as much as possible. But Dr. Burckhardt thought that the auditory verbal hallucinations could only be produced when the logogenic centers in the brain were in action. Verbal deafness and aphasia have acquainted us with two cortical centers for the formation of words, and Burckhardt believed that these centers were indispensable for the genesis of verbal hallucination. To cure the hallucinations it is therefore necessary to attack the centers directly and to excise portions of the first temporal and of the third frontal convolutions of the left cerebral hemisphere. In three cases the result was satisfactory, perhaps not final: but in case of a relapse it is intended to excise a portion of these convolutions again. In the fourth case, in which a very satisfactory result was expected, the patient died on the sixth day of cerebral vascular paralysis, due without doubt to the use of the scissors. But for this disaster the actual results were encouraging during the two years in which the work had been prosecuted.

These results are remarkable, and must be considered by those having the treatment of such cases within their hands. But cerebral surgery to-day affords the promise, both of success and of failure, that abdominal surgery has offered during the past decade; and a similar *furor secandi* will probably be manifested for some years, until larger experience teaches surgeons when to be bold and when to refrain.

CLOSTRIDIAL NEPHRITIS.

Dr. F. V. Hopkins, of San Francisco, has made a bacteriological study of a fatal case of renal disease, which has been reported in the *Pacific Medical Journal*. The patient suffered with a chronic affection of the kidneys and other organs, characterized by albuminuria, dropsy, nervousness, insomnia, flatulent dyspepsia, dyspnœa, and heart failure. Casts were present, which, in part, were made up of bacteria occurring in the form of rods with rounded ends. To this micro-organism Dr. Hopkins has given the name *Clostridium renale*, and he regards it as the cause of a peculiar form of chronic nephritis, which he would distinguish from the common forms of Bright's disease, under the term "clostridial nephritis." The bacterium occurs as circular cocci, as rods with rounded ends, and as filaments, in some cases tapering, and in others having the same thickness throughout their whole length. It is non-motile and infests the blood: from which it passes into the capillaries of the principal organs, which it obstructs. The organism is obtained in the urine, free and in casts, and is pathognomonic of clostridial nephritis. Dr. Hopkins's research included some cultivations of these bacteria, under proper precautions, and inoculations of rabbits were made, with the result of invariably causing in them a fatal dropsy and albuminuria, with the kidneys and other organs occupied by the germs.

Whether Dr. Hopkins's discovery of a new form of Bright's disease is confirmed by future observations or not, his work in this particular instance is instructive and exemplifies the importance of a bacteriological examination of the urine and casts. He has assumed that the renal affection in his patient was the primary and significant disease, whereas it may have been a secondary manifestation, due to a systemic bacterial infection, capable of invading the kidneys in common with various other structures. Dr. Hopkins makes bibliographical reference to the work of other observers who have reported cases of bacillar nephritis. Among these was Letzerich, who described in 1887 a series of twenty-five young persons who suffered from an acute renal dropsy which he called nephritis bacillosa interstitialis primaria. This disease is due to bacilli, which swarm in the urine, and may last from four to six weeks. Pure cultures of these organisms were made and rabbits were inoculated therefrom, causing ascites in about two weeks. The bacilli were found at the junction of the pyramidal and cortical portions of the kidneys.

MINOR PARAGRAPHS.

THE SUCCESSFUL REMOVAL OF A PANCREATIC CYST.

In the *Lancet* for September 27th, Mr. Frederick Treves reports the case of a man, aged forty, who was healthy until eight months preceding treatment, when a throbbing sensation was noticed in the umbilical region with subsequent pains, and general fatigue. A physician who was consulted discovered a swelling in the abdomen, so the man sought relief in a hospital. His expression was melancholic, his complexion was of a dirty-brown color, his pupils were contracted, and he showed great lassitude. The abdominal tumor extended from three inches above the umbilicus to the pubes, and laterally it occupied almost the entire front of the abdomen The growth felt smooth, and was firm, elastic, painless, and fixed; it could not be reached through the rectum. A space existed between it and the liver, and respiratory movements did not affect it. The pigmentation of the face and contraction of the pupils were ascribed to pressure on the solar plexus: the rapid growth suggested a sarcomatous tumor. The patient requested that an operation be attempted, and an infra-umbilical incision revealed a reddish-brown, smooth, retroperitoneal cyst. An incision into the cyst let out about a hundred ounces of thick, opaque, brownish-red fluid. The margins of the cyst wall were attached to the parietal wound by fourteen sutures, and a drainage-tube was inserted in the cavity. The discharge from the cyst was copious at first, but soon became thin and pale; it did not irritate the integument. The stitches were removed by the tenth day, but the patient remained in bed for almost six weeks. For two weeks after the operation he was apathetic and in the semi-somnolent condition of a person under the influence of morphine. When he was discharged, two months after the operation, a sinus still remained that did not close until a month later. Two years after the operation the patient was in excellent health.

LUNACY IN IRELAND.

On the 1st of January last there were held in district and private asylums, jails, poorhouses, and criminal asylums in Ireland 16,159 lunatics, being an increase amounting to 474 as compared with those on the 1st of January, 1889. This increase

is greater than at first sight it appears, inasmuch as the population of Ireland has of late years decreased considerably in consequence of emigration. As regards the condition of the insane scattered through the various workhouses, it can not be regarded as satisfactory, and the only plea for their detention at present is that they are destitute persons. As no legal power exists for their detention and safe-keeping, it is not to be wondered at that the provision for the proper care and maintenance of harmless lunatics and idiots in these institutions does not meet the requirements of this helpless class. The Inspectors of Asylums intend at an early date to report on the condition of the insane in the various licensed houses in Ireland, as they are of opinion that, with a few exceptions, they are not entirely satisfactory. Many contain but two or three patients, whose contributions toward their support will hardly admit of due provision being made for their proper care. The extension in Ireland of public hospitals supported by public grants, or charitable institutions for the reception of the insane whose friends are able to contribute only a small sum for their support, appears to be a want urgently felt.

A DEMONSTRATION OF THE AMŒBA COLI IN DYSENTERY.

In the *Johns Hopkins Hospital Bulletin* for September there is a note on a case of dysentery in a seaman, aged twenty-seven years, who had not been in the tropics since 1880, but had been attacked with bloody stools a week before his admission into the hospital. A microscopical examination of the stools by Dr. Lafleur showed numerous actively moving amœboid bodies of from five to seven times the size of a leucocyte; they were of a pale bluish-green color, and contained one or more small vacuoles surrounded by fine and often highly retracting granular particles, each body being invested by a homogeneous outer zone looking like finely ground glass. The outer layer would be slowly projected from some part of the surface in the form of a hemispherical knob, and the granular center of the body would then flow into this with a rapid motion. To detect these bodies, first described by Losch in 1875, the stools should be passed into a bed pan previously warmed with hot water and an examination of the discharge made at once. They are most abundant in the grayish-yellow pus collections. This was the first time they had been demonstrated to a medical society in this country.

THE NEW ST. FRANCIS HOSPITAL IN JERSEY CITY.

The new building adjoining the original hospital, in East Hamilton Place, was opened on Saturday, the 4th inst., with the ecclesiastical ceremonies customary with the Roman Catholic Church on such occasions, with the co-operation of the medical staff, the architect, and representatives of the clerical and medical professions in several neighboring cities. The hospital is under the care of the Sisters of St. Francis, and that fact of itself insures the excellence of its management. Its standing with the medical profession is correspondingly high; by many it will long be remembered as the scene of much of the good work done in surgery by the late Dr. Varick. The additional building now completed makes the hospital practically a new institution—one thoroughly equipped with the requisites of a modern hospital, including a medical and surgical staff of exceptional efficiency, enthusiasm, and singleness of purpose.

THE ACTION OF STROPHANINE.

According to the *Lancet*, Dr. Rothziegel finds that strophanine, the active principle of strophanthus, in doses of one three-hundredth to one two-hundredth of a grain daily, improves the circulation, strengthening the pulse, and attaining its full effect in two or three days. It relieved the dyspnœa, palpitation, and other symptoms occurring in organic heart disease; in time increased the flow of urine without irritating the kidneys; it did not produce gastric symptoms; it had no cumulative effects; and it only indirectly, but favorably, improved the nervous symptoms. It acted most rapidly when given subcutaneously, and it is said to be indicated in valvular disease with or without affection of the myocardium, while in Bright's disease it produces diuresis. Strange to report, the tincture of strophanthus acted more certainly and more quickly than the alkaloid.

CREOLIN IN THE TREATMENT OF CHANCROID.

The *Bulletin général de thérapeutique* for July 15th publishes an account of the experience of Dr. José Busque, of Pelotas, Brazil, in the use of creolin as an application to soft chancres. It was used in the proportion of from twelve to twenty parts of creolin to a thousand parts of water, and is stated to have caused the sores to heal rapidly even in cases in which the action of corrosive sublimate and that of iodoform had been tardy. However, the most rapid healing was secured by employing creolin and iodoform together.

METHYLENE BLUE AS AN ANODYNE.

The *Practitioner* cites from the *Pharmaceutical Journal and Transactions* an account of the results of the use of methylene blue as an anodyne in the Moabit Hospital in Berlin. Its employment in this way was suggested by its remarkable affinity for nerve-tissue, and especially for the axis-cylinder, in histological staining. When administered internally, even in the smallest doses, it could be detected in the urine in a quarter of an hour. It was found to act as an anodyne in various painful local diseases, such as neuritis and rheumatic affections of the muscles, joints, and tendon-sheaths.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 7, 1890:

DISEASES.	Week ending Sept. 30.		Week ending Oct. 7.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	61	11	39	3
Scarlet fever	27	3	28	1
Cerebro-spinal meningitis	3	3	2	2
Measles	25	2	43	4
Diphtheria	54	14	57	13
Small-pox	1	0	0	0
Whooping-cough	2	0	0	0

The Kings County Medical Association will meet on October 14th, at Kunzler's Hall, near the Post-Office, Brooklyn. The paper of the evening will be read by Dr. Nelson L. North, on The Medical and Surgical Treatment of Tuberculosis.

The District Medical Society of Northwest Missouri held a meeting in St. Joseph on Thursday, the 9th inst., under the presidency of Dr. James W. Heddens, of St. Joseph. The following were among the papers presented: When and how to use the Obstetric Forceps, by Dr. A. Goslin, of Oregon, Mo.; The Most Frequent Cause of Death after Abdominal Section, and its Prevention, by Dr. George Nash, of Maryville; A Function of the Colon, by Dr. M. Rhodes, of Graham; The Eye in General Diseases, by Dr. P. I. Leonard, of St. Joseph;

Pudendal Thrombus—History of a Case, by Dr. F. G. Thompson, of St. Joseph; Paraldehyde as a Hypnotic, by Dr. F. C. Hoyt, of St. Joseph; Excision of the Breast, by Dr. J. A. McKinnon, of Maysville.

The Medical Society of the State of New York.—The eighty-fifth annual meeting will be held in Albany on Tuesday, Wednesday, and Thursday, February 3, 4, and 5, 1891. The Business Committee has been appointed and is composed of the following-named gentlemen: Dr. Herman Bendell, 178 State Street, Albany, chairman; Dr. Seneca D. Powell, 12 West Fortieth Street, New York; and Dr. James D. Spencer, Watertown. The president, Dr. W. W. Potter, of Buffalo, says that all who intend to present papers should send the titles thereof to any member of the Business Committee not later than December 15, 1890, as the programme will be made up and issued early in January.

The Medical Society of the County of Ontario.—At the meeting to be held on Tuesday, the 14th inst., in the Court House in Canandaigua, at 10.30 A. M., Dr. Charles H. Richmond, of Livonia Station, will report a case of intestinal anastomosis for fæcal fistula, and reports of other cases of interest are expected.

The New Tariff and Medical Books.—Some of our readers may not be aware that under the new tariff law foreign medical books printed in any other language than English are admitted without the payment of duty.

Changes of Address.—Dr. Charles H. Chetwood, to No. 120 East Thirty-fourth Street; Dr. H. Newton Heineman, to No. 60 West Fifty-sixth Street; Dr. George A. Peters, to No. 45 West Thirty-fifth Street; Dr. Royal Whitman, to No. 126 West Fifty-ninth Street.

The Death of Dr. Montrose A. Pallen took place on Wednesday, the 1st inst. He had long been in poor health, and his death was not unexpected. The deceased was for a time a member of the faculty of the Medical Department of the University of the City of New York, and previously of that of one of the St. Louis colleges. During his active professional career he was a prominent gynæcologist.

The Death of Dr. Cosmo Brailly, of New York, occurred on Sunday, the 5th inst., at Hazlet, N. J., where he had been spending the summer. He was a native of France, but had practiced medicine in New York for nearly fifty years.

Society Meetings for the Coming Week:

MONDAY, *October 13th:* New York Academy of Medicine (Section in Surgery); New York Ophthalmological Society (private); New York Medico-historical Society (private); New York Academy of Sciences (Section in Chemistry and Technology); Lenox Medical and Surgical Society (private); Boston Society for Medical Improvement; Gynæcological Society of Boston; Burlington, Vt, Medical and Surgical Club; Norwalk, Conn., Medical Society (private); Baltimore Medical Association.

TUESDAY, *October 14th:* Tri-State Medical Association (first day—Chattanooga); New York Medical Union (private); Kings County, N. Y., Medical Association (Brooklyn); Medical Societies of the Counties of Albany (annual), Chenango (tri-annual), Greene (semi-annual—Cairo), Jefferson (quarterly—Watertown), Oneida (quarterly—Utica), Ontario (quarterly—Canandaigua), Rensselaer, Schoharie (semi-annual), Tioga (quarterly—Owego), and Wayne (semi-annual), N. Y.; Newark, N. J., and Trenton (private), N. J., Medical Associations; Bergen, N. J., and Cumberland (semi-annual), N. J., County Medical Societies; Litchfield, Conn., County Medical Society (annual); Baltimore Gynæcological and Obstetrical Society.

WEDNESDAY, *October 15th:* Tri-State Medical Association (second day); Harlem Medical Association of the City of New York; Northwestern Medical and Surgical Society of New York (private); Medico-legal Society; Medical Society of the County of Allegany (quarterly), N. Y.; New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society.

THURSDAY, *October 16th:* Tri-State Medical Association (third day); New York Academy of Medicine; Metropolitan Medical Society (private); New Bedford, Mass., Society for Medical Improvement (private).

FRIDAY, *October 17th:* New York Academy of Medicine (Section in Orthopædic Surgery); Chicago Gynæcological Society (annual); Baltimore Clinical Society.

SATURDAY, *October 18th:* Clinical Society of the New York Post-graduate Medical School and Hospital.

Letters to the Editor.

MASSAGE IN SWEDEN.

STOCKHOLM, *September 15, 1890.*

To the Editor of the New York Medical Journal:

SIR: This attractive and picturesque city in the North, built on several islands on Lake Mälar and an arm of the Baltic Sea at the point where the two meet, and laying claim to the titles of "The Venice" and "The Paris of the North," is rapidly making good another claim, "The Mecca for Gynæcologists"; for since some four years ago, when Major Thure Brandt went to Jena at the invitation of Professor Schultze, of that place, and subjected his method of treating cases of pelvic affections to the close scrutiny and criticism of that distinguished gynæcologist, physicians in great numbers, from Germany, Austria, Russia, and a few from other countries, have flocked here to see and acquire the method. When we reached Norway about three months ago, we wrote to Major Thure Brandt expressing our desire of working under him for a time. The reply was courteous, short, and prompt in making its appearance. It stated a condition of having to agree to remain two months should he think it necessary. Having accepted the condition, we accordingly presented ourselves on the morning of the 1st of September, and were shown into a large and artistically furnished parlor to await the master. In a few minutes a man well advanced in years (seventy-one), but with a firm and elastic step, military bearing, a fine physique, and a finely shaped head well poised on broad shoulders, entered and extended to us a cordial welcome with a warm shake of the hand.

Every morning (excepting Sunday) at eleven o'clock the patients present themselves for treatment. They congregate in a large waiting-room, devoid of carpet, and around the three sides of which are ranged a number of low couches and cane-bottom chairs, with high, straight backs. Here they are put through a number of gymnastic movements by a bright, intelligent little woman — Miss Johnsson, Brandt's assistant. On watching these manipulations for the first time, as each patient in turn was subjected to a certain manœuvre, then let alone for five or ten minutes, to be taken up again for a different exercise, the impression produced was rather comical. One recalled Lord Dundreary's system of "taking exercise in compartments." But a longer observation revealed the facts that each patient was provided with a formula of the movements to be carried out, that each movement had a distinct object in view relative to the disease with which the patient was suffering, and that, in accordance with an old law in medical gymnastics, a certain interval must intervene between the execution of the different exercises.

Major Thure Brandt always applies the special treatment of the pelvic contents himself in a separate room—*i. e.*, he never intrusts it to his assistant. One is not here long before he is fully convinced of the utter futility of trying to learn the method from books and articles—a fact insisted upon by every one who has written on the subject after having seen Brandt work.

Another point which one soon learns, and which also has been freely expressed by the same writers, is that this non-medical man possesses a diagnostic skill which would put to shame many an eminent gynæcologist. His knowledge of the anatomy of the contents of the abdomen and pelvis is extensive, and in the main correct. This is not the time or place to express an opinion on his method, which also requires a fuller acquaintance and a longer observation than we have as yet gained. But so much we can venture to say, that the impression so far is extremely favorable, and that much more can be accomplished with it, in a certain class of cases, than we had thought it possible before coming here. Whether this layman will prove to be another veritable Preissnitz is, perhaps, at this stage, too early to predict. But too much praise can not be bestowed upon him for his conscientiousness, his earnestness, his generosity, his sacrifices, and his self-disinterested desire to propagate his system and to relieve suffering womankind.

This city, as is well known, is the home of medical gymnastics and massage. A visit, therefore (in fact, we have already made many), to the Central Gymnastic Institute is not only interesting but profitable. At our first visit we were conducted through the building by the genial, courteous, and highly cultured Professor L. M. Törngren, the chief of the institute. Every part and contrivance was shown and fully explained in excellent English by the professor. On entering one of the rooms, we took by surprise a number of bright-looking girls, each poring studiously over a work on anatomy and some bone of the human frame. The number of very fine human skeletons and bones in this room surprised us in turn, as did also the information that the students had to follow the dissection of six whole bodies each session for two sessions. How many of our medical schools call for as much from their students? The students are also given a good grounding in physiology and in the diagnosis and pathology of those diseases amenable to treatment by medical gymnastics and massage. Before receiving a diploma the student must have attended two full sessions of eight months each, and have passed a creditable examination in the foregoing subjects. But, for fear some of your readers, who are sending patients to Swedish masseurs and masseuses, on reading this will fall into a false security, I hasten to add that Professor Törngren assures me that there are only three of their graduates in the whole of the United States, and that not one of these is living in New York city. Of course, New York may, nevertheless, have some very competent masseurs and masseuses, but it is well to bear in mind the foregoing circumstance when subjecting one's patient to treatment by massage. This treatment, which has grown so much in fashion with us lately, as it is witnessed here, though capable of doing much good in certain cases, is certainly capable of inflicting much harm when done injudiciously or by untrained persons.

H. N. Vineberg, M. D.

EXTRACT OF PINUS PALUSTRIS AS A VULNERARY.

Charleston, S. C.

To the Editor of the New York Medical Journal:

Sir: I wish to call the attention of the profession to a treatment which, so far as I know, is original, and with which I have had marked success in the treatment of fistula in ano.

After the proper surgical procedures have been carried out, a strong extract of lightwood (*Pinus palustris*) in alcohol is applied. This very adhesive preparation glues together the edges of the wound and thus insures quick and healthy union. The advantages alleged for this treatment are: 1. That the divided tissues are kept firmly held together, and thus their union is quickly attained. 2. The extract of lightwood acts as a healing agent, stimulating to just such a degree as is necessary to bring about quick and healthy union. The utility of this mode of treatment, I am quite sure, will be very evident to all who give it a fair trial, and it will, I am equally sure, supersede the time-honored use of styptics in these cases. The extract may be used either with a syringe or else applied directly by a suitable instrument when the tract, sinus, or broken tissues are in view. Of course, the application should be made daily, or so long as the parts do not appear firmly united. The extract of lightwood is simply made by placing in a small quantity of alcohol a number of shavings of fat lightwood, gauging the quantity so as to get an extract of a syrupy consistence.

Whenever, then, the close apposition of surfaces after surgical procedures is necessary to bring about healthy union, the application of this extract will meet the indication and will, indeed, take the place of sutures in those parts of the body where they are inapplicable. Allard Memminger, M. D.

*** In a supplementary letter, Professor Memminger informs us that the extract is made from only those parts of the tree that have been converted into "lightwood," and from which much rosin is exuding, such as the knots of the trunk of a tree that has been felled for some time and is elsewhere undergoing decay.

Proceedings of Societies.

RICHMOND ACADEMY OF MEDICINE AND SURGERY.

Meeting of August 26, 1890.

The President, Dr. W. W. Parker, in the Chair.

(*Reported by Dr. J. W. Henson, Richmond.*)

Symptoms of Cocaine Poisoning from Half a Drachm (per rectum) of a Three-per-cent. Solution.—Dr. Ramon D. Garcin reported that six weeks or two months since he had been called to see Mr. F, who had been operated upon by an irregular, who was out of the city when the speaker was called. When he had reached the man he was suffering intensely, and morphine hypodermatically not relieving him, half a drachm of a three-per-cent. solution of cocaine was administered *per rectum*. No relief of pain had ensued, but in a short time breathing had become quickened, extremities cold, pulse rapid and weak. The man had described his flesh as tingling like the sensation felt upon first grasping the poles of a galvanic battery. By the use of stimulants he had soon rallied.

Dr. J. P. Roy asked if the muscles of deglutition were affected.

Dr. Garcin replied that they were not.

A Case for Diagnosis.—On July 8, 1890, Dr. Garcin said that he had been called to see Mr. M., aged nineteen years, who had complained of intense nausea and pains resembling cramps in the region of the epigastrium. The history of the case before this was negative. He had been to work up to the day before taking his bed, although a week previously there had been a slight diarrhœa for a few days; but when the doctor was called the man had said that his bowels were in a normal condition. His tongue was very slightly furred, temperature (by mouth) 98·5° F., and the abdomen, especially about the umbilical region, was very tympanitic. A distinct gurgling (exactly resembling that of typhoid fever) was present in both iliac fossæ. The bowels had been moved once that day.

The speaker had given a simple anodyne for the cramps, which had soon afforded relief, and dilute hydrochloric acid, fifteen drops every four hours.

July 9th and 10th.—Patient about the same; bowels acting once daily. A mixture of equal parts of turpentine and sweet oil was ordered applied over the iliac region. He had from the first ordered liquid diet. The temperature was normal; taken once that day.

12th.—The characteristic diarrhœa of typhoid "pea-soup" discharges; temperature normal, morning and evening. Tympanites being more decided, fifteen drops of turpentine in emulsion every six hours was ordered.

13th, 14th, and 15th.—Tympanites decidedly diminished. Diarrhœa worse toward evening; three, four, and sometimes five discharges from 3 P. M. to 6 or 7 P. M. The speaker ordered fifteen drops of dilute hydrochloric acid and ten grains each of lactopeptine and bismuth subnitrate every four hours.

16th and 17th.—Patient seen for the speaker by Dr. R. T. Ellis.

18th, 19th, 20th, and 21st.—Bowels not so bad; tympanites had disappeared; slight gurgling in right iliac fossa; no fever.

22d.—Pulse and temperature normal; bowels moved once; tongue healthy.

The interesting features of this case, said the speaker, were (1) entire absence of fever, morning and evening; (2) absence of the typhoid tongue; and (3) absence of coma, the man being conscious throughout the attack. The after-treatment had been a tonic of vin Mariani. The patient was out by August 1st.

The PRESIDENT asked if there was any history of phthisis?

Dr. GARCIN replied No.

Dr. J. M. WINFREE—Any pain, mucus, or blood?

Dr. GARCIN—Some pain; no mucus or blood.

Dr. T. J. MOORE—How long was the man sick?

Dr. GARCIN—About three weeks.

Dr. MOORE—Did Dr. Garcin see him when first taken?

Dr. GARCIN—Yes, when he first took to bed; but he had been complaining before, although at work up to the day before the first visit.

Dr. MOORE—What was his work?

Dr. GARCIN—Apprenticed lithographer.

Dr. MOORE—Did he work in lead?

Dr. GARCIN—Yes; a little in mixing paints.

Dr. MOORE stated that the symptoms were so obscure it was impossible to make anything like an accurate diagnosis.

When a person was subjected to the gradual and prolonged absorption of lead, there occurred sometimes a condition where there was no manifestation of colica pictonum proper, but a certain degree of constipation followed by an irritative diarrhœa. Possibly this patient was so affected. The diurnal normal temperature excluded typhoid fever. There was sometimes a condition of bowel where a local irritation of a diarrhœic character congested and caused ulceration of Peyer's patches; this might give the characteristic pultaceous stools with the fœtor of typhoid actions, accompanied by tympanites. Mere tympanites occurred in so many conditions that it was not calculated to lead up to a diagnosis. Tenderness in the ileo-cæcal region was more directly prognostic.

Abscess of the Parotids complicating Typhoid Fever.—The PRESIDENT had seen, in a boy aged sixteen years, abscess of each parotid gland as a complication of typhoid fever. Each abscess had discharged from the ear before being lanced, the discharge through the ear ceasing after the lancing. The point was that the boy had recovered, though some one had stated that all cases of typhoid fever with abscess about the parotid gland proved fatal.

Dr. MOORE said that several years since Dr. R. M. C. Page, of New York, had written an article on secondary parotiditis in which he had stated that when suppuration of the parotid gland arose as a complication of typhoid fever, nearly all cases so affected proved fatal.

Dr. ROY had had a similar case to Dr. Parker's last autumn occurring in about the third week of typhoid. As in Dr. Parker's case, each abscess had discharged from the ear. There had also been an accompanying cancrum oris—a spot of gangrene of the size of a silver dollar appearing on the outside of one cheek before death, which had followed soon.

Aneurysm of the Arch of the Aorta.—Dr. LEWIS C. BOSHER had been called in consultation with Dr. Jones to see a colored woman who was suffering from the effects of a pulsating tumor occupying the upper part of the left side of the thorax. He had found a patient about thirty-five years of age who was exceedingly emaciated and suffering greatly from pain, dyspnœa, and extreme debility. She had little or no appetite. On examination, the tumor, which had measured about three inches by three inches and a half at every point, had given a distinct pulsation corresponding to the cardiac systole. The stethoscope gave only an indistinct bruit. The sternum had appeared to project forward, and there was a complete dislocation of the left clavicle at the left sterno-clavicular articulation. He diagnosticated the tumor as an aneurysm of the arch of the aorta, which had projected forward, pressing against the sternum, ribs, and clavicle, and causing absorption of the former and dislocation of the latter. On Saturday night last this patient had died, and yesterday, with the assistance of Dr. C. A. Blanton, Dr. Daniel J. Coleman, Dr. Jones, and others, a post-mortem was made which had confirmed the diagnosis. A sacculated aneurysm, springing from the arch of the aorta and projecting forward and upward, had dislocated the left clavicle at its sternal end and had caused absorption of some of the upper ribs as well as the sternum at the junction of the manubrium and gladiolus. There was a slight rupture in the sac from which there had been probably a slow leakage of blood, thus accounting for the gradual, rather than the sudden, death, such as results from sudden rupture and copious hæmorrhage. The left side of the thorax was filled with blood.

A Limit to Life in Organic Heart Disease should be set with Caution.—The PRESIDENT had reported, two or three years ago, the case of a man, aged about seventy-five years, with enlarged and valvular disease of the heart. Pulse had been 24 per minute for months at a time. While under his observation—a period of about two months—he had apparently died four or five times a day. At the end of two months he had left town—now over two years since. He had just died a few days ago.

A doctor should be careful how he limited life in a person with organic heart trouble. As illustrative, the speaker told of a man named Shook, the action of whose heart (from hypertrophy) had been so violent as to shake the bed. After being in bed several months, he had got up and walked about for one or two years.

Mastoiditis in the Negro.—Dr. W. F. MERCER asked if anybody had ever seen mastoiditis in a full-blooded negro. Dr. T. E. Murrell, of Little Rock, Arkansas, had stated that mastoiditis was never seen in a full-blooded negro. In a dispensary practice of six years (the majority of the patients negroes too) the speaker had never seen a case in a full-blooded negro until within the last two months—one case occurring in a man. His only evidence that he was full-blooded was his appearance and statement.

The PRESIDENT had had a case in a mulatto. This had been operated upon by Dr. J. A. White, but death had occurred in three or four weeks afterward.

Continued Fevers.—The PRESIDENT had seen some time ago a case of fever with Dr. O. A. Crenshaw, who, a great believer in typhoid fever, had insisted that this was typhoid for

some time; but it was not. The woman had been badly treated by her husband. The speaker thought it an irritative fever. It had terminated favorably after three or four weeks' duration. It was not usual, though, to see a continued fever unless it be typhoid. He had seen numbers of cases of slow-pulse typhoid before the war. The amount of prostration, however, proved them to be typhoid to his mind. He was now attending a young lady who had had typhoid fever in Charlottesville. Supposed to be decidedly convalescent, she had been brought here two weeks ago to escape diphtheria. Moving had done a great deal of harm. Her temperature was now 103° F. She could not walk five steps now without help. He had been called on Saturday night to see a young man in the same house with the young lady. His temperature was 103°, and he had presented the symptoms of cold—flushes and steams alternating with cold chills. The speaker thought it a general inflammatory fever or a sort of general rheumatism. He had given him calomel and soda then, and on Sunday quinine, five grains every four hours. On Monday he was in a profuse cold sweat, pulse feeble, no fever from symptoms, bowels and tongue pretty good, appetite bad except for liquids. He thought he would soon be better. Tuesday (to-day) his temperature was 103°. Perspiration gone. Skin hot.

The speaker had forgotten to say that he had had two hæmorrhages from the nose on Monday night. He thought the case peculiar, and was uncertain whether it was typhoid or not.

Dr. M. D. Hoge, Jr., asked if there was any cough?

The President replied, None.

Dr. David McCaw—Had the patient been given any antipyrine?

The President—None. Had Dr. Moore seen any cases of continued fever not typhoid?

Dr. Moore replied, Yes.

The President—What was the pathology of them?

Dr. Moore stated that every fever was continued in which there was no intermission—for example, remittent malarial fever. What was the president's idea of continued fever?

The President thought typhoid and typhus continued fevers, but not malarial fever.

Dr. Moore stated that he had seen a form of fever this season that had corresponded neither in type nor characteristics to either remittent or typhoid fever.

He thought the lines were too sharply drawn by the writers concerning the continued fevers common to various sections of the United States. We saw occasionally in this part of Virginia a form of fever congestive in type (attributable to heat and the peculiar atmospheric conditions), with high and irregular diurnal thermometric ranges, great rapidity of pulse, congestion and tenderness of spleen and liver, congestion of kidney, a certain amount of tympanites, and of uncertain duration, lasting often from ten days to two weeks. It did not yield to quinine, while alterative doses of mercury modified the disease and shortened the duration of the fever. It was accompanied by a bilious diarrhœa, yielding best to bismuth and opium. Typhoid existed in all parts of the United States. It was most prevalent and violent in type in high altitudes. It hugged the mountains and a belt of Piedmont country contiguous thereto. It was also found in the low country and in Tertiary formations. It was modified in many of its symptoms by the effect of prolonged heat and the structural alterations of the glandular organs, particularly the spleen and liver, by malarious influences. The speaker was not referring now to the disease called typho-malarial fever. The cause of typhoid fever had never been ascertained. Scientific men had offered many suggestions without definite results. Sewer-gas was often mentioned as the vehicle by which the specific poison was conveyed. In many places, especially mountainous sections, both sewers and sewer-gas were unknown. Running and well water were both frequently thought to contain the specific poison. He did not believe a specific cause or germ had been definitely ascertained. He related how an old Tennessee doctor, unlettered but experienced, at some convention had stated that he knew nothing of germs and the other new-fangled notions in regard to the cause of typhoid fever, but that whenever he could induce any of his families to locate their stables and hog-pens at a sufficient distance from their houses, and remove their chip-piles at the proper seasons, he noticed that such families were not troubled with typhoid fever. Typhoid differed markedly in regard to the severity of attacks, embracing from the walking cases upon the one hand to the malignant upon the other. In regard to the perspiration mentioned by the president, he had seen frequently profuse sweats in the first week of conception of typhoid fever, but usually there was a dry skin.

The President remarked that in some parts of East Tennessee the people forty years ago had never heard of sewers or sewer-gas, or of typhoid fever. But he spoke of an old gentleman, owning about seventy-five negroes, and who had lived seven miles from his nearest neighbor, and the fact that a while later typhoid broke out among his slaves, though, as stated before, it had not been heard of previously.

MEDICO-CHIRURGICAL SOCIETY OF MONTREAL.

Meeting of May 30, 1890.

The President, Dr. G. Armstrong, in the Chair.

Sudden Death from Rupture of a Gummatous Tumor of the Heart-wall.—Dr. John A. Hutchinson exhibited the heart of a young man who had died suddenly. He had not known him at all during life, but had good reason to believe that he had been under treatment for syphilis. The heart had been removed by order of the coroner, and a caseous tumor, probably a gumma, had been found in the wall of the right ventricle. This had broken down on its inner side, and its contents, which were almost liquid, had escaped into the ventricle.

Obstruction of the Bowel by a Gall-stone followed by Spontaneous Relief.—Dr. Bell exhibited a gall-stone of a round outline as large as a walnut which had been passed *per anum* under the following circumstances: The patient, a spinster aged sixty-seven, had enjoyed good health, with the exception of an obscure illness somewhat resembling typhoid fever three years ago. The present illness had begun with abdominal pain and discomfort, and it had soon become evident that an acute obstruction was present. Abdominal section had been proposed but obstinately objected to by the patient. Subsequently repeated enemata had been employed. On the sixth day the bowels had moved spontaneously and this huge gall-stone had been found in the fæces.

Enormous Vesical Calculus.—Dr. Hingston exhibited an enormous stone, weighing a few grains over five ounces, which he had that day removed from the bladder of an elderly man by the lateral method. He compared it with a stone nearly as large which he had removed by the same method sixteen years ago.

The Distribution of the Lesions in Chronic Phthisis.—Dr. I. G. McCarthy read the paper of the evening with this title. After rapidly reviewing the advances made in the study of tuberculosis, he explained the theory of localization of the tubercular lesions of the lung enunciated in 1888 by Dr. I. Kingston Fowler, of the Brompton Hospital for Consumption, and related his own experiences of many chest cases examined in that hospital, while he was attending Dr. Fowler's clinic,

where he had opportunities of verifying the doctrines of his teacher. He had found, too, that "the disease in its onward progress through the lungs, in the majority of cases, followed a distinct route from which it was only turned aside by the introduction of some disturbing element." This doctrine was based upon numerous post-mortem examinations and an extensive clinical experience. It had been long established that the apex of the upper lobe—that was, the apex of the lung—was the usual site of deposit, and that it was generally the part to be first affected. Fowler had defined two points as the sites of the primary lesion. The one most frequently found was situated from an inch to an inch and a half from the summit of the lung and nearer the posterior than the anterior surface. On the chest this corresponded to a point above the clavicle, or immediately below the center of that bone; posteriorly it was in relation with the supraspinous fossa. Hence, the examination of the supraspinous region was of the utmost importance. The disease next tended to spread downward at about three fourths of an inch from the surface of the lung anteriorly, and was mapped out on the chest-wall by a line corresponding to an inch and a half from the inner ends of the first, second, and third interspaces. The disease here was made up of new foci occurring in nodules, with normal lung-tissue intervening. As the disease progressed, a time would come when, by the softening and extension of these nodules, there would be physical signs of extensive disease anteriorly. But this did not take away from the fact that the disease, in the first instance, occurred nearer the posterior surface and tended to spread backward.

The other and less frequent site of the primary lesion was in relation with the first and second interspaces, below the outer third of the clavicle. It spread downward, and an oval portion of lung was involved. The middle lobe was rarely primarily affected. The next point at which the disease showed itself was situated in the apex of the lower lobe of the side primarily affected. The disease occurred here early, long before there was extensive disease at the apex of the lung. It was possible that there was special vulnerability at these two points, the apices of the upper and lower lobes. This secondary lesion was situated about an inch and a half below the upper and posterior extremity of the lower lobe, and about the same distance from its posterior border, which corresponded on the chest-wall to a point situated midway between the fifth dorsal spine and the border of the scapula; from this focus the disease spread along the interlobar septum. A rough surface mark of this line of invasion was obtained by making the patient place his hand upon the opposite shoulder, when the vertebral border of the scapula in its new position would indicate approximately the line of the disease. Tubercles next appeared at the apex of the lung heretofore free, and next at the apex of its lower lobe.

As regarded the exceptional cases where the base was first attacked, the reader inclined to the theory that such cases were not really basic phthisis, but were the outcome of some non-tubercular affection which had weakened this part of the lung and left therein a suitable nidus for the bacillus.

Wound of the Scrotum with Protrusion of the Testis.—Dr. J. A. Hutchinson related the history of an accident which had happened to one of his patients who had been riding, when the horse had reared and fell on him. The scrotum had become crushed between the thigh and the pommel of the saddle. The pain and sickness produced had been intense. The speaker had found the man in a condition of collapse. After an anæsthetic had been administered it was found that the testis had been pushed through the scrotal tissues and protruded through a button-hole opening, which had to be enlarged so as to permit of the replacement of the viscus. The subsequent course of the case was satisfactory.

CANADIAN MEDICAL ASSOCIATION.

Twenty-third Annual Meeting, held at Toronto, September 9, 10, and 11, 1890.

(*Concluded from page 358.*)

Spinal Syphilis.—Dr. Finley, of Montreal, read a paper on this subject. Allusion was made to the various diseases of the cord following syphilis, such as locomotor ataxia, Landry's paralysis, and myelitis. Gummatous formations were next dealt with. It was pointed out that in these cases only could brilliant results be looked for from the use of antisyphilitic remedies. An early diagnosis was essential for successful treatment, before destruction of the nerve tissue had occurred. Permanent damage not infrequently was a result of disease in this region, and in certain cases remedies had but little effect. Three cases were reported illustrating different phases of the disease.

The first was that of a female, aged thirty-four, who had previously been under treatment for headaches, and who had presented syphilitic scars, was seen in January, 1889, with an ataxic gait, weakness of the legs, girdle sensations, and irregularly distributed areas of hyperæsthesia and anæsthesia on the trunk and legs. She had also had formication in the legs and occasional incontinence of urine. Under the influence of mercurial inunctions and iodide of potassium these symptoms had completely disappeared, with the exception of the girdle sensation. In this case it was believed that a gumma pressed on the cord, and that the ataxia was due to involvement of the posterior columns. The iris reflexes were normal and there was no change in the optic discs.

A second case occurred in a man aged twenty-three, who had acquired syphilis three years previously. Pains and weakness in all the limbs had come on within a fortnight. There were weakness of all the limbs, a girdle sensation, and anæsthesia of the greater part of the trunk and limbs to touch and pain. With the same treatment the sensory symptoms had disappeared, but the paresis still persisted. A subacute diffuse myelitis had probably existed which was not greatly influenced by treatment. The rapid disappearance of the sensory symptoms might be accounted for by disappearance of an accompanying gummatous outbreak.

The third case, in a man aged thirty-four, was also a myelitis, and was chiefly interesting as coming on within eight months of acquiring primary syphilis, and was followed shortly afterward with a right-sided hemiplegia due to thrombosis.

Pernicious Anæmia.—The paper of Dr. A. McPhedran, of Toronto, contained the histories of five cases of pernicious anæmia which he had had under observation. In the first case there were delirium, high temperature, chills, and gastro-intestinal disturbance. The red blood-corpuscles were typical—731,000 to the cmm. Arsenious acid to the extent of a quarter of a grain a day was taken for two months. Recovery was complete in seven or eight months. In his second case the symptoms were moderate—606,000 corpuscles to the cmm. The administration of arsenic had to be suspended every few days on account of epigastric pain, and in four months was stopped altogether, when the corpuscles had reached 2,600,000. Recovery was complete in ten months. In the third case the disease was followed by parturition and was not very severe. Insanitary surroundings were a probable cause. In six months recovery was complete. The fourth case was complicated by la grippe, and in its main features simulated malignant disease of the stomach. Arsenic, even in minute doses, could not be tolerated. No im-

provement as yet. In the fifth case there appeared to have been a previous attack, the same symptoms having been present two years previously. This patient was now taking arsenic and making considerable progress toward recovery.

In all five cases there was gastro-intestinal disturbance, with high-colored acid urine, not increased in volume, and of low specific gravity. These characters were specially marked during exacerbations of the disease, when in one case (the fourth) renal casts were found. These had contained much pigment, as well as yellowish pigment masses which had disappeared as the exacerbation passed off. No microscopic examination was made in the first three cases, and no pigment was found in the urine in the fifth case, but the patient had had no paroxysm of the disease since he came under observation.

The works of Hunter, Mott, and others showed that the disease was characterized by excessive hæmolysis occurring in the portal system, due probably to some poison, possibly a ptomaine or some of the many organic compounds that might be absorbed from the intestinal tract. The treatment advised consisted essentially in intestinal disinfection—thymol, β-naphthol, and naphthalin being the most effective agents. The administration of arsenic in minute doses at short intervals, and a diet of the hæmatogenous foods, were also recommended.

Hemiatrophy of the Tongue of Peripheral Origin.—In the course of a paper upon this subject Dr. H. S. Birkett, of Montreal, related the history of a male patient, aged twenty-three, who, on examination, had presented the following conditions: The right half of the tongue was markedly atrophied, but tactile sense and the sense of taste were not impaired. The right side of the soft palate was paralyzed, and sensation was diminished in the buccal mucous membrane and the naso-pharynx. Adduction and abduction of the right vocal cord were very limited. There was persistent myosis of the right pupil. There was a thickened and infiltrated area, situated on the right side of the neck, just in front of the anterior border of the sterno-mastoid muscle, and at a level of a line drawn backward from the angle of the lower jaw on the same side, pressure on which produced flushing and sweating of the right side of the face, with dryness of the throat, which all passed off when the pressure was removed. There was never any difficulty in deglutition, but speech was at first interfered with, especially for words containing the letter "r"; pulse, 98. Physical signs negative. The nerves involved were the hypoglossal, the vagus, accessory, the branches of the pharyngeal plexus, and the superior cervical ganglion of the sympathetic. These nerves appeared to have been involved in a large and painful swelling at the angle of the lower jaw on the right side, which had come on during convalescence from an attack of mumps nine years ago. The speaker's deductions were as follows: 1. The hypoglossal was the motor and trophic nerve of the tongue. 2. The glossopharyngeal nerve was concerned in the function of taste. 3. The branches of the pharyngeal plexus supplied the mucous membrane of the buccal and nasal pharynx with sensation. 4. That the motor nerve of the levator palati and azygos uvulæ muscles was probably the accessorius. 5. That the superior cervical ganglion of the sympathetic contained (*a*) dilator fibers to the iris of the same side, (*b*) vaso-motor, (*c*) sweat, and (*d*) special secreting nerve fibers.

Peri-urethral Cellulitis.—Sir James Grant, of Ottawa, narrated the history of the case of a man, aged forty, who had suffered from an extravasation of urine in 1879. He had previously developed a stricture following a gonorrhœa. A large portion of the integument of the scrotum had sloughed in consequence of the extravasation, and a fistulous opening had remained in the perinæum, leading down to the membranous urethra, through which urine had flowed freely. The parts had granulated readily. An attempt was made to pass a catheter into the bladder by the urethra, and this had rather unexpectedly succeeded. The catheter was secured in the bladder and left *in situ* for three days, during which time the urine had flowed freely through the instrument, none escaping through the perineal fistula. At the end of the third day the catheter was removed and the urine had subsequently flowed through the natural channel: healing had rapidly occurred in the perinæum. The case was cited to demonstrate the marvelous reparative power of granulation tissue even under the most adverse circumstances.

Dr. Shepherd did not think that three days was sufficient time for healing by granulation to take place in an old-standing fistula, although it might occur in a recent case. He considered Dr. Grant very fortunate in the result he had obtained.

Cholecystotomy.—Dr. Shepherd, of Montreal, read a paper on this subject. After giving a short account of the history of the operation, he stated that, although it was frequently performed in Europe, it had been but seldom performed in America. The difficulties of the operation varied greatly in different cases. When the gall-bladder was distended and could be brought up to the abdominal walls the operation was comparatively easy; but when the gall-bladder was shrunken and small or altered by the products of inflammation, the operation of cholecystotomy might become one of the most difficult in surgery. He also spoke of the great difficulty of diagnosis of gall-stones in some cases, and how, until an exploratory operation was performed, no positive diagnosis could be given. He gave the history of a case in which he had performed the operation and in which the diagnosis was very obscure: The patient, a lady aged fifty-one, had been in failing health for a year, suffering from pain in the epigastrium and great discomfort after eating. Six weeks before consulting Dr. Shepherd she had been suddenly seized with a severe pain in the abdomen, with incessant vomiting and great tenderness; there had also been elevation of temperature. Her medical attendant had now for the first time discovered a tumor to the right of the umbilicus, which was tender on pressure and freely movable. During the next few weeks the patient had had several similar attacks, and since the first attack had never been free from pain and discomfort about the abdomen, especially after eating or moving about much. When the speaker first saw her there was a well-defined tumor of about the size of a fœtal head to the right of and beneath the umbilicus; it was smooth on the surface, but deeper down was hard and irregular; it was freely movable, dull on percussion, and tender to the touch. After a careful examination of the case and consultation with colleagues, it was thought probable the case was one of malignant disease of the bowel, and an exploratory incision was advised and consented to. On opening the peritoneal cavity in the median line over the tumor, an elongated portion of liver was first met with, and beneath this a large, hard, nodular mass covered by omentum and bowel. The gall-bladder could not be found, so the liver was carefully separated from this mass, and, although there was free hæmorrhage, the connection was not very firm. A gush of fluid from the tumor had disclosed a small cavity in which were situated two large gall-stones joined together; these were extracted and the finger pushed in through a constriction into a space in which was another large stone, which was with difficulty removed. The edges of the cavity which contained the gall-stones consisted of inflammatory tissue, and were so friable that they could not be brought to the abdominal parietes. However, the space between the abdominal walls and altered gall-bladder was filled in by omentum and a portion of the elongated liver lobe. A rubber drain was introduced into the bottom of the cavity, the liver replaced, and the abdominal

wonnd closed. The patient rallied well from the operation and had no vomiting; the temperatnre was normal throughout. For some days there was a profnse discharge of bile through the tube, but this had ceased altogether on the fifteenth day after operation. The patient was out driving daily in the second week, and went home in less than a month without any sinus, and feeling better than she had for years.

The speaker drew attention to the fact that even after the abdomen was opened it was a difficult thing to say whether the tumor consisted of new growth or inflammatory tissne; the gall-bladder was so altered as to be unrecognizable. In this case the elongated portion of liver represented what had been called the lacing lobe, the lacing furrow being over the region of the cystic duct and neck of the gall-bladder; pressure here caused stagnation of bile and the formation of gall-stones. The writer concluded by saying that the resnlt in his case pointed strongly to the advantage of exploratory incision in doubtful and apparently hopeless cases.

Dr. Chown, of Winnipeg, in discussing Dr. Shepherd's paper, mentioned a case of long-standing janndice where an exploratory incision was made. The pancreas was irregularly enlarged and was occluding the common bile duct by direct pressure. The gall-bladder was pushed to the right of the tnmor. The central incision was closed and a second one made over the gall-bladder on the right. The bladder was stitched to the edges of the incision and opened, when bile escaped. Six weeks had now passed since the operation, and the patient continned to pass all the bile through the fistnlous opening. The jaundice had disappeared, but there was no change in the tumor.

Appendicitis.—Dr. George Armstrong, of Montreal, read a paper npon this subject, dealing especially with the important question as to the time at which an operation shonld be performed. He urged upon all practitioners to bring forward and publish their cases, both successful and unsnccessful, in order that we might be placed in a position to decide upon an established procedure, and he assnmed that on the following points all were agreed: 1. That the cæcum and appendix were entirely surrounded by serous membrane and were intraperitoneal. 2. Primary infiltration of cellular tissue in the right iliac fossa was nnknown. 3. There was no evidence of the existence of an infiltration of the walls of the cæcum other than that caused by a catarrhal infiltration or nlceration of its mucous membrane, the most common forms of nlcer being stercoral, typhoid, tubercular, and perhaps syphilitic. 4. The symptoms of a catarrhal infiltration of the mucous membrane of the cæcnm were those of a colitis rather than typhlitis, and ulceration of the cæcnm did not give rise to symptoms of typhlitis unless the peritoneal covering became involved.

The reader dwelt npon the importance of early recognition of the disease, and upon the fact that every one of the symptoms might be very slight. A little pain on pressnre might be the only symptom present to indicate the presence of a pint of stinking pus. A case was cited, that of a girl of twenty-one, in whom the symptoms had been very mild and there had been apparent improvement nntil the fifth day of the illness, when symptoms of general peritonitis had been observed. Abdominal section had been performed. The appendix had been found to be perforated. The patient had died a few hours afterward.

In a second group of cases the inflamed appendix was completely snrrounded by the products of inflammation, so that further changes in the tissne were prevented from contaminating the general peritonæum, at least for a time. In such cases the use of an exploring needle had been recommended, bnt the speaker had had little experience of its nse. A distended gnt conld not be pierced with impunity. With regard to medical treatment, the amount of opium used shonld be the smallest qnantity that would insure a fair degree of comfort to the patient, lest the symptoms be masked and the trne condition of affairs not be rendered evident to the friends of the patient. Purgatives shonld be avoided. A mild enema was all that could safely be nsed. Under snch treatment recovery might ensue. It was probable that merely a catarrhal appendicitis had been present. But apparent recovery was no certain indication that the appendix was whole, and in proof of this a case was cited where, after complete recovery, a second peritonitis had occnrred. Here the abdomen had been opened and a qnantity of pus removed, the patient making a complete recovery. In a third case the appendix was removed successfully dnring the period of qniescence. The paper was brought to a close by an earnest appeal for early operation.

Book Notices.

Familiar Forms of Nervous Disease. By M. Allen Starr M. D., Ph. D., Professor of Diseases of the Mind and Nervous System, College of Physicians and Surgeons, New York. With Illustrative Diagrams and Charts. New York: William Wood & Co., 1890. Pp. xii–339.

This is a most practical book and one of great value to the student and general practitioner. Chapters of interest and moment are by Dr. Frederick Peterson, Dr. Walter Vought, Dr. Winslow W. Skinner, Dr. Edwin Swift, and Dr. M. L. Goodkind. Thus it will be perceived that to the author's trained comprehension of his subject are added the earnest thonghts and conclusions of other well-endowed medical observers. There is not a word too much in the entire work. Dr. Starr's command of English is especially felicitous, and his style forcible and clear—qualities of great importance in the exposition of nervous disease. The chapters on localization, cerebral function, and the motor area are instructive to a degree. Whoever reads, learns, marks, and inwardly digests this book will recognize familiar forms of nervous disease and know how to treat them within given limits.

Les anesthésiques: physiologie et applications chirurgicales. Par A. Dastre, professeur de physiologie à la Sorbonne. Paris: G. Masson, 1890. Pp. xi–306. [Prix, 5 fr.]

In this work an attempt is made to snrvey the field of anæsthetics critically and analytically, and from a brief reference to ancient anæsthetics—inclnding, of conrse, a reference to that French pioneer in scientific discoveries, Denis Papin—the author reviews the history of the discovery of laughing-gas, ether, and chloroform. These common anæsthetics are then taken up and considered at length, physiologically and therapeutically. Chapters are devoted to chloral, bromide of ethyl, chloride of methylene, the chloride, acetate, and benzoate of ethyl, amylene, and methyl chloroform, cocaine, mixed anæsthesia, and local anæsthesia.

We note that the chapters on chloroform were written before the report of the Hyderabad commission was published, and the anthor's conclnsions regarding the toxic effect of chloroform are directly opposite to the resnlts obtained by that body. In summing up between ether and chloroform, he concludes that the former should be given when the condition of the patient or other causes presage the possibility of secondary syncope, or when a lesion of the right heart consequent npon chronic lung disease exists. But in prolonged operations, in cases of lesion of the left heart, and, lastly, in children, chloro-

form is preferable. We can commend the volume to all desirous of information regarding the various anæsthetics.

Miscellany.

Whitehead's Operation for Hæmorrhoids.—At a recent meeting of the Philadelphia County Medical Society, Dr. Charles B. Penrose read the following paper:

My object in presenting this paper is to urge the more general use of Whitehead's operation of excision in the treatment of certain cases of hæmorrhoids.

In 1887, Mr. Whitehead, of Manchester, reported * three hundred consecutive cases of hæmorrhoids which had been successfully treated by the method of excision and suture. His operation is performed in the following manuer: 1. The patient is placed on a table in the lithotomy position, with the hips well elevated. 2. The anal sphincters are then thoroughly paralyzed by digital stretching. 3. The mucous membrane of the rectum is divided at its junction with the skin around the entire circumference of the bowel. 4. The mucous membrane, with the attached hæmorrhoids, is dissected from the submucous tissue, and the cuff or cylinder thus formed is dragged below the skin margin. 5. The mucous membrane above the hæmorrhoids is then divided transversely, thus removing the pile-bearing area, and the operation is completed by suturing the upper margin of the severed membrane to the free margin of the skin.

The advantages alleged by Whitehead for this method of treatment are based on pathological and on surgical reasons. He considers that internal hæmorrhoids, which are generally regarded as localized distinct tumors, amenable to individual treatment, are, as a matter of fact, component parts of a diseased condition of the entire plexus of veins surrounding the lower rectum, each venous radicle being similarly, if not equally, affected by an initial cause, constitutional or mechanical. The operation of excision is the only one which removes this whole diseased area. It is, therefore, demanded for this pathological reason. It is in addition surgically more perfect than any other method of treatment, because it provides for the readjustment of healthy tissues with the object of securing primary union and rapid convalescence. It does not leave the sluggish ulcer of the cautery, nor is it attended with the pain and slow convalescence of the ligature.

My experience with this operation is limited to ten selected cases. Only those cases were selected in which there existed a complete circle of hæmorrhoidal tumors surrounding the lower margin of the rectum, since for such cases Whitehead's treatment of excision seems to be most particularly adapted.

The details of the operatiou are simple and easy to execute. In dividing the mucous membrane from the skin it is best to begin at the posterior margin of the anus in order to prevent the blood from obscuring the field of operation. No skin should be sacrificed, even though there appear to be redundant tags arouud the margin of the anus. The skin always retracts somewhat and the tags shrivel aud disappear before firm union has taken place. Failure to observe this rule may result in subsequent serious trouble. Kelsey † reports the case of a woman who had been subjected to a so-called Whitehead operation and who presented herself to him with a complete circle of excoriated mucous membrane, extending for one inch outside the anus. It is probable that in this case the operator had sacrificed too much skin.

On the other hand, the upper section of the mucous membrane should be made in the same horizontal plane throughout, in order to prevent subsequent ectropion ani.

The dissection of the mucous membrane from the underlying tissue is exceedingly easy except in some cases of old—or long-standing—piles. The attachment of the submucous tissue is very loose, and separation can be effected with the finger or with the handle of the scalpel. It is not always possible to dissect the piles completely from the underlying structures, as they may involve not only the mucous but the submucous tissues, and in such cases it is necessary to cut partly through the piles until the healthy mucous membrane above is reached. Repeated attacks of inflammation of course render closer the adhesion of the pile area to the underlying structures. In one of my own cases, where the piles had existed for forty years, and had frequently been inflamed, the adhesions to the two sphincters were so close that a few muscular fibers were cut away during the removal.

The amount of blood lost during the operation is surprisingly small. Whitehead states that he has often operated on severe cases and not

* *British Medical Journal*, February 6, 1887.

† *New York Medical Journal*, October 5, 1889.

found it necessary to twist a single vessel. In five of my cases no hæmostasis was necessary. Bleeding is avoided by adhering closely to the mucous membrane in the dissection, as the larger arterioles lie beneath the submucous tissue. The arterial bleeding occurs in those cases of old piles which have been subjected to previous operation or to attacks of inflammation, and in which dilatation of the rectal and anal arteries has taken place secondary to dilatation of the hæmorrhoidal veins. The bleeding from the upper divided edge of the mucous membrane can be reduced to a minimum by following Whitehead's method of inserting the sutures as each portion is divided, or by adopting Marcy's plan of introducing a circle of shoemaker stitches of catgut around the mucous membrane above the piles before cutting the mass away.

Whitehead's advice is in all cases to remove the complete cylinder of mucous membrane, whether or not the whole of this area appears to be diseased. He gives this advice for the reason which I have already stated, that he considers the individual piles as but part of a general pathological condition, involving all the lower hæmorrhoidal veins of the rectum.

Whether we accept this pathological view or not, it is best to follow this plan, and to make a complete circular division of the mucous membrane, as by this method the best surgical results are obtained, and ectropion ani prevented. I have seen a case in which only one half of the circumference of the mucous membrane of the rectum was removed, and a few hours after the operation an œdematous swelling formed in the other half, which has now resulted in a hæmorrhoidal tumor almost as annoying as the one for which the operation was performed.

In attaching the mucous membrane to the skin, Whitehead uses the interrupted silk suture. He never removes the sutures, but allows them to ulcerate through—a process which is very easily accomplished. In my own cases I have used the continuous catgut suture.

The treatment of these cases after operation is very simple. It is rarely necessary to use opium or the catheter. An opium and belladonna suppository, introduced immediately after the operation, is in most cases all that is required. The bowels can be moved in from twenty-four hours to four days, and with very little pain. Absence of pain after Whitehead's operation is due to the thorough paralysis of the sphincters and to the fact that no source of irritation is left beyond that of a clean linear incision, united without tension and without strangulation of tissue.

A glance at the histories of my own cases shows that they were all cases of aggravated hæmorrhoids in which the piles covered the whole circumference of the lower part of the rectum. In all the cases the disease had existed for many years, and two had been subjected to previous operation by the ligature.

In only one case was there anything like free bleeding during the operation.

In all the cases a suppository of half a grain of extract of opium and half a grain of extract of belladonna was introduced immediately after the operation, and this was all the opium required except in three cases, in which one sixth of a grain of morphine was subsequently administered.

The catheter was used in only three cases, and in these for a period not longer than twenty-four hours. The length of time that the patient is confined to bed depends to a great degree upon his social standing and disposition. In my cases it varied from two to ten days. Every patient should be able to sit up in four or five days, and to resume work in ten days or two weeks.

The bowels were opened without pain in from twenty-four hours to four days after the operation.

No complications of any kind followed these operations. Union takes place quickly, and generally one dressing, taken off when the bowels are moved, is all that is necessary. In no case was there incontinence from paralysis of the sphincters, or any tendency to stricture, from contraction of the scar.

Since the publication of Whitehead's paper his method of operating has been tested by many surgeons. The operation can not be criticised on surgical grounds, as it is certainly the most perfect plan of treatment, surgically speaking, which has been proposed.

The immediate removal of the tumors, the coaptation of healthy tissues, and primary union, are substituted for slow strangulation by the ligature, or removal by the cautery and healing by granulation.

The applicability, or the necessity, of this operation in all cases of hæmorrhoids, is, however, open to criticism. If we accept Whitehead's views in regard to the pathology of piles, and believe that the whole venous plexus surrounding the anus and the lower end of the rectum is in a pathological condition in every case of hæmorrhoids, even though there may be present only one or two isolated tumors, then, of course, the complete removal of this area is indicated.

But that this view is not true is proved by the thousands of cases which have been permanently cured by the ligature and the clamp. The method, however, is indicated in all cases of aggravated hæmorrhoids where the vascular tumors cover the whole or the greater part of the circumference of the bowel. In such cases the operation presents no great difficulties. Statistics show that it is at least as safe as operation by the ligature or the clamp, and it is certainly followed by a more rapid convalescence, and much less pain and discomfort.

Pulmonary Consumption and the Board of Health.—*An Open Letter to the Board.*—GENTLEMEN: The Board of Health has seen fit to issue rules to be observed for the prevention of the spread of consumption. If this proclamation had been intended for the medical profession it might be looked upon as harmless, but the nine commandments are distinctly addressed to the public at large.

The chief points in this remarkable document may be summed up as follows:

1. "Consumptives are respectfully requested not to spit on the floor or on cloths, but into a solution of corrosive sublimate."

This is laudable as far as it goes.

2. "Do not sleep in a room occupied by a person who has consumption. The living-room of a consumptive patient should have as little furniture as practicable. Hangings should be especially avoided. The use of carpets and rugs ought always to be avoided."

This is cheerful, to say the least.

3. "Do not fail to wash thoroughly the eating-utensils of a person who has consumption as soon after eating as possible, using boiling water for the purpose."

The effect of this is to make it painfully plain to the patient that he is an outcast and an object of well-merited disgust.

4. "Do not mingle the unwashed clothing of a consumptive person with similar clothing of other persons. The soiled clothing of a consumptive person should be removed at once, put in boiling water for forty-five minutes, or otherwise disinfected."

In other words, the family of the patient are told to look upon him as a leper. This, too, is refreshing.

5. "Do not fail to catch the bowel discharges of a consumptive person with diarrhœa in a vessel containing corrosive sublimate one grain to water one pint."

This paragraph is commendable on the grounds of common decency.

8. "Household pets (animals or birds) are quite susceptible to tuberculosis; therefore,

"Do not expose them to persons afflicted with consumption; also, do not keep, but destroy at once, all household pets suspected of having consumption, otherwise they may give it to human beings."

This is laughable, because it is not true. It is the comedy part of this otherwise very serious melodrama.

Before submitting to your honorable Board a few questions, let me say that I am far from believing that in issuing this remarkable document you were actuated by other than the best of motives. And now will you kindly tell me—

1. Do you not know that there are many forms of so-called consumption, ranging from pleuritic adhesions, peribronchitis, and other connective-tissue processes to suppurative conditions and the invasion of the tubercle bacillus? Do you not know that all of these conditions are accompanied by more or less cough and expectoration—an expectoration free from the much-dreaded bacillus in over seventy per cent. of all cases of so-called consumption?

2. And if you did know it, how came you to address a circular to

the general public advising them to shun as nuisances all persons who cough and expectorate?

3. Upon what evidence do you base your belief that it is dangerous to sleep in the same room with any one "suspected" of being a consumptive?

4. Who told you that the clothing of a consumptive—let it be a bacillus consumptive this time—was a source of infection to persons in good health?

5. How in the world did you learn that even the tubercle bacillus itself ever infected any one except by direct inoculation? You will tell me it is a fair inference. I know that. An inference is on a par with a possibility, a possibility is not a probability, and even a probability is several removes from a fact.

Laboratory experiments have produced tubercular consumption by artificial inoculation in animals, not in man. If you want to find out that clinical experience does not justify you in assuming that consumption—not even tubercular consumption—is contagious, be good enough to consult the *Transactions of the Medical Society of the State of Pennsylvania* (June, 1890), and look for the Address in Hygiene, by Thomas J. Mays, M. D., of Philadelphia. On page 8 of the reprint of this excellent address you will find this: "Now, in converging the evidence of the two sides of this question, there appears to be an irreconcilable contradiction. The experimental testimony points decidedly toward contagion, while the clinical testimony just as decidedly opposes such an opinion. It must be remembered, however, that the first kind of evidence pertains only to experiments on the lower animals, and, in so far as it applies to the human body, rests entirely on a theoretical basis." And again: "All that they (the experiments) show is that the disease may be transplanted by a certain method, after it has been called into existence by other causes."*

Again I quote from page 10 of the same pamphlet: "Take away the inoculation experiments on animals and you destroy the corner-stone on which those who believe in the communication of consumption from man to man repose their belief."

And on page 11: "Moreover, the contagiousness of consumption is an old idea, and all the measures of prevention which are receiving serious consideration from those who believe in it at the present time were tested *with disastrous results* by the inhabitants of Naples more than a hundred years ago. They reasoned as follows: If consumption is contagious, then the separation of the afflicted from the well is the only logical remedy; and for sixty-six years—from 1782 to 1848—they enacted and enforced the most rigorous laws that have ever been introduced for the suppression of any disease."

What you have published as a well-intended warning to the public will do no good, but a great deal of mischief. So far as the public is concerned, it will create a far-reaching and permanent panic in the minds of people who were well and happy before they read your untimely announcement. A family with consumption in its midst will be shunned. So far as the sufferers from chronic coughs are concerned—and your circular includes all of them under the heading of "suspected"—they will be regarded as a public pest, and will be forced to undergo a degree of social ostracism hitherto experienced only by the victims of leprosy.

In conclusion, I can not withhold an opinion shared by many of my colleagues, and it is this: It strikes me that occasional petty tortures are invented by the Board of Health for lack of something else to do.

All of which is respectfully submitted.

J. Hilgard Tyndale, M. D.

Thunder and Sour Milk.—"The effect of thunder-storms in turning milk sour is a matter of constant observation in every household. It is not certainly known to what element in the air this souring action on milk is to be directly attributed, and most people are content to ascribe it to 'electricity in the air.' An Italian *savant*, Professor G. Tolomei, has lately made some experiments with the view of elucidating this question. He found that the passage of an electric current directly through the milk not only did not hasten, but actually delayed acidulation, milk so treated not becoming sour until from the sixth to the ninth day, whereas milk not so electrified became markedly acid on the third day. When, however, the surface of a quantity of milk was brought close under the two balls of a Holtz machine the milk soon became sour, and this effect he attributes to the ozone generated, for when the discharge was silent the milk soured with greater rapidity than when the discharge was explosive, in the former case more ozone being formed than in the latter. The souring of milk is generally attributed to the growth of a ferment (bacterium), which converts the milk sugar into lactic acid. It is possible, then, that the presence of ozone in the air overlying the milk hastens the growth and multiplication of the bacterium. The first observation—namely, the retardation of souring by the passage of a current through the milk—may be a point of practical importance to milk traders. Any methods of preserving milk from its first retrogressive changes, which does not involve the addition of extraneous substances (antiseptics) to the milk, and which is at the same time cheap, effective, and not likely to prove injurious to the consumer, is sure to be welcomed at a time when milk is sent long distances to market, and is often stored for a considerable time before it reaches the consumer."—*British Medical Journal.*

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Lectures and Addresses.

DIATHESIS AND CACHEXIA.

A CLINICAL LECTURE,
DELIVERED AT THE PHILADELPHIA HOSPITAL.

BY ERNEST LAPLACE, M. D.,
PROFESSOR OF PATHOLOGY AND CLINICAL SURGERY IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA; VISITING SURGEON TO PHILADELPHIA HOSPITAL, ETC.

LECTURE III.

REPORTED BY WILLIAM BLAIR STEWART, M. D.

THERE are two words—diathesis and cachexia—which are used frequently by all of us, which for a long time represented something that was very obscure to our minds; it is often several years before an accurate knowledge of these two terms is attained by the average medical student. Although not defined in the same way by all medical authorities, it is well to have a definite idea of every subject about which we talk. It may be that in time what we talk about now will be modified somewhat.

Therefore, from the very first, the meaning of diathesis is an inherited condition or predisposition to get a disease, while a cachexia is an acquired condition when the body has ceased to be in its normal state by having passed through some pathological condition. We speak of the malarial cachexia in a person who, once perfectly well, had malaria, but who recovered with the malarial appearance remaining. A child born of tuberculous parents, coming into the world with its physiological condition below par, is born with the tubercular diathesis. From time immemorial it was evident that parentage had something to do with health and disease. Such is the case among animals that are affected according to the condition of their parents or species. Since that is the case in lower animals, how much more forcibly must this be in man! In fact, civilization is to man what domestication is to animals. Having drawn clear lines of distinction between diathesis and cachexia, and having a positive notion on this subject, let me clear up, as far as is in my power to do, those points that are not clear in your mind.

The word diathesis you hear indiscriminately used in connection with scrofulosis and tuberculosis. A child is born of tuberculous parents. The child need not have any evidence of the actual existence of tuberculosis in his system. This fair-haired, bright-skinned, blue-eyed child, the wonder of the neighborhood, who is not strong, grows in a puny condition, has a delicate appetite, grows with other children—this child has a tuberculous diathesis, and is only waiting to develop tuberculosis when a favorable opportunity presents itself. Two children fall and each receives an injury. The one is laid up for one or two days and is all right again. The other, our fair-haired child, from the injury to its knee develops tuberculosis in that joint. Both of these children from birth had been breathing the germs of tuberculosis, and were apparently none the worse for it, but both fell and received a contusion in the knee joint. One recovered. This fall formed that unknown something that was wanting to develop tuberculosis in the fair-haired child, otherwise it would have developed the same in the other. What do we understand when we say a child has scrofula? A child suffering with scrofula has tuberculosis of the lymphatic glands. From the time the glands begin to manifest themselves by enlargement they are tuberculous and the bacilli are growing there. White swelling is tuberculosis of the knee joint. There are no reliable cases on record to warrant the fact that a child has been born with fully developed tuberculosis in its system. A child is born with the tubercular diathesis, and, sooner or later, develops tuberculosis, manifesting itself either in the glands as scrofulosis; in the meninges of the brain as tuberculous meningitis, or abscesses of different kinds; or, later in life, tuberculosis of the lungs, the most fatal form. All these are acquired because the child has been born with the tuberculous diathesis.

There are many among us who, if they lived up to the laws of hygiene, would not become tuberculous; but there are few of us who, if imprisoned in a damp place, with improper food and poor light, would resist the germs of tuberculosis that we now breathe with impunity. It is not possible for us to acquire tuberculosis until we acquire a condition suitable to it, and that condition is cachexia. Leaving tuberculosis, we take up syphilis; that is an affection in which a diathesis appears, but, unlike tuberculosis, the child may be born with the affection fully developed. Cancer is exactly in the same state as syphilis, for children are born with fully developed cancer in the mesentery. Most of the affections that we acquire, such as small-pox, syphilis, etc.—all diseases that start as cachexia—may manifest themselves as diatheses in our children. Here is a person in perfect health who acquires tuberculosis; he has the cachexia, but will give the diathesis to his children. That point being established, let us see what can be done from a remedial standpoint.

The question that naturally presents itself is, What is the difference between a person who has the tubercular diathesis and one who has not? It is purely a chemical difference, modified by temperature, possibly. Since we know that tuberculosis is due to a peculiar seed (the *Bacillus tuberculosis*) that, falling on suitable ground, develops, so I tell you the reason it will not develop in that soil—a healthy man—is that the soil is unsuited to it. The only difference between the two is in the soil, and that difference is of a chemical nature. Plant a seed in one soil and it grows. Plant it in another and it will not grow. In the one soil there is more of this salt or another, and hence the reason for growth is that the soil is chemically suited to it. So in the body there is a chemical difference in the albuminoids that is not appreciable to us. Gentlemen, remember that this is no hypothesis and we are not guessing at it, but what I have said can be as clearly demonstrated as two and two are four. Pasteur, a man of deep thought and research in bacteriology, took agar-agar, a medium in which to cultivate germs, and added four per cent. of glycerin to it and found that the *Bacillus tuberculosis* grew beautifully, showing that it was a suited soil. He took the same agar-agar, under the same conditions, and added eight per cent. of glycerin,

and the germs would not grow in it any more than they would on this table. The two-per-cent. solution represents the child with the tubercular diathesis, while the eight-per-cent. solution represents us in whom the germs would not grow. Therefore remember these things are not spoken to you as they might have been twenty years ago, for all this can be demonstrated in a pathological laboratory. This example took place in a prepared test tube, and if it takes place here under favorable conditions of temperature and moisture, will not the same thing take place in the body? The germs of disease are different, just as the seeds of grain; and diseases are different, just as the causes that produce them. To illustrate, let me relate an incident that occurred in Paris a few years ago.

Pasteur had found a method of inoculation against splenic fever in sheep. He found that the disease would not attack fowls, but it would man. He found that when the germs were grown at the degree of temperature corresponding to the temperature of man (98·5° F.) and cattle, it was very deadly; but if raised three degrees higher, it became innocent. Then it struck him to investigate the temperature of the fowl that was 101° F. Thinking this high temperature to be the cause of his failure, he put the fowl in cold water until its temperature fell to 98·5° F., and then introduced the germ. It grew and killed the fowl, whereas before it was inert. This illustrates that temperature predisposes to disease. Two men go out hunting; their temperature is lowered; the one gets pneumonia and the other does not, because he is hearty and strong and perhaps suffered no disturbance in the body temperature.

The first one who directed our minds toward a rational treatment was Jenner, who observed the facts that led us to vaccination. What is vaccination? It is the introduction of a certain amount of chemical substance or living substance that develops in the body, and alters the chemistry of the body so that the person will not develop the disease that he would have taken otherwise. That being the case, what a great field lies before us, seeing that these affections are due to living organisms that develop and may be prevented by altering the chemical condition of the soil! What great opportunities are given to the investigation of the growth and development of germs! But, when the ways of each of these germs come to be understood; the nature of the soil and how to alter it to prevent it from growing germs—pathological germs; then will the vision of Mirza be a dream indeed. Instead of seventy arches with innumerable pitfalls and broken columns to entrap man on his way through life, there will be one hundred perfect arches over which man will travel happy and healthy to the Elysian fields beyond.

Gangrene.—The cases that I shall bring before you this morning are cases of gangrene. Gangrene is always due to some trouble in the circulation, and may be arterial, venous, or both. Arterial obstruction causes dry gangrene; venous obstruction causes moist gangrene; when due to both, we have capillary gangrene, that comes from severe bruises, old age, diseased arteries, or ergot and allied drugs. The first patient is this old woman, suffering with senile gangrene, due to the fact that her heart is too weak to carry the blood to her extremities. A few days ago I outlined on her foot, with ink, the limit between the healthy and diseased tissue, and in three days the gangrene had spread beyond this line. In a condition of this kind, where septicæmia has started, it is best to amputate far away from the diseased tissue, if the patient can stand it. I think it would be safe to amputate in this case just below the knee. Her condition was explained to her, but she refused to have any operation done, and, as a consequence, she is now laboring under a septic pneumonia from septic absorption. I think now it would be too late to operate, but, if she would consent, it would be well to do so to give her a chance for life. Gangrene starts from a cessation of the flow of blood to a part, and a focus of decomposition is started. The black condition is due to fermentation and decomposition from the presence of germs. The smell is due to sulphureted hydrogen and carbon-dioxide gas coming from the decomposing parts.

Here is another patient that had gaugreue when she came into the hospital. She had a hard fall on her buttock and the parts around the anus were very much contused and the blood supply was impaired. As a consequence, there was a sloughing, which is nothing but a condition of gangrene. The spot is limited to the extent of the injury. When this slough comes off it is called *sphacelus*. Here are healthy granulations forming, and, to facilitate the process of healing, a few sutures will be put in to draw the parts together.

The next patient is the one that I brought before you at another time when I spoke of the metastasis of cancer. I bring him in to show another case of gangrene and to operate on him. He is a young man, and we will make an effort to destroy the cancerous process if possible. You notice the gangrenous spots around this cancerous ulcer on his thigh that are due to the poison that is developing and interfering with the circulation, just as ergot, carbolic acid, and such drugs. Remember that micro-organisms may be the cause of gangrene just as they are the cause of carbuncles and anthrax. In operating on this mass, in the left groin, we must take great care not to wound the femoral artery or vein, as they will, in all probability, be exposed in cutting away this dead material. The gangrenous portions were thoroughly removed and parts dressed antiseptically. The *cure of cancer* should not be considered a hopeless aim. At the last medical congress, held in Berlin, six cases of cure of epithelioma were reported. About twenty years ago a French surgeon had a case of cancer of the breast in which he neglected to operate. As he was not cleanly and did not believe in the modern ways of treatment, the patient got erysipelas in her breast and nearly died. Fortunately, she recovered, but was seized with another attack. The cancerous growth assumed a benign appearance and an entire recovery resulted. Two surgeons in Berlin prepared pure cultures of the germs of erysipelas and inoculated a number of cancerous patients with the pure culture, and, as a result, they report the cure of six patients that were undoubtedly laboring under the cancerous process. This opens up to us a new field in the cure of cancer.

Original Communications.

A NEW THEORY ABOUT TEMPERAMENTS.*

By PAUL GIBIER, M.D.,
FORMERLY INTERNE OF PARIS HOSPITALS
AND ASSISTANT IN PATHOLOGY AT THE PARIS MUSEUM;
DIRECTOR OF THE NEW YORK PASTEUR INSTITUTE.

Great importance was attached by the ancients to the study of temperaments. In this connection it is well to observe that certain schools distinguished in special form four principal temperaments more or less susceptible of affiliation, viz., "the sanguine, the nervous, the bilious, and the lymphatic." Nowadays—while recognizing that the physiological basis varies with individuals, as is shown by the unequal distribution of maladies, or, in other words, the differences of susceptibility to infection—sufficient importance does not seem to be attached to what was formerly designated as "the composition of humors."

Were it, nevertheless, demonstrated that a difference in composition, however slight, was capable of preventing the development of certain ailments, and were it possible for the medical man to bring about such a modification in the quality of the humors of the human body, or, to use a more modern phraseology, in the chemical composition of the center of development of the germs of these ailments, would it not be of advantage in a great number of cases to know in a temperament—*i. e.*, from this our special point of view—the "composition" of a patient?

More remains to be said on this score, for if, in a curative sense, this knowledge could be utilized, how much more valuable would it not be in the preventive sense? The knowledge of a temperament once acquired, notably by the study of its ancestry—for, in my opinion, the human body inherits to a large extent the basis from which a malady takes its development rather than the malady itself—a temperament, I repeat, having been once determined, would it not be possible by an appropriately specified diet to prevent the growth of cancer, of tuberculosis, of nervous ailments, of acute or chronic rheumatism, and so forth?

Recent studies made in connection with infectious germs enable one to answer this question in the affirmative. Do we not know, for instance, that an infinitesimal proportion of chloride of silver is sufficient to check the development of certain inferior organisms (Raulin), that glycerin introduced into a culture medium otherwise inert renders it capable of giving nourishment to the *Bacillus tuberculosis* (Roux and Nocard)? Do we not, moreover, know that when we have neglected to slightly alkalinize, or at least to neutralize, an acid culture medium, the majority of pathogenic microbes decline to develop, even when but traces of acidity exist?

If it needs so little to cause an inert medium to become unfit for the development of infectious germs, what may we not expect from our cellular tissues, which are struggling actively, and I venture to say intelligently, for the preservation of their collective existence which constitutes our own as a whole?

I do not intend to dwell on this point. It is in order to place my theory on record that I make the present communication. It must necessarily be short, and I must be forgiven if what follows savors of a somewhat absolute form. I must, however, state that for the time being I merely submit my theory as a simple hypothetical one which requires confirmation, although the results obtained by me in its practical application are most satisfactory. I am fully aware that the distance between a theory of this nature and the facts to be established is great; but he who sows or plants must not look for a crop the next day.

Numerous observations made upon my patients, and experiments made both at my clinic and in my laboratory, allow me to advance the statement that there exist three temperaments or constitutions of the animal body:

1. The alkaline temperament.
2. The acid temperament.
3. The neutral temperament.

As may be observed, I am comparing the chemical composition of the animal organism to that of all other composite bodies which we study in nature.

All substances, from a chemical standpoint, are alkaline, acid, or neutral; why should not the same hold good of those living animal substances whose functions are so varied? The blood is alkaline, and yet do not the cells of the glands, the muscles, and other tissues secrete liquids that are more or less acid according to individuals? These liquids are taken up again by the blood and eliminated by the sudoriparous glands, by the kidneys, etc., or partly deposited within the organs. But the limits of this note do not allow of my carrying this point any further.

And now let us study temperaments:

1. *The Alkaline Temperament.*—People who are possessed of this temperament are but slightly or not at all predisposed to so-called arthritic affections; they have no eczema, no psoriasis, varices but seldom, and rarely any vascular or cardiac affections. They are not subject to cancer in its various forms. Their secretions are but slightly acid and they never or seldom suffer from sourness of the stomach (pyrosis). The women are more fertile.

Rheumatism, especially in the chronic form, as well as gout, is unknown among the alkaline. On the other hand, they are apt to acquire other maladies easily, and although, in case they have the chance to live far from populous centers, they may give instances of exceptional longevity, they commonly, when living in cities, show a peculiar aptitude for the acquisition of chest troubles, and more especially of pulmonary tuberculosis. This is especially the case when their means do not allow them to "acidify" themselves by indulgence in animal food. They are also subject to all forms of tuberculosis, and notably to scrofulosis.

Among the many tubercular subjects I have examined I have as yet met with none who presented, in their personal and family history, the unmistakable signs of "acidism," which I shall describe further on. Pertinent to this, I will here state that, considering, as I do, that in animal food and moderate quantities of spirituous liquors we have a

* Read before the Tenth International Medical Congress, Berlin, August, 1890.

potent means toward the acidifying of tissues, I do not hesitate to affirm that, in my opinion, a vegetarian diet (which, on the other hand, tends to alkalinize), together with a complete avoidance of fermented drinks, jeopardizes the life of alkaline subjects who live in populous centers, where the germs of tuberculous contagion are so numerous.

Among alkaline animals are the herbivora, the vaccine race especially, and it is well known how easily horned cattle become tubercular when stabled in large cities.

2. *The Acid Temperament.*—This may be observed in people who do not, any more than the alkaline subjects, present any external characteristic appearance; everything at first takes place within the body. It is but at a later period that special deformities of certain articulations, or that certain apparent cutaneous affections, may lead to their easy recognition. Yet during youth acid subjects may have facial acne. Their gastric juice is markedly acid, and more especially during adolescence they frequently complain of pyrosis. Hence, under careful hygienic direction, they are less apt than the other class, during cholera epidemics or in yellow-fever districts, to acquire these maladies; the marked acidity of their gastric juice causes the destruction of the infecting bacilli prior to their passage into the intestines.

Acid subjects are not in danger of tuberculosis or of scrofula, but, according as their peculiarity of temperament is more or less marked, they may suffer from eczema or any of the eruptions or cutaneous affections which to-day are still termed arthritic and herpetic. According to the mode of life their affections vary: the acidism may be manifested in the form of a subacute rheumatism, with repeated attacks, or of a chronic variety of this disease. A meat diet added to a liberal use of alcoholics is rapidly productive of gout in acid temperaments (more especially when exercise is not taken in order to increase the secretions) whenever heredity has, as it were, polarized the acid tendency in that direction.

It is especially among the subjects of "acidism" that we observe hæmorrhoids, varices, and the eczema of the legs which so frequently accompanies them. In these people we also find headaches (migraine) and the neuralgic affections depending upon a cellular development of the central nervous system (general paralysis, scleroses, locomotor ataxia, etc.), together with neuropathic affections, hysteria, etc.

"Acidism" would seem to develop asthma, pulmonary emphysema, chronic dry coryza, etc., in the respiratory system, while it appears to lead to aneurysms, to cerebral hæmorrhages, arterial scleroses, atheroma, angina pectoris, etc., in the circulatory apparatus.

"Acidism" constitutes a favorable soil for the development of cancer and malignant epithelial productions in general. The organs which are most frequently attacked are the stomach, a viscus whose contents are usually acid, and the uterus, which occasionally secretes an acid mucus; uterine cancer is frequently observed in nulliparæ. On the other hand, we know that acidity of the uterine mucus is a common cause of sterility.

Among the animals that are of an acid temperament we must class the carnivora (in a general manner), and particularly the dog.

It may be for this reason that the blood of this animal, when injected into the system of herbivora (which are alkaline) that have previously been inoculated with tubercular material, has appeared to retard the infection and the death of the subjects of the experiment (Richet). The dog is one of the rare domestic animals in which rheumatism may be observed.

3. *The Neutral Temperament.*—According to my theory, this would correspond to the temperate temperament of the ancients. Persons gifted with it show no marked signs belonging to the two other classes (alkaline and acid), and their state is really the normal one. They may approach either of them according to their alimentation and their mode of life. According to my observations, these people are more easily cured than the "acids" when they are attacked by certain "acidic" affections. This is equally true of the alkaline affections. This must be due to the ease with which their temperament may be modified.

Each one of these temperaments (alkaline, acid, neutral) may be met with among those whom the ancient humoralists were wont to term bilious, atrabiliary, sanguine, lymphatic, nervous, athletic, etc. These definitions describe rather the external appearance, and even the moral character, than the true temperament—that is to say, the internal constitution.

Temperaments are inherited in various degrees according to ancestors and the combinations of breeding. The marked alkaline and acid dispositions are difficult to correct and modify. The neutral, on the other hand, may be altered in either direction according to the mode of life of its possessor.

I do not wish to insist at present upon the practical deductions which may be drawn from what precedes. This will allow me to hope for a little more indulgence in case I have wandered upon a false track. It is, however, a matter that may be studied more thoroughly in time.

A CASE OF HUTCHINSON'S "VARICELLA PRURIGO."

By HERMAN GOLDENBERG, M. D.,

ATTENDING PHYSICIAN TO THE MOUNT SINAI HOSPITAL, ASSISTANT PHYSICIAN TO THE NEW YORK HOSPITAL, OUTDOOR DEPARTMENTS FOR SKIN DISEASES.

In his *Clinical Lectures on Rare Skin Diseases*, Hutchinson describes, under the name of "varicella prurigo," a disease which affects infants and children, and which he maintains to be a kind of persistent chicken-pox. The process begins as a *bona fide* varicella, the fresh crops consisting of elevated, pointed papules, feeling very firm, and each surmounted by a small vesicle.

Its peculiarity consists in that the eruption, instead of disappearing in a few days, is indefinitely prolonged by the succession of fresh crops, and that the spots ulcerate and scab, sometimes becoming large sores. The eruption is accompanied by intense itching, and may last for months or

years. He thinks the disease has nothing to do with vaccination, but considers it to be a true varicella.

I am not able to find anything in dermatological literature pertaining to this subject, except that Trousseau mentions an epidemic of varicella which occurred in the Necker Hospital, in which some cases lasted for six weeks, becoming ulcerative in character and resembling pemphigus. He does not, however, mention intense irritation as accompanying the disease.

Radcliffe Crocker also relates in his work the occurrence of cases similar to those described by Hutchinson.

Some months ago I treated a patient in the Outdoor Department of the New York Hospital (Dr. Bulkley's service), who presented the symptoms of the varicella prurigo of Hutchinson. The history given at the time was as follows:

M. L., two years old, had always been healthy. In May, 1889, she was vaccinated; the vaccination took, but was not followed by any eruption. Since August, 1889, she had suffered frequently from attacks of diarrhœa. In February, 1890, a rash appeared on the wrists and palms which resembled chicken-pox. Intense itching was the only subjective symptom, and there was no fever or general malaise. The mother, who brought the child to the dispensary, stated that a physician who saw the patient declared the eruption to be the "itch," while she and her friends regarded it as chicken-pox, the doctor's diagnosis seeming improbable on account of the lesions resembling those of varicella, and because the interdigital spaces were not affected. In the course of the following weeks the eruption appeared on the trunk and extremities, covered the entire scalp, and also affected the soles. As the lesions underwent involution and disappeared, they left scars.

There was no specific history obtainable.

The mother stated, furthermore, that there was a certain succession and regularity in the appearance of the symptoms, inasmuch as every new lesion began as a small, red, hard lump, on top of which a small vesicle appeared in the course of a few hours. Its contents were clear at the outset, but soon became purulent in character. About six hours after its appearance spontaneous rupture would occur, and a crust would form, which left a scar after it had fallen off. The itching was at its worst while the lump was present, and would diminish after the lesion became a pustule. Simultaneously with the appearance of the lesions there would be a swelling of the eyelids to such an extent that the eyes would be closed for a day, the lids having a purplish color. From the beginning of the trouble the hands were puffed.

Status præsens.—Child well developed, blue eyes, dark hair. Formation of the bones, head, and teeth perfect. On the face there were many small, slightly pigmented, depressed scars. On the left lower eyelid a small, fresh, umbilicated pustule was situated, and surrounded by a red areola. There were likewise a number of older lesions, formerly pustules, but now represented by crusts. On the back there were a great number of small, pigmented, brown spots, round and oval in shape, uniform in size, and some of them slightly depressed. The abdomen and chest were symmetrically affected, and likewise the extensor surfaces of the extremities. On these latter the pustular lesions and the scars already described were met with in abundance. The depression in the centers of these cicatrices was much more pronounced than in those on the back, nearly every single lesion showing it. The flexor surfaces of the extremities were normal. There were no new lesions on the scalp, the soles, or the palms, but a number of more or less pigmented scars indicated their former presence. There was nowhere any marked thickening of the skin. The hands were very much swollen and of a white color, the swelling being œdematous in nature, since it disappeared under pressure. Polyadenitis. The mucous membranes were normal. The urine was free of albumin and sugar.

At the second visit, three days later, there remained a pigmented, depressed scar on the site of the pustular lesion previously observed. On the forehead were a number of new, small, umbilicated pustules with a red areola, but not seated on an elevated base. The development of these pustules was, according to the mother, preceded by red, hard lumps, and accompanied by a swelling of the eyelids, in the same manner as had occurred in previous eruptions.

I impressed upon the mother the necessity of my seeing the lesions when they first appeared, and a few days later I was able to observe the process, so to speak, *in statu nascente*. The right eyelid was swollen. On the left side of the forehead there was a sharply circumscribed red lump, of the size of a marble, elevated about an eighth of an inch above the surface, movable, very firm, and painful to the touch. It was very similar to the lesion occurring in erythema nodosum. On top of this nodular lesion there was a small vesicle with clear contents. This later became an umbilicated pustule and subsequently a crust, which, when it fell off, left a depressed cicatrix. There was considerable itching while the lump was there. The latter disappeared as soon as the formation of the pustule occurred.

While under observation, the child had a number of similar attacks at different times of the day or night, and seemingly not brought on by any particular cause. The lesions were located on different parts of the body, and very itchy. Pigmented spots, and more or less pigmented, pitted scars, remained after their disappearance.

The internal treatment with tonics and arsenic in increased doses was of no benefit. Castor-oil relieved the diarrhœa and the offensive odor of the bowels for the time being. Local applications of soothing lotions and baths eased the little patient, but had likewise no marked effect on the disease. Although there was no indication for a specific treatment, I yet gave it with the same negative result. I was therefore not surprised that the mother ceased her visits, being disappointed by the inefficacy of the treatment.

In *résumé*, we had to deal with a chronic skin disease, manifesting itself in hard lesions, on top of which there developed, after a few hours' duration, small vesicles, which later became pustular and umbilicated, then crusting, and finally leaving a scar mostly resembling that of varicella. The eruption was an extremely itchy one, unaccompanied by any general disturbance, except the slight affection of the bowels. It avoided the flexor surfaces, but affected the soles, palms, the face, and extensor surfaces of the extremities. The primary hard lesion disappeared as soon as the bullous lesion became pustular.

These symptoms are exactly the same as those of Hutchinson's varicella prurigo. There may be a difference in the size of the initial lesion, as in the majority of his cases he states they were hard papules. Of some of them, however, he says himself they were like urticaria wheals.

What is it that made the celebrated English author call his disease varicella prurigo?

Let us take either of these terms separately.

As to the "varicella," it is indeed difficult to say why he affixed this term to the disease, for while on one page he regards it as a kind of persistent chicken-pox, on another

he seems to express a different opinion by saying "that it ought to be regarded as sequelæ of the exanthema" (*id est varicella*) "and not in any strict sense a continuation of it."

If the disease were a kind of persistent chicken-pox, which I shall try to prove not to be the case, there would be no reason to criticise this term; but as Hutchinson himself declares it an after-disease of the varicella, he divests himself of the right of calling it "varicella"; for we are not justified in using here the "*post hoc, ergo propter hoc*," and calling the disease varicella, because it sets in after chicken-pox, just as we do not think of calling it morbilli or scarlatina, when it appears after these diseases, as it sometimes does.

In reality the disease is not a persistent chicken-pox, and I do not speak only of my case, but I likewise include Hutchinson's cases. In going through his elaborate article, I can not help thinking that the latter have very little in common with varicella. We have a chronic disease without fever, of which the principal symptom, because it is the initial one, is the result of a transudation—that is, an œdematous swelling—whether in the form of a papule or wheal, for both are only different stages of the same process. This is a symptom we never find in varicella. I can not see why we should overlook this first and principal sign of the disease.

On the other hand, there is some resemblance to varicella, but only in the later stage of our disease—viz., when the lesions have become pustular. They then resemble those of varicella, and are indeed so much alike that the physician who sees the patient for the first time and is not informed in regard to the steps in the process will readily be deceived. No wonder, then, that mothers who are naturally unable to distinguish between the two diseases will state that a child had chicken-pox. To speak of my patient, her mother was sure that it was chicken-pox, although I know that the nodular lesions were present in the beginning in the same way as they were in the later periods of the disease. They were simply overlooked or regarded as unimportant, for the reason that they did not belong to the symptomatology of chicken-pox.

The resemblance of the pustular lesions of our disease and those of varicella is for us actually without any great importance and can not influence our diagnosis, for we find vesicular or pustular umbilicated lesions leaving more or less depressed cicatrices in several other skin diseases. They have been termed varioliform on account of the resemblance they bear to variola lesions in their clinical symptoms; but that does not make them integral parts of variola. By the same mode of reasoning, we can say also that because a lesion objectively resembles a chicken-pox lesion, it is not by any means on that account chicken-pox.

As to the scars, they are to be regarded as nothing else but sequelæ of the scratching, for I found them much more pronounced on the face and extremities than on the back. Naturally on the former surfaces the little patient had full power of her hands for scratching purposes.

In order to understand the term "prurigo," I must state that Hutchinson does not acknowledge prurigo as a disease *sui generis*. He applies this term to all diseases in which excessive itching is the first and principal feature, "whether beginning from lice, from fleas, from woolen clothing, from half-cured scabies, or from some internal cause." The name varicella prurigo is therefore meant to express varicella pruritica.

Having thus demonstrated that the process is neither varicella nor prurigo, let us now consider what the disease is:

When the individual lesions were observed, we found a papule or a wheal, precisely the same as is met with in urticaria, and this represents the primary lesion, or the one characterizing the process. During the life history of this primary lesion, however, it was seen that an inflammatory bulla, becoming later pustular, arose upon the primary wheal as a base and lasted longer than the latter. This is an occurrence which, in my opinion, must be considered as secondary and independent of the original process. Now, when, in addition to the character of the primary lesion (that is, its clinical identity with those of urticaria), we take the sudden appearance of the wheals and the excessive itching, the conclusion which I arrived at—viz., that the varicella prurigo is primarily and essentially an urticaria—is certainly justifiable, and this view I am glad to find corroborated by T. C. Fox in an article on Urticaria in Infancy and Childhood. The results of his observations agree with mine, notwithstanding that our line of reasoning was different.

But how are we to explain the bullous and pustular lesions which form on the wheals? I have already said that I considered them to be secondary to the original disease, and I can not confirm the statement made by T. C. Fox, that urticaria pustulosa is the urticaria *κατ' ἐξοχήν* of infants and children, for, according to my experience here and in Germany, pure cases of pustular urticaria are of rare occurrence; but when they are met with they are usually the result of secondary infection from without—that is, the *Staphylococcus* is brought in contact with the wheal by scratching and other means, and then a pustule appears. In my case there could be no question of the pustule being due to any external agent or cause, as there were no evidences about the primary lesions which would suggest that they had been in any way infected from without. The type was perfectly pure; each lesion was primarily a wheal, and within a very short time the further development was that of a distinct pustule, and in consequence it seemed to me that when we could exclude external infection we must look for some source of infection in the body. In my opinion, this is to be found in the fermentative processes of the intestines, which are very important ætiological factors, inasmuch as they may have a twofold effect. In the first place, they may produce wheals through reflex action; in the second place, ptomaines may be formed which, taken up by the circulation, may act as irritants upon the walls of the vessels, thus causing an inflammatory exudation into the tissues, where the wheal is situated, as there exists in that situation a *locus minoris resistentiæ*. These ptomaines may, furthermore, be pus-forming elements, and consequently the contents of the vesicle will, under those circumstances, become purulent and lose their simple serous char-

acter; for, as Brieger has shown in his elaborate work on ptomaines, the intestinal tract may be considered as a favorable location for the formation of chemical alkaloid products called ptomaines, caused under the influence of germs during the process of decomposition and of fermentation. These noxious products which are being continually formed are generally rendered harmless by the influences of certain products of digestion, such as indol, phenol, and skatol, for instance, in their chemical combination with sulphuric acid. Should the formation of these products of digestion be interfered with, owing to pathological conditions in the intestinal tract, it is evident that the influence of these noxious substances, normally produced, will no longer be controlled by their chemical antidotes.

There is one point that may seem to speak against Hutchinson's "varicella prurigo" being considered an urticaria—viz., the multiplicity of cases in one family; for Hutchinson observed in some of his cases several children of the same family affected simultaneously. One may think that this proves the contagious nature of the disease, but such is not necessarily the case. It is not uncommon to find several children of the same family affected at the same time with urticaria. This fact is not surprising considering that every one of them may be or may have been exposed to the same external or internal noxæ. In fact, this multiplicity is of such frequent occurrence that I have been asked more than once if the hives were contagious.

107 East Fifty-ninth Street.

NOTES ON AN INTERESTING CASE OF ANEURYSM.*

By GEORGE W. MAJOR, M. D.,
MONTREAL.

M. K., male, German, aged thirty-four, while walking in the street was suddenly seized with intense dyspnœa, and as he was in the vicinity of the Montreal General Hospital he made immediate application for relief. Dr. Richard L. MacDonnell, one of the physicians, was in the building at the time and admitted the man into one of his wards. As suffocation was imminent, I was summoned in consultation, and intubation of the larynx was decided upon. When I saw the patient, a few minutes after his arrival, his condition was desperate in the extreme and most painful to witness. He was unable to speak, his face was purple and swollen with blood, and he forced his finger tips into his ears in his efforts to relieve the pressure on the drum heads. I introduced an O'Dwyer tube of large size into the larynx, which afforded sensible but gradual relief. After the severity of the paroxysm had somewhat subsided I withdrew the tube, and succeeded in making a laryngoscopic examination, to which reference shall be made hereafter. When able, the patient stated that he had served in the Franco-Prussian war. He denied ever having had syphilis; had been married seven years; his wife had one child and had not miscarried. He was employed as a storeman, and was in the habit of lifting very heavy weights. He had not suffered from cough or pain in the chest. During the last two months he had several attacks of dyspnœa, but always found relief in the application of mustard. He was a large, well-built man, with a splendid development of chest, covered deeply, however, with a thick layer of fat. The pupils were of equal size, the radial pulses were equal, and there was *no tracheal tugging*.

Physical examination of the chest revealed simply diminished respiration over the left side. No dullness on percussion was at any time established, due, doubtless, to the great thickness of the thoracic walls.

The patient survived six days, and in that time was never quite free from dyspnœa. Intubation and catheterism were practiced twice during his residence in hospital, when death appeared imminent, but always with but modified relief. Finally, termination was by syncope. There was no doubt at any time existing in our minds as to the character of the case.

At the autopsy the clinical diagnosis of aneurysm was fully confirmed.

A saccular dilatation in the transverse and descending arch, about the size of a small orange, was found. The left bronchus, which passed immediately behind the sac, was almost obliterated. The rupture occurred at this point of constriction, and a number of nerve fibers connected with the pneumogastric and left recurrent laryngeal nerves were involved in the extravasation. The rupture took place into the posterior mediastinum, and there was secondary hæmorrhage into the stomach. Hæmorrhagic infarction of the pneumogastric, but particularly of the left recurrent, was observed at the post-mortem examination.

From the laryngologist's point of view, this case presents a number of interesting features and suggests a variety of considerations. Intubation did not afford the immediate and complete relief that one would expect in a case of purely glottic obstruction. The laryngoscopic examination showed the left vocal cord fixed at the middle line, left abductor paralysis with adductor spasm. The right vocal cord, though moving through its field, underwent intermittent spasmodic movements; the tendency was, however, decidedly in the direction of adduction. In this particular case the laryngeal image proved of great value as a means not only of assisting in the diagnosis of aneurysm, but also in estimating the part the larynx played in producing the dyspnœa. We might even go further and say that (taking into consideration concomitant circumstances, of course) the image was characteristic of pressure on the left vagus, or, at all events, pointed in that direction. Pressure on the vagus will produce abductor paralysis of the same side with adductor reflex spasm of the laryngeal muscles of the opposite side. In deciding these points, due allowance must be made for the stage of advancement of the aneurysm at the time of examination. If the pressure had been on the left recurrent nerve only, the vocal cord of the left side would have been affected and the dyspnœa would have been intermittent instead of having the permanent character it exhibited. Pressure on one recurrent nerve does not affect phonation and is not likely to give rise to troublesome dyspnœa; but pressure on one vagus, inducing double adductor spasm, as it does, will produce serious results thereby.

I stated a moment ago that the position of the vocal cords depended somewhat on the duration of the disease and on the amount of pressure exerted. I have occasionally observed in the course of an aneurysm that the image so varied from time to time, after a consideraole interval,

* Read before the American Laryngological Association at its twelfth annual congress.

that I was led to doubt the accuracy of a previous delineation in my register. This change is more readily observed in a case of pressure on one recurrent nerve. For instance, in recurrent pressure there may be early in the case some dyspnœa, but rarely any voice affection; on examination, we find the vocal cord on the side of pressure at the middle line—abductor paralysis. Later on the dyspnœa disappears, but the voice is impaired. The laryngoscope shows the cord of the same side at the cadaveric position—complete paralysis: the adductor fibers have become involved. The patient now suffers from phonatory leakage. He can inspire freely enough, but he can not economize his air and is easily put out of breath in consequence; his cough also is difficult; the mechanism of cough is interfered with. At a still later stage the voice may improve; this is the result not of local improvement in the case, but of the compensating action of the vocal cord of the opposite side approaching its fellow to produce vocal effect. The same state of things no doubt may occur in vagus pressure modified by the difference in the conditions. Personally, I have not had an opportunity of following vagus pressure for a sufficiently long period to speak with any authority. The late Professor Elsberg, of New York, formulated a law with the object and intention of explaining these somewhat curious facts. He maintained that "the abductor filaments of the nerve are more prone to be affected than the adductor filaments, and that if in a given case in which both the abductors and adductors are affected, recovery takes place, the adductors are apt to recover first or exclusively and to be affected with abnormal contraction, so that the patient during the progress of recovery is in danger of a dyspnœa which may necessitate a tracheotomy in order to prevent death." In practice this law has received abundant confirmation, and, in the absence of any satisfactory explanation of a theoretical nature, we can not, I think, do better than accept it.

In the case I report, the laryngeal condition was due either to pressure on the left vagus or to pressure on the recurrents of both sides. In either case great dyspnœa would be present, and in the comparative absence of physical signs it became a nice question of diagnosis. The case was not seen until pressure on the vagus had been set up, but, from the history given by the patient himself, pressure on the left recurrent laryngeal had preceded it for some months. The obstruction offered to the entrance of air into the left lung, and the altogether greater frequency of aneurysmal pressure on the left side, were valuable considerations in arriving at a correct diagnosis. In the present instance there were no physical signs of any value present excepting the pressure on the left bronchus. The laryngeal indications were therefore paramount, and, when associated with certain collateral indications, a diagnosis was not difficult. In every case of loss or impairment of voice, and in every case of dyspnœa, an expert laryngoscopic examination should be made; it no doubt would often clear up obscure symptoms and enable us to properly estimate their true value. In the course of this case there is no doubt that the attacks of dyspnœa of the greatest severity were the result of pressure exerted by the succession of hæmorrhages that took place. We have no direct proof of this, but we made tolerably certain by intubation that the larynx was not entirely at fault. The question of tracheotomy was raised at different times for the relief of the dyspnœa, but was negatived for the following reasons: In the first place, intubation failed to give the instantaneous relief it should have afforded in a case of purely laryngeal obstruction. In the second place, there was a general absence of the usual signs of laryngeal dyspnœa—for example, the larynx was stationary in the throat; it did not descend during inspiration. There was no suprasternal depression and no diaphragmatic retraction. The voice was weak, the cough and inspirations were asthenic, and the muscles of the chest were quiescent. The abdominal walls were, however, in a state of great and continued activity, especially during expiration. Had the dyspnœa been of a laryngeal nature I should not have hesitated to perform tracheotomy, not only for the relief of breathing, but also as a means of delaying the rupture of the sac.

I mentioned the absence of *tracheal tugging* in this case, and, as it is a symptom of aneurysm but little known, will say a few words concerning it before closing. Tracheal tugging was first described as a symptom of aneurysm of the arch by Dr. W. S. Oliver* (surgeon-major in H. B. M.'s regular army, retired), of Halifax, Nova Scotia. It has been recognized in the practice of the Montreal General Hospital ever since, but there has seemed to exist some doubt as to the exact way in which the "tugging" was brought about.

When the aneurysmal sac is immediately over the bronchus the direct pressure downward produces this symptom, which is synchronous with the pulse, whereas if the sac is behind or before there is no effect produced. Dr. MacDonnell, Professor of Clinical Medicine in McGill University, first gave me this explanation of the phenomenon, which I have since proved by reference to case reports. To detect this symptom the patient is placed seated upright in a chair with the mouth closed. The trachea is drawn upward by traction on the cricoid, and if "tugging" is felt you can be, in so far as my knowledge and experience goes, pretty certain of an aneurysmal sac pressing downward on the left bronchus.

The autopsy in this case was made by Dr. Wyatt Johnston, pathologist to the hospital, and my short report of the appearances was abstracted from the hospital register.

Operation for Distichiasis.—"Dr. Landolt has lately devised a new operation for this troublesome affection. He splits the lid into two portions by an incision carried right along the intermarginal space. The anterior flap contains the skin, loose tissue, and cilia, the posterior the tarsus and muscle. He then divides the anterior flap into two parts by a longitudinal incision. The lower part, which is made very small, contains the cilia. This part is shoved right up under the upper part of the anterior flap, so that it reaches to a level above or at the superior margin of the tarsus. The upper, larger part falls down by its own weight, and its edge is united to the inferior edge of the posterior flap. As soon as these two edges are firmly adherent one with the other, a longitudinal incision is carried along the eyelid at a few millimetres from the edge; and the cilia, which have till now been inclosed in a sort of pouch, are liberated."—*Glasgow Medical Journal.*

THE RAWHIDE PLATE.

A NEW PLATE FOR INTESTINAL ANASTOMOSIS.

By F. B. ROBINSON, B. S., M. D.,
TOLEDO, OHIO.
PROFESSOR OF ANATOMY AND CLINICAL SURGERY IN TOLEDO MEDICAL COLLEGE.

Very little distinct surgery of the intestines was done in a systematic method until Travers, of London, published his investigations in 1812. He entitled it *An Inquiry into the Process of Nature in repairing Injuries of the Intestines, illustrating the Treatment of Penetrating Wounds and Strangulated Hernia.* In this work Travers demonstrated remarkable tact, ingenuity, and judgment. His deductions were able and philosophical and his experiments far-reaching and practical. It was Travers who showed that a fine thread could be tightly tied around a dog's intestine, and the thread would cut through and fall into the gut lumen, while the dog would recover. The fæcal circulation would again assume its normal course. The next European experimental work on the intestines was done in France about 1825, when Jobert gave the profession his ingenious operation, and Lembert, in conjunction with Jobert, recorded the immortal Lembert stitch. Professor Czerny, of Heidelberg, a student of Billroth's, gave his stitch to the profession a few years ago. Dupuytren, Larrey, and Baudens added by practical work improvements to intestinal surgery. Ledran, Ramdohr, Denans, Reybard, Adelmann, Gegenbaur, and other Europeans recorded some experiments, but not any particular advance over Travers, Lembert, and Jobert. In America, Dr. T. Smith, of the Island of St. Croix, made a dozen experiments on dogs' intestines to test the sutures of Bell and others.

The report of Dr. Smith's experiments was published in 1805 in his Inaugural Dissertation, and placed before the trustees and faculty of the University of Pennsylvania. Dr. Smith mainly recorded the action of the operation on the animal's life, but did not give many practical views as to the nature of the pathology of repair. But autopsies then and now are different factors in medicine. Much silence reigned until 1841, when Dr. Gross, while living at Louisville, Ky., did a very notable series of experiments on seventy dogs, extending over three years. Dr. Gross did all known experiments on the intestines at that time, and deserves our lasting admiration for his courage, able execution, and commendable spirit of progress in those days of no anæsthetics.

In 1884 Professor Charles T. Parkes, of Chicago, performed a very valuable series of experiments on dogs' intestines, mainly with regard to gunshot wounds. The able work of Professor Parkes attracted widespread interest in this country. Cuts showing the results of this accomplished surgeon's experiments may be seen scattered through various surgical works, and I know personally that much good resulted to the profession from his labors.

Very little further experimental work was done to throw any light on intestinal surgery until 1887, when Professor Senn, assisted by Dr. Connell, carried out one hundred and fifty systematic experiments. In this remarkable series of experiments the brilliant genius of Senn, with his untiring energy and laudable industry, erected to his name a lasting monument of benefaction to humanity. Professor Senn's book is the best sample of the vigorous spirit of modern progress yet presented in this department of surgery. The essential idea which will be of lasting value in Professor Senn's experiments is that of anastomosis by approximating perforated discs. Professor Senn notes that Dr. Connell first suggested their use. In 1887 I began systematic experiments on the intestines of dogs, assisted by Dr. D. D. Bishop, now of Rush College. The work was continued here mainly with the aid of Dr. C. S. Miller. Dr. Gillette also shared in it. Carefully recorded work has been carried on from then until the present. We have now over one hundred and sixty systematic experiments, besides many irregular ones. As a result of these experiments, we have several new things to present to the profession. One of the new things is a rawhide plate for intestinal anastomosis.

It would be very neglectful if I did not say that Dr. Brokaw, of St. Louis, Dr. Davis, of Birmingham, Ala., and Dr. Matas, of New Orleans, have done extensive and splendid work in experiments. Dr. Davis presents the catgut mats, Dr. Matas his solid catgut ring, and Dr. Brokaw his very valuable segmented rubber ring. The advance in intestinal work is unparalleled in any age. The progress and revolutions of the past eighteen months' intestinal work are absolutely marvelous. And it still continues, for Dr. A. C. Bernays, of St. Louis, writes me, on his return from Berlin in September, that the medical men there were talking of giving up all aids to intestinal anastomosis, such as plates and rings; that they got better results from the simple Lembert suture. We hope the Lord will forgive all such sinners. This idea reminds us of Daniel Webster in Congress giving up the idea of telegraphy as a failure.

In 1889 I began to look around for a more convenient material for intestinal anastomosis than Professor Senn's decalcified perforated bone plate. His plate does the work quite well, but it requires some ten to fourteen days to prepare the plates, and they cost a dollar a pair. As the subject was then quite new, one had to rely on his own resources. At that time I had never known of cartilage being used, and, in daily passing a large butcher-shop, the non-ossified or cartilaginous part of a young beef attracted my attention. I used that with success in the form of perforated plates with four to six sutures. But I lost some dogs from too rapid absorption of the cartilage plates, so I abandoned it. For cartilage to resist absorption in the upper alimentary passage it requires a large, thick plate. For months I tried all kinds of material, chiefly leathers. The healing of the anastomosis was nearly always good, but an inabsorbable plate is a possible source of danger. Finally, to put a long, tedious number of experiments into a short story, I began the use of rawhide plates. These proved to be a remarkable success in living experiments from the simple recovery of so many of the animals. The rawhide plate is made by shaving the hair from the green hide of an ox. Then cut the hide into strips an inch wide and two inches and a half long. Perforate the plate by a diamond-shaped aperture (half an inch by three quarters of an inch). Then apply four to six sutures to the plate, armed with four to six needles, and it is ready for use. The plate can be used

dried or green. We have tried both ways many times. If the hair is shaved from the green hide and then the hide is dried, it thickens and stiffens it so that almost any kind of plates suitable to any part of the alimentary canal can be obtained. The features of these rawhide plates are—they are eminently suitable for the operation of intestinal anastomosis; they are easily prepared, quite accessible, and very convenient; they are suitably absorbable and can be well adapted to the character and quality of the intestinal tract.

After a very large number of experiments, I am fully convinced that a plate should not be absorbed too soon. One can not rely on any definite period of healing from peritoneal plastic exudates. The exudate may be rapid in its formation or much delayed. A plate should hold intact for about five days to insure success. The superiority of plates over all rings is in the amount of serous surface held in continuous approximation. Rings hold only a limited serous surface in approximation, and they are apt to contuse or cause sloughing. A plate produces equable and uniform pressure in all directions, and thus causes no sloughing or gangrene. Its edges are round and smooth, and no prominences project against the gut wall to cause gangrene of its tissues, forming fæcal fistula, and inviting the demon peritonitis to end the scene. The rawhide plates produce excellent fixation of the anastomosed parts, and consequent mechanical and physiological rest, which is required for sufficient cell proliferation and definite healing. The plate is not large or bulky, is easily inserted, and is very convenient for rapid execution—a prime necessity in all intestinal operations.

Anastomosis means the opening of one mouth into another, the communicating of one vessel with another. Intestinal anastomosis means the communicating of the lumen of one gut with the lumen of another through its walls. It is an artificial fistula in which the mucous membrane is continuous through a new channel which passes through the contiguous bowel walls. It is, in short, a bimucous fistula, which disease must have frequently been established shortly after intestines were created. Yet the idea of forming an artificial bowel fistula arose not long ago among the French. The original genius who conceived the idea did some unsuccessful operations on human beings, and the vacillating French doctors covered the poor operator with such violent storms of abuse and indelicate opposition that he dared not advocate his project or publish his writings. Curiously enough, the French were in this one thing conservative. Thus Dr. Maisonneuve's valuable conceptions lay dormant in the bowels of oblivion for years, to be acted on by a few unheeded and unnoticed progressive men, until actively revived by the bold and skillful surgeon, Dr. Hahn, of Berlin. The ground of opposition of the French medical society to intestinal anastomosis was, that fæces would accumulate in the excluded bowel loop and finally kill the patient. Our experiments, which are now over a hundred and sixty, demonstrate definitely that the fæces will not accumulate in the excluded loop, but will take the shortest route through the bimucous or artificial fistula. Experience teaches that the physiologically excluded gut will simply atrophy. Peristalsis drives the fæces out. There is a tendency in the artificial fistula to contract while healing, so that the origina incision should be liberal in size. The artificial fistula a it heals often acquires a sphincter-like condition from th periodical contraction and dilatation of the fistula, due t the irregular passage of flatus and fæces. Among the es sential elements to insure rapid union of parts in intestina operations is scarification of the serous surface coaptated We have proved often that any abraded, denuded, or ra surface in the abdominal cavity, if retained approximated will unite. It does not matter whether it is denuded mu cous or serous surface. On this principle I have a new op eration to present to the profession. It is simply the prin ciple of denuding a mucous surface and placing it in fixe approximation to a scarified serous surface. Denuded o raw surfaces heal universally. Another very important ai in the healing of intestinal wounds is the application of peritoneal or omental graft to the parts operated on. Th surface of the graft and the surface to which it is applie should be scarified with a needle point and held in positio by a few fine sutures. The grafts should be large enough t completely cover the whole wound. If the wound is ex tensive, one or more grafts could be applied. Grafts tw by four inches live well and retain remarkable vitality. Th grafts are best obtained from the omentum. Grafts ar used in two ways. One is to apply the omentum (the edg or any part) around the parts operated on, fix it in positio with sutures, and leave it unsevered from the omentum. I is not cut away from the original attachments. I have use the graft in this manner about a hundred times and neve saw a bad result. The objection to raise against it is, tha it will create an arch under which intestines will slide t and fro and may become herniated. Wandering guts ma be caught and strangulated. This may happen, but in hundred and fifty post-mortems made by myself no suc thing has been found. The autopsies were made from on to eighty days after the operation. This method of graf application is very certain in its healing, and many times have found distinct fæcal fistulæ which were arrested b the thickened graft. In these cases the graft absolutely i the means of saving life.

The other method of using peritoneal or omental graft is to completely sever them from some part of the perito næum or omentum, and then to apply them over the part operated on, fixing them in position by sutures. I have trie this method many times with success, and used grafts fro the omentum as large as three inches by five inches wit out a sign of loss of vitality. I have tried the grafts in al ways, severed and unsevered, scarified and unscarified, an am convinced that few bowel operations should be don without the application of a graft. I wish to suggest that if omental grafts are used, they should be taken from th edge (cut or torn), and not from the center or interio We did this a few times, tearing an omental graft out o the interior of the omentum, leaving a hole varying fro two inches by four inches to three inches by six inches i this membrane. The autopsy of several of those case rewarded us with very instructive information. In a cas of gastro-enterostomy an aperture was torn, and at the au topsy, weeks after, six feet to eight feet of small intestin

were found prolapsed through the hole in the omentum. The edges of the aperture had become rounded and thickened, and might strangulate the prolapsed intestines at any moment from mechanical or pathological causes.

In another case a similar occurrence was found at the autopsy when the animal was killed to obtain the specimen. The abdomen was closed by some three sutures to an inch, including skin, fascia, muscles, theca or fascia, and peritonæum. Hernia occurred in about three per cent. of the cases. But in every instance, as far as could be seen, the hernia was caused by the failure to secure the theca well (the combined fascia or aponeurosis of the oblique and transversalis abdominal muscles). I believe this is precisely the condition in the human subject. In human laparotomy, hernia is nearly always caused by the failure to secure the combined fascia or tendon of the oblique and transverse abdominal muscles well and close it with sutures. The limits of this article forbid further discussion.

The following experiments will illustrate the technique, methods, convenience, absorbability, and general use and worth of the rawhide plate, which, I hope, will be useful in future intestinal surgery. I will select at random cases of operation in different parts of the alimentary canal with the plate:

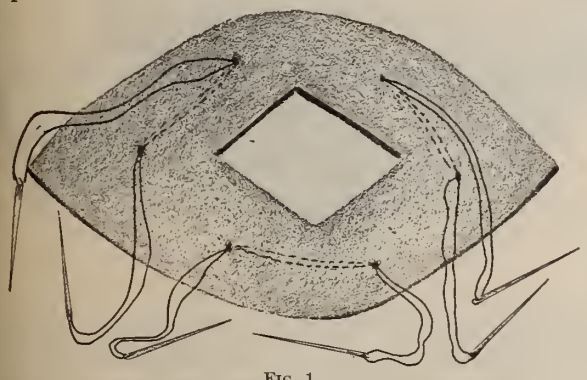

Fig. 1.

Experiment No. 18.—Dog, male; weight, twenty pounds; operation, gastro-enterostomy. In this case I used belt leather, or raw hide slightly tanned. Abdomen opened and omentum pushed to left, and loops of small intestine drawn out and incised on its convex border an inch. In this incision was inserted a rawhide plate (an inch by two inches and a half), armed with four sutures, and a needle attached to each lateral one. The two lateral needles were pushed from inside the gut outward, penetrating the entire bowel wall a third of an inch from margin of wound. An incision was made in the stomach (an inch and a half) after it was drawn out, and a plate was similarly introduced. The serous surface over the plates was scarified, and a continuous Lembert suture stitched the gut and stomach together, and, as the continuous suture coapted the scarified serous surface, the corresponding sutures on the plates were tied, first the lower lateral, then the two end ones, and finally the upper lateral one. A few over-sutures were applied. A scarified graft (omental) was applied over the scarified anastomosis and sutured in position by a few fine sutures. The dog made an uninterrupted recovery. Eighteen days after, the dog was killed. Abdominal organs found healthy. The omental graft had formed firm and strong adhesions. The anastomosis was well established. Water turned into the stomach passed equally through the new and old channel. The artificial or bimucous fistula had contracted to about half its original size. It admitted the index finger, and had the appearance and feel of a distinct sphincter. Plates entirely gone. Two threads of linen were hanging in the edge of the fistula. In approaching the stomach, instead of pushing the omentum to the left, as in securing the bowel, the great omentum was torn through, making an aperture about three inches by five inches. Through this hole some seven feet of small intestine had prolapsed. It looked very suggestive to see that roll of viscera hanging in front of the omentum, and teaches us not to make such holes or to resuture them. It would, no doubt, strangulate the intestines by some mechanical condition in the future. The plates should be kept in alcohol. The anastomosis was done four feet below the stomach. I did not intend to do that, but supposed I had the duodenum. This is dangerous, as marasmus will frequently follow from the excluded gut. The early advice of Luecke and Lauenstein, though of high authority, must be discarded. It was to seize the first appearing loop of bowel (distended). That is not justifiable, as it might be the lower end of the ileum—a mistake Lauenstein made, killing his patient in a few weeks from marasmus. To find the duodenum, introduce the index and middle fingers and feel for the pylorus, and especially the end of the pancreas, of course pushing the omentum to the left. The four feet of excluded bowel did not accumulate fæces, but assumed a condition of atrophy. Any anastomosis on the stomach should be done from its most dependent portion, so that the secretion and food can pass out with no hindrance, and also so that the continual passage of material will keep the bimucous fistula patent. This dog ate voraciously, but lost flesh. Our experiments demonstrated that the physiological exclusion of four feet of bowel was often followed by marasmus.

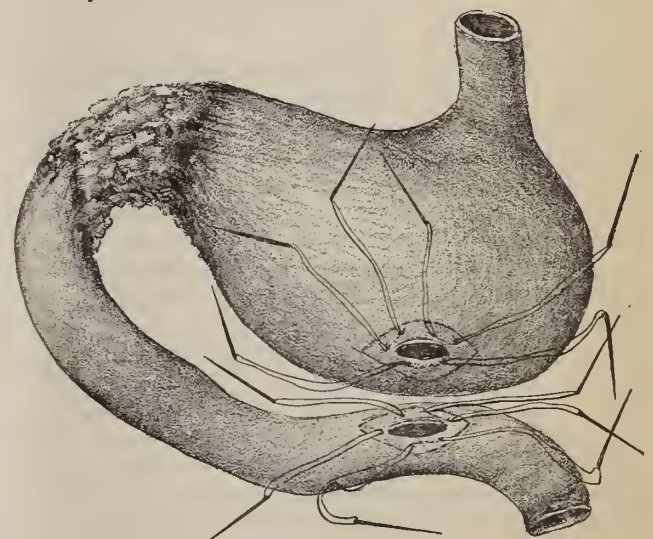

Fig. 2.

Experiment No. 24.—Dog, male; weight, twenty pounds; operation, gastro-colostomy; material, rawhide plates. The intention was to anastomose the colon (transverse) to the stomach. The stomach incision was an inch and a half, and the bowel an inch long. The plates were inserted, and the lateral needles pushed from within outward, the serous surface was scarified, the plates were placed *vis à vis*, and the corresponding sutures were tied—first the lower, then the end, and finally the upper. No Lembert sutures employed, and no graft. Time of operation, twenty minutes. Dog made a good recovery. He was chloroformed to death in eleven days. Autopsy showed all abdominal organs healthy. The autopsy also showed that the transverse colon was not disturbed, but the rectum was anastomosed to the stomach. Hence the dog had

just enough stomach and gut to reach from mouth to anus for an alimentary canal. It dragged and dilated the stomach about a quarter larger than normal. Water turned into the stomach passed almost entirely through the new artificial fistula, which had contracted to half its original size, and felt precisely like a natural sphincter. It admitted the index finger. Though the dog had nearly all the bowels excluded physiologically, he did not have marasmus. The plates were entirely absorbed. No fæcal accumulation occurred in the excluded bowels. Without large practice, one can not seize the bowel at a desired point unless eventration is resorted to, passing the bowel before the eye and through the fingers.

Professor Madelung, of Rostock, made crucial tests to show the difficulty of diagnosis of points of the intestines which are familiar to most abdominal surgeons. They demonstrate that practice alone insures accuracy in diagnosticating disease of the intestines.

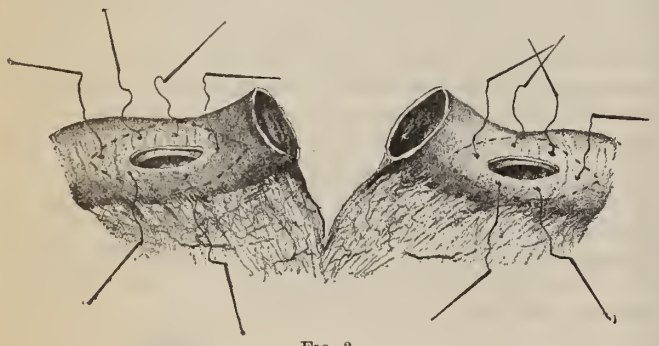

Fig. 3.

Experiment No. 22.—Dog, female, weight fifteen pounds. Operation, ileo-ileostomy; material, rawhide plates; animal chloroformed, belly shaved, and through a two-inch abdominal incision a loop of small intestine was drawn out along the right side of the omentum. The bowel was completely severed and its two ends invaginated each an inch and held in position by four to six continuous Lembert sutures. On the convex surface of each gut (the part most distant from the mesentery) incisions an inch long were made. Rawhide plates (an inch by two inches and a half) were inserted in the bowel. The six needles armed with linen sutures were passed from the inside of the gut lumen through the entire bowel wall one third of an inch from wound margin. The serous surface over the plates was scarified with a needle point, the plates were approximated, and the six corresponding sutures were tied. A few continuous over-sutures were added. An unsevered omental graft was applied to the anastomosis and held in position by four fine sutures. Ten inches of the ileum was excluded. Dog recovered excellently, ate, drank, played, and appeared happy. She had slight marasmus. She was chloroformed to death fifteen days after. The autopsy showed healthy viscera. A very circumscribed local peritonitis had arisen and subsided. The graft was solidly and firmly grown to the parts. The severed gut ends were well healed, but one had continued to invaginate two inches and the other an inch and a half. This is a danger I have frequently observed, but have never found it recorded by other writers. I have lost eight to ten dogs from this cause. The invagination continues, and it finally mechanically occludes the gut lumen or the artificial fistula. The plates were entirely absorbed. In the absence of hydrogen gas at the autopsy I filled a four-gallon rubber balloon with air and inserted its nozzle into the rectum. The abdominal wall was then removed. Slight pressure on the balloon soon forced the gas with an audible noise through Bauhin's valve, through the pylorus, and out at the nose. The anastomosis did not leak. If, however, one attempts to force the air or gas from mouth to rectum, it will generally rupture or lacerate the tissues, especially the peritonæum.

Experiment No. 40.—Dog, male, weight twelve pounds. Operation, ileo ileostomy; material, green, soft rawhide plates. A loop of intestine was drawn out and anastomosed. No over-sutures, but an unsevered omental graft was well applied over the parts and sutured in position. As dogs were occasionally scarce, we operated several times on the same one at different dates, so, nine days after, circular enterorrhaphy was performed on this dog. He did well, ate, drank, and played. Twenty two days after the first and nine after the second operation the dog was killed. The organs were found healthy at the autopsy. Two points showed the rise and subsidence of a local peritonitis at the enterorrhaphy and anastomosis. The graft had healed; it was strong and firm. The anastomosis was well established, conducting nearly all of the fæcal circulation. The artificial fistula had contracted to half its size and was distinctly sphincter-like. The fistula is generally larger when *all* the fæces and flatus are compelled to go through it. Here it had two routes. Rawhide plates entirely absorbed. All the sutures (six) were still hanging in the edge of the artificial fistula. The circular enterorrhaphy had contracted to a third of its original size and was beginning to cause obstruction.

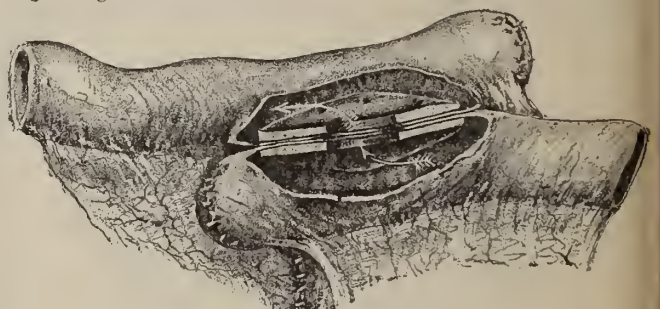

Fig. 4.

Experiment No. 66.—Dog, male, weight twenty-five pounds. The usual preparations and a loop of intestine drawn out. Ten inches was resected. The two divided ends were invaginated an inch, and so sutured in position with six continued Lembert sutures. Rawhide plates were introduced into the incisions in the bowel and approximated and tied. A graft was applied over the parts and sutured in position. The dog made an uninterrupted recovery, ate, drank, and played. He escaped, unfortunately, on the ninth day, hale and hearty.

Experiment No. 67.—Dog, male, weight ten pounds. Operation, resection of an inch and a half of bowel, and canal restored by anastomosis with rawhide plates. After the resection the two bowel ends were invaginated an inch each and sutured in position, then anastomosed. Graft applied. The rawhide plates were very thin. The dog was killed on the ninth day. Graft was well healed, anastomosis well established, and artificial fistula of good size. Plates entirely absorbed. A very important point was again observed in regard to the invaginated bowel ends which had proceeded beyond the point of the artificial fistula, causing danger of mechanical obstruction at any moment. What is to be done to avoid it? Invaginate only half an inch, so that the muscles of the gut do not get any purchase power in peristalsis.

Experiment No. 43.—Dog, male, weight forty pounds. The dog's intestine was drawn out and invaginated four inches by forcing the upper segment of the bowel into the lower or drawing the lower over the upper. The invagination was sutured in position by four sutures; belly closed. Forty-eight hours after, abdomen reopened. The gut had so violently disinvagi-

nated itself that it had torn out two sutures and insinuated itself out between the other two. The whole disinvaginated loop was excluded by anastomosing the gut above to the gut below with rawhide plates (green and soft). Graft applied. Dog died nine days after from progressive fibrino-purulent peritonitis. The peritonæum showed at the autopsy a wonderful variety of pathology—pyogenic membrane, pus puddles which Nature had tried to hem in, and local fields of tortuous impacted blood-vessels meandering like golden threads over dusky mottled membrane. The excluded gut was contracted and only had a little mucus left in it. Two invagination sutures still existed in the bowel. The anastomosis was well established and the artificial fistula was large. No sign or trace of the plates was seen. The graft was solidly and firmly healed. The dog was killed by infection at one of the operations.

Experiment (not numbered).—Dog, male pup, weight eight pounds. Operation, ileo-ileostomy; material, rawhide plates, very thin. A loop of intestine was drawn out, and, through incisions in the bowel, the plates were inserted, coaptated, and tied. The dog ate, drank, and played the next day, and continued in this manner until he was killed, two weeks later. Autopsy: Abdominal organs healthy. Graft well grown. Anastomosis established; but here again the fæcal circulation had two directions to travel, and hence the artificial fistula was small. Plates entirely gone.

Many more examples might be adduced out of over a hundred and sixty experiments, but, no doubt, sufficient have been given. The cuts will illustrate the technique and methods of using the plates.

THE RELATION OF GONORRHŒA TO RENAL DISEASE.

By JAMES KENNEDY, M. D.,
SAN ANTONIO, TEXAS.

In a case of urethral stricture where I performed the operation of external urethrotomy the patient died within five hours, and post-mortem examination revealed the existence of a chronic suppurative nephritis. The patient having given a history of gonorrhœal infection, followed by gleet and subsequent interference with micturition, the inquiry naturally suggested was, What relation did the gonorrhœal infection bear to the renal lesion?

The history of the case in which I operated is briefly as follows:

The patient, who was thirty-eight years of age, had contracted gonorrhœa some two or three years previously, had used various injections, and, after several months of this self-treatment, considered himself cured.

Within the past year he had experienced pain in the region of the bladder, and had noticed that his urine would often be of an unnatural appearance, being sometimes milky, and experienced considerable difficulty and often pain in emptying the bladder. But only within the past month did he deem it necessary to send for a physician, and then only because of the urgency of his symptoms, being unable to empty his bladder, and, in consequence of the overdistention, suffered intense pain.

I attempted to relieve his condition by means of a flexible catheter, but found it would not pass the deeper stricture (there being two). I then resorted to a metallic instrument, and succeeded in emptying his bladder of its foul contents, which consisted of decomposed urine, pus, and blood.

I believed from the history and symptomatology that I was dealing with a bad case of chronic cystitis, and that relief, if any was to be obtained, must be found in the creation of an artificial urethra and the removal of the stricture by means of an external urethrotomy, which, in addition to draining the bladder, would also enable us to wash it out with antiseptic solutions, by which means I hoped to arrest the inflammatory process and ameliorate the patient's condition.

In reference to the operation I need only say that I operated according to the usual method, and, after an opening had been made into the urethra, a cannula was introduced. Chloroform was used as an anæsthetic, and the operation completed in ten minutes. The patient rapidly recovered from the anæsthesia and was not unconscious more than twenty minutes.

I left him at 12 M., and instructed to give him stimulants in moderate quantity. When I returned at 5 P. M. his pulse was feeble and so rapid that it could not be counted. On examination, I found that no urine had passed through the cannula, and suspected some obstruction in the instrument. This proved to be not the case, however, for, on removing the instrument and exploring with the finger, the bladder was found empty. There was acute suppression of the renal function.

The pulse grew more feeble and more rapid, and respiration became labored and interrupted. I administered whisky hypodermatically, but to no avail. I sent for digitalis, but the patient sank rapidly and died before it arrived.

Post-mortem.—The bladder showed evidence of chronic inflammation, being four or five times its normal thickness. The ureters showed similar evidence of having participated in the inflammatory process.

The kidneys were about three times their normal size, and, on section, exhibited a number of abscesses of various sizes, some containing as much as two or three drachms of thick, greenish-yellow pus. Each abscess had a distinct wall of considerable thickness, and many of them communicated.

These organs were literally nothing more than suppurating masses of tissue, and how they managed to perform their important functions in their extremely disabled condition, as they had been doing for months, I do not understand.

Relation between Gonorrhœa and Renal Disease.—There is no doubt in my mind that if this patient had not contracted gonorrhœa he would not have died of suppurative nephritis. I believe that gonorrhœa is a frequent causative factor in renal disease, and that among the sequelæ of this lesion nephritis is not rare.

The ways in which gonorrhœa may induce disease of the kidneys appear to me to be as follows:

1. By direct extension of the inflammatory process by virtue of continuity of structure.

2. By interference with escape of urine, as in stricture. The bladder, becoming filled, causes the urine to collect in the pelvis, calyces, and tubules of the kidney, and interferes with the process of secretion, causing congestion, which, if prolonged, the succeeding stages of inflammation follow and a nephritis is established.

3. By reflex irritation. The urethral irritation may reflexly disturb the renal function and cause hyperæmia and congestion.

4. By diuretics. The excessive or injudicious administration of copaiba, cubebs, etc., so commonly used for the cure of gonorrhœa, may induce disease of the kidneys by overstimulation of these organs.

NEW YORK, SATURDAY, OCTOBER 18, 1890.

PAWLIK'S OPERATION FOR CANCER OF THE CERVIX UTERI.

The *Medical News* gives an interesting estimate of Pawlik's recently proposed operation for the free extirpation, by the vaginal method, of the neck of the uterus when cancerously diseased, and of the perimetric connective tissue along with the diseased part of the uterus. This procedure is dignified by the somewhat ambitious, possibly misleading, title of "the radical cure of cancer of the cervix uteri." The "radical" feature consists in the free use of the knife upon those lateral tissues in which the disease usually spreads before it extends from the cervix to the body of the organ. Incidental to this operation are Pawlik's studies in regard to catheterism of the ureters, which confirm the view already pronounced by that surgeon that the free removal of the infiltrated tissues may be accomplished without injuring the ureters. This confirmation has been found, the writer believes, in the fact that the ureters are rarely involved in the cancerous infiltration. In four cases of cancer of the cervix he inserted a catheter into the ureters and proceeded to remove the diseased organ and its adjacent connective tissue. The results thus far obtained appear to justify the inductions; two of the patients are now alive and without a recurrence of the trouble, a year and more having elapsed since the operation; in a third case cystitis with uretero-vaginal fistula has been an unfortunate sequel, but the patient's general health has continued good. One patient has passed out of observation and can not at present be reported on.

This is a small series of cases upon which to build any broad generalizations, but we are confident that it will enlist the attention of surgeons. The writer in the *News* has evidently been under the immediate influence of Pawlik, since that part of his article which relates to catheterism of the ureters reveals the fact that "under his eye we have successfully followed his example" in regard to the delicate manipulation. He therefore writes with a full appreciation of the requisites of the operation under discussion. Catheterism of the ureters, while not exceedingly difficult, requires constant practice, and Pawlik himself embraces every opportunity to practice this exploration, for he finds that only in that way can he maintain his remarkable dexterity. It is evident from this that the average operator may not at once succeed in following his example. Without a guide in the ureter it would certainly be unsafe to attempt the radical removal of connective tissue surrounding the diseased cervix, and impossible to determine whether the ureters were not themselves involved in the disease. To one who has diligently built himself up in manipulations of this delicacy this so-called radical cure will appear worthy of a trial, whereas the less expert and dexterous will approach the practice with diffidence. The class of cases to which it will probably be found best applicable will be those in which the perimetric tissue is only partially invaded, as shown by a remaining mobility of the uterus, and in which the disease has not extended to the fundus; in other words, the early employment of the operation will give the greatest promise of success.

THE ADIRONDACK SANITARIUM.

This institution, at Saranac Lake village, has now reached such a point of popular approval and grateful recognition that gifts begin to flow in upon it, and its permanent endowment may be looked forward to as a very probable event. Dr. Trudeau is no longer alone there as attending physician, but is now assisted by Dr. C. F. Wicker. The present accommodations are for fifty patients, but two new cottages are now being built, which, with other proposed changes, will make them sufficient for about sixty; as it is, the room is all taken up, and applicants are awaiting their turn as vacancies occur. A benevolent New York lady has given the means necessary to the erection of a recreation hall, or pavilion, which will contain billiard tables and other apparatus for gentle exercise in inclement weather; also about it there will be promenades which can be shut in with glass when the midwinter cold prevents the patients from going into the open air to the same extent as in other seasons. There are a few free beds for recommended patients, for the benefit of those who can not defray the almost nominal charge of five dollars a week. The cottages are small, being commonly designed to hold not more than from two to five beds. Out-of-door life being one of the cardinal principles of the Adirondack regimen, facilities are provided for riding, walking, and other suitable diversions. In regard to admissions, it is the aim of Dr. Trudeau to restrict them to cases of phthisis in its incipient stage and to persons of the *res angusta domi* type, and thus to restore to their occupations the productive and industrious members of society; he thus acts on the principle that Mr. Jonathan Hutchinson has given recent expression to as being the fundamental idea of the modern hospital—namely, that it is an institution for the prevention of orphanage. No single generation measures the bounds of influence for good of the modern institutions of charity. Dr. Trudeau himself and some of his most interested supporters have been restored to health and useful activity by the Adirondack air and regimen, and they know the extent as well as the limitations that pertain to the work they have so carefully and beneficently undertaken.

KOCH'S BERLIN ADDRESS.

The statements made by Koch in his notable address at the Berlin Congress have received confirmation in two important points. To one of these we have already referred—namely, to the work done by Grancher and Martin, of Paris, in the production and arrest of inoculated tuberculosis in rabbits. This work is confirmatory of Koch's experiments on the guinea-pig, with

an agent not yet named, for the reason that the series is yet incomplete and under observation. The second point wherein Koch's observations have been corroborated is that regarding the antitubercular properties of gold and silver compounds. This we learn from an article in the *Lancet* for August 30th, which describes the almost synchronous discovery of an Austrian official in regard to the apparent prevention of phthisis among workmen who have to handle and work with "cyan-gold." This observer, Herr Reuter, read a paper in April last before the Industrial Union of Lower Austria, showing how his position as director of several great workshops of metallic wares, at home and abroad, had led him to notice the relative infreqnency of consumption among his operatives, and to become inquisitive as to the agencies at work among this class of workmen. He paid particular attention to works in which the artisans were engaged in galvanizing articles with gold and silver, and the inquiries that were made by him gave him the impression that a healing virtue resided in prussic acid, the use of which is essential in those workshops where the "cyan-metals" dissolved in potassium cyanide are used. Herr Renter obtained much confirmatory testimony from the workmen in these works. Not only did they agree that consnmption was extremely rare among them, but that many of those who came into the works from other places, and who had diseases of the respiratory organs, were greatly benefited, and some entirely cured. Since the adjonrnment of the Berlin Congress, the Vienna Medical Association has begun the consideration of Herr Renter's observations, and has already indicated that they appear to be reliable and valuable.

We commend to our readers a full perusal of Koch's great paper, for, if we mistake not, it will hereafter take rank with the epoch-making essays of Harvey, Boerhaave, Hunter, Jenner, and Pasteur. It is too early yet to know positively facts which Koch himself announces apologetically and in part only; still it is a significant and hopeful sign that, almost immediately upon the adjournment of the great Congress, there should come from different sources, and with different ends in view, these various voluntary confirmations.

MINOR PARAGRAPHS.

RUPTURE OF THE VAGINA.

Dr. Himmelfarb, of Odessa, and others are quoted in the *British Medical Journal* regarding the causation of this injury. He has carefully studied the literature of this comparatively unexplored subject, and presents cases of his own. He concludes that, while the major part of the cases reported have been an accident of parturition, there are some cases that have been due to the introduction of foreign bodies and to violent coitus. The last-named cause is not always acknowledged when it should be. The rupture of the vagina of old subjects during coitus is a well-recognized injury. When the accident occurs in young subjects the explanation of its production becomes more difficult. Dr. Himmelfarb reports a case in a healthy woman, aged twenty-four, in whose person the posterior wall of the vagina was torn through during coitus, and in whom the rupture was followed by parametritis, peritonitis, and fatal pyæmia. Connection had frequently taken place, after the first occasion when the pain was very severe, notwithstanding the suffering that it produced. Dr. Himmelfarb thinks that vaginal rupture is more frequent than is commonly supposed in those cases of sudden pain from coitus where no sign of injury to the external parts exists, and that coitus is then the true cause of the injury. Dr. Frank, of Prague, has reported a case of rupture where there was a double vagina. The right half ended in a blind sac, while the left communicated with the uterus; the hymen on the right side and the septum were lacerated in coitus. He has also had a case of extensive laceration in a woman aged thirty-two. She recovered from the injury, which was certainly inflicted during connection. The entire subject is not without medico-legal interest and importance.

TRICHLORACETIC ACID IN THROAT DISEASES.

The testimony in favor of the use of trichloracetic acid in diseases of the throat is accumulating. In the *Lancet*, Ehrmann, of Heidelberg, is quoted in reference to his results in over a hundred recent trials. In one hundred and forty cases of chronic inflammation and of hypertrophic conditions of the various parts in the neighborhood of the pharynx and nares this remedy was employed with marked success. In one hundred and twenty-two cases he reports permanent cure. The method of its employment is twofold—as an escharotic and as an astringent. Hypertrophied tonsils and other parts may be reduced by rubbing them with a crystal of the acid, which has the effect of producing an eschar that is white, dry, smooth, and adherent. This eschar is thrown off much more slowly than that produced by chromic acid. Ehrmann observed no secondary inflammation or other unpleasant effects of any kind. If a merely astringent effect is desired, the acid should be dissolved in an equal weight of glycerin (or in double its weight), with the addition of a little iodine and iodide of potassium, and the mixture may be used to paint the throat with. The best results were obtained in follicular amygdalitis and chronic pharyngitis. At the last meeting of the New York State Medical Association, Fifth District Branch, Dr. Gleitsmann, of New York, reported that he had been pleased with the apparent results in the treatment of tonsillar disease with the acid, and that it was his purpose to extend his employment of the drug. In regard to the handling of the crystals of the acid, Ehrmann has found that a silver applicator which will hold the crystal firmly answers a very good purpose.

THE MURDER OF DR. LLOYD, OF FLATBUSH.

Dr. George W. Lloyd, assistant superintendent of the Kings County Asylum at Flatbush, has been murdered by a discharged lunatic, who was at the time in pursuit of the superintendent, Dr. Fleming. This took place on the evening of Thursday, the 9th instant. The murderer has declared that he had had no feeling of special animosity against Dr. Lloyd personally, but was actuated by a revengeful rage against all who had been instrumental in his former confinement, from the judge down to the subordinate attendants. Both Dr. Arnold and Dr. Fleming probably had a narrow escape from the same fate, since the maniac was armed with two fully loaded revolvers, and was in search of them when Dr. Lloyd was encountered and slain, a guiltless martyr, while engaged in the round of his professional duty. Dr. Lloyd was a painstaking and efficient official. The obvious reason why he was slain was that the men marked out for slaughter were not found conveniently at hand in the places of their customary resort, but the real reason was that somebody had blundered in allowing a violent lunatic to remain at large.

THE INDIGENT INSANE OF THE STATE OF NEW YORK.

It was to be expected that the State Commission in Lunacy would take all necessary measures for properly administering the new law committing the indigent insane to the care of the State, but it is none the less gratifying to meet with tangible evidence of the commission's activity. Elsewhere we publish the order issued by the president, Dr. Carlos F. MacDonald, regarding the transportation of the insane poor to the State hospitals, and we will mention an order by the commission to the effect that hereafter private patients in the State hospitals are not to be treated differently from public patients in respect to the care and accommodations furnished them.

THE CONVICTION OF AN ABORTIONIST.

The prompt conviction of Dr. McGonegal on the charge of having caused a young woman's death by criminal abortion, and his sentence to imprisonment for fourteen years, are reassuring signs that the machinery of the courts is not wholly untrustworthy as a means of curbing a crime that too often goes unpunished. Their significance is tempered, however, when we reflect that it was not so much the crime itself that seemed to be presented to the jury as the peculiarly heartless way in which the accused was shown to have carried out his measures.

A RUSSIAN INSTITUTE OF BACTERIOLOGY.

It is announced that a Pasteurian Institute is to be established at St. Petersburg, through the generosity of Prince Peter Oldenbourg. The building, on Apothecary Island, is nearly completed, and will be known as the Institute of Experimental Medicine. The conduct of the studies in regard to rabies and contagious diseases generally will be intrusted to specialists in bacteriology, chemistry, biology, and veterinary science.

"SUNDOWN DOCTORS."

This is the appellation said to be applied in the city of Washington to a class of practitioners who are clerks in the Government offices, and who have taken a medical degree with a view to practicing after the hours of their official work are over.

A MISSIONARY HOSPITAL IN SITKA.

Dr. Clarence Thwing, of Brooklyn, has accepted an invitation to establish one or more missionary hospitals in Alaska, beginning at Sitka. He was graduated about three years ago, since which time he has been engaged in special courses that will fit him for his new and responsible berth. His father, also a physician and a clergyman as well, has become known through his advocacy of the establishment at Hong Kong of an asylum for the insane, which, if he succeeds, will be the first of its kind on Chinese soil.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 14, 1890:

DISEASES.	Week ending Oct. 7.		Week ending Oct. 14.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	39	3	45	16
Scarlet fever	28	1	25	5
Cerebro-spinal meningitis	2	2	0	0
Measles	43	4	79	6
Diphtheria	57	13	46	15

Alleged Danger in Artificial Celluloid Eyes.—"Dr. Meurer, of Lyons, warns physicians against the use of artificial eyes made of celluloid. They are cheap and of good appearance, and for the first three or four months render good service. After this, however, they undergo chemical changes, and set up a high degree of irritation. Meurer has repeatedly overcome the resultant inflammation by antiseptic treatment and suspending the use of the artificial eye. So soon as the old eye was again used the inflammation returned, but on using a glass eye the parts remained normal."—*Druggist's Circular and Chemical Gazette.*

Change of Address.—Dr. P. Flewellen Chambers, to No. 26 West Forty-seventh Street.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 27 to October 11, 1890:*

Phillips, John L., Captain and Assistant Surgeon. By direction of the Secretary of War, the leave of absence granted in S. O. 164, July 16, 1890, from this office, is extended two months. Par. 3, S. O. 228, A. G. O., Washington, September 29, 1890.

Owen, W. O., Jr., Captain and Assistant Surgeon, in view of the abandonment of Fort Gibson, Indian Territory, to which post he is at present assigned for station, is relieved from duty at that post, and will, upon the expiration of his present leave of absence, proceed to Fort Sill, Indian Territory, and report to the commanding officer for duty. S. O. 155, Department of the Missouri, September 27, 1890.

Phillips, J. L., Captain and Assistant Surgeon, in view of the abandonment of Fort Crawford, Colorado, to which post he is at present assigned for station, is relieved from duty at that post, and will, upon the expiration of his present leave of absence, proceed to Fort Logan, Colorado, and report to the commanding officer for duty. Par. 4, S. O. 155, Department of the Missouri, September 27, 1890.

Tesson, Louis S., Captain and Assistant Surgeon, Fort Sidney, Nebraska. Leave of absence for twenty days, to take effect when his services can be spared by his post commander, is granted. S. O. 72, Department of the Platte, September 25, 1890.

Crampton, Louis W., Captain and Assistant Surgeon (Fort Sheridan, Illinois). Leave of absence for one month, to take effect about October 1, 1890, is granted. Par. 2, S. O. 80, Division of the Missouri, September 30, 1890.

Byrne, Charles C., Lieutenant-Colonel and Surgeon, is relieved from duty as attending surgeon at the Soldiers' Home, near this city, and will report in person to the commanding officer, Fort Sam Houston, Texas, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Baily, Joseph C., Lieutenant-Colonel and Assistant Medical Purveyor, Medical Director of the Department, is granted leave of absence for one month. Par. 3, S. O. 86, Department of Texas, October 3, 1890.

Reed, Walter, Captain and Assistant Surgeon, is, by direction of the Secretary of War, relieved from further duty at Mount Vernon Barracks, Alabama, and assigned to duty as Attending Surgeon and Examiner of Recruits at Baltimore, Md. Par. 7, S. O. 233, A. G. O., Washington, D. C., October 4, 1890.

Gibson, Robert J., Captain and Assistant Surgeon, is, by direction of the Secretary of War, granted leave of absence for three months, to take effect on being relieved from duty at Fort Trumbull, Connecticut, by Major Henry M. Cronkhite, Surgeon. Par. 12, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Macauley, C. N. Berkeley, Captain and Assistant Surgeon, is, by direction of the Secretary of War, relieved from duty at Fort Supply, Indian Territory, and will report in person to the commanding officer, Fort Lewis, Colorado, for duty at that station. Par. 2, S. O. 233, A. G. O., Washington, D. C., October 4, 1890.

Benham, Robert B., Captain and Assistant Surgeon, will, by direction of the Secretary of War, proceed from Fort Hamilton, New York, to Mount Vernon Barracks, Alabama, and report in person to the commanding officer of that post for temporary duty, relieving Cap-

tain John J. Cochran, Assistant Surgeon, who will return to his proper station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Ebert, Rudolph G., Captain and Assistant Surgeon, is, by direction of the Secretary of War, relieved from duty at Angel Island, California, to take effect upon the arrival at that post of Major William H. Gardner, Surgeon, and will then proceed to Vancouver Barracks, Washington, and report for duty to the commanding officer of that post for duty. Par. 15, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Gardner, William H., Major and Surgeon, is, by direction of the Secretary of War, relieved from duty at Washington Barracks, D. C., to take effect on the arrival of Major Joseph K. Corson, Surgeon, and will report in person to the commanding officer, Angel Island, California, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Wood, Leonard, First Lieutenant and Assistant Surgeon. The leave of absence granted in S. O. 74, August 30, 1890, Department of California, is, by direction of the Secretary of War, extended one month. Par. 7, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Hubbard, Van Buren, Major and Surgeon, is, by direction of the Secretary of War, relieved from duty at Columbus Barracks, Ohio, and will report in person to the commanding officer, Fort Spokane, Washington, for duty at that station, relieving Captain Henry S. Purrill, Assistant Surgeon. Captain Purrill, on being relieved by Major Hubbard, will report in person to the commanding officer, Madison Barracks, New York, for duty at that station, relieving Major John D. Hall, Surgeon. Major Hall, on being relieved by Captain Purrill, will report in person to the commanding officer, Fort Canby, Washington, for duty at that station. Par. 8, S. O., 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, the following changes in the stations and duties of officers of the Medical Department are ordered:

Sternberg, George M., Major and Surgeon, is relieved from duty as Attending Surgeon and Examiner of Recruits at Baltimore, Md., and as a member of the Army Medical Board appointed to meet in New York city, N. Y., and will repair to San Francisco, Cal., and take charge of the Medical Purveying Depot at that place, as Acting Assistant Medical Purveyor, relieving Colonel B. J. D. Irwin, Surgeon. Colonel Irwin, on being thus relieved, will report in person to the commanding general, Department of the Columbia, for assignment to duty as Medical Director of that department and as Post Surgeon, Vancouver Barracks, Washington, relieving Major William E. Waters, Surgeon, now Post Surgeon, and temporarily in charge of the Medical Director's office. Major Waters, on being thus relieved, will report in person to the commanding officer, Fort Custer, Montana, for duty at that station. Par. 8, S. O. 232, A. G. O., October 3, 1890.

Munn, Curtis E., Major and Surgeon, is, by direction of the Secretary of War, relieved from duty at Angel Island, California, and will report in person to the commanding officer, Fort Monroe, Virginia, for duty at that station, relieving Major John Brooke, Surgeon. Major Brooke, on being relieved by Major Munn, will report in person to the commanding officer, Fort Leavenworth, Kansas, for duty at that station, relieving Major Alfred A. Woodhull, Surgeon. Major Woodhull, on being relieved by Major Brooke, will report in person to the commanding officer, Fort Sherman, Idaho, for duty at that station. Par 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Borden, William C., Captain and Assistant Surgeon, is, by direction of the Secretary of War, relieved from duty at Fort Sam Houston, Texas, upon the arrival of Lieutenant-Colonel C. C. Byrne, Surgeon, and will report in person to the commanding officer, Fort Davis, Texas, for duty at that station, relieving Captain Peter R. Egan, Assistant Surgeon. Captain Egan, on being relieved by Captain Borden, will report in person to the commanding officer, Fort Warren, Massachusetts, for duty at that station, relieviug Captain George McCreery, Assistant Surgeon. Captain McCreery, on being relieved by Captain Egan, will report in person to the commanding officer, Fort Clark, Texas, for duty at that station, relieving Captain Charles M. Gandy, Assistant Surgeon. Captain Gandy, on being relieved by Captain McCreery, will report in person to the commanding officer, Fort Shaw, Montana, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Finley, James A., Captain and Assistant Surgeon, is, by direction of the Secretary of War, relieved from duty at Fort Totten, North Dakota, and will report in person to the commanding officer, Jefferson Barracks, Missouri, for duty at that station, relieving Captain William D. Crosby, Assistant Surgeon. Captain Crosby, on being relieved by Captain Finley, will report in person to the commanding officer, Fort Pembina, North Dakota, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Taylor, Arthur W., Captain and Assistant Surgeon, is, by direction of the Secretary, relieved from duty at Fort Wingate, New Mexico, to take effect on the expiration of his present sick leave of absence, and will report in person to the commanding officer, Fort Adams, Rhode Island, for duty at that station, relieving Captain J. J. Cochran, Assistant Surgeon. Captain Cochran, on being relieved by Captain Taylor, will report in person to the commanding officer, Camp Eagle Pass, Texas, for duty at that station, relieving First Lieutenant Paul Clendenin, Assistant Surgeon. Lieutenant Clendenin, on being relieved by Captain Cochran, will report in person to the commanding officer, Fort Brady, Michigan, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Smith, Allen M., First Lieutenant and Assistant Surgeon, is, by direction of the Secretary of War, relieved from duty at Fort Snelling, Minn., and will report in person to the commanding officer, Fort Assinniboine, Mont., for duty at that station, relieving Assistant Surgeon Paul Shillock. Lieutenant Shillock, upon being relieved, will report in person to the commanding officer, Fort Custer, Mont., for duty at that station, relieving Captain William R. Hall, Assistant Surgeon. Captain Hall, upon being relieved by Lieutenant Shillock, will report in person to the commanding officer, Fort Schuyler, N. Y., for duty at that station, relieving Captain Norton Strong, Assistant Surgeon. Captain Strong, on being relieved by Captain Hall, will report in person to the commanding officer at Fort Meade, South Dakota, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Cronkhite, Henry M., Major and Surgeon, is, by direction of the Secretary of War, relieved from duty at Fort Lewis, Colo., and will report in person to the commanding officer, Fort Trumbull, Conn., for duty at that station, relieving Captain Robert J. Gibson, Assistant Surgeon. Captain Gibson, on being relieved from duty by Major Cronkhite, will report in person to the commanding officer, Fort Sam Houston, Texas, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Appointment.

Vollum, Edward P., Colonel and Surgeon, to be chief medical purveyor with the rank of colonel. August 28, 1890.

Promotions.

Morris, Edward R., Assistant Surgeon, September 17, 1890, to be Assistant Surgeon, U. S. Army, with the rank of Captain, in accordance with the act of June 23, 1874.

Irwin, Bernard J. D., Lieutenant Colonel and Assistant Medical Purveyor, to be surgeon with the rank of colonel. August 28, 1890.

Fryer, Blencowe E., Major and Surgeon, to be assistant medical purveyor with the rank of lieutenant colonel. August 28, 1890.

Cowdrey, Stevens G., Captain and Assistaut Surgeon, to be surgeon with the rank of major. August 28, 1890.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending October 11, 1890:*

Braisted, William C., Detroit, Mich., appointed an assistant surgeon in U. S. Navy.

Wales, P. S., Medical Director. Detached from temporary duty as member of Medical Examining Board.

Ames, H. E., Passed Assistant Surgeon. Detached from temporary duty as member of Medical Examining Board.

Herndon, C. G., Surgeon. Ordered to Naval Hospital, New York.

Persons, R. C., Surgeon. Detached from Naval Hospital, New York, and to wait orders.

Scott, H. B., Passed Assistant Surgeon. Ordered before the Retiring Board.

Price, A. F., Surgeon. Detached from Naval Dispensary, Washington, D. C.

Anderson, Frank, Passed Assistant Surgeon. Ordered to Naval Dispensary, Washington, D. C.

White, C. H., Medical Inspector. Ordered to hold himself in readiness for duty on U. S. Steamer San Francisco.

Braisted, W. C., Assistant Surgeon. Ordered to Army and Naval Hospital, Hot Springs.

Spratling, L. W., Assistant Surgeon. Ordered to hold himself in readiness for orders to the U. S. Steamer San Francisco.

Siegfried, C. A., Surgeon. Ordered to the U. S. Training-ship New Hampshire.

Blackwood, N. P., Assistant Surgeon. Detached from duty in the Bureau of Medicine and Surgery, and granted leave of absence.

Stone, L. H., Assistant Surgeon. Detached from the U. S. Steamer New Hampshire and to wait orders.

Edgar, John M., Passed Assistant Surgeon. Ordered to hold himself in readiness for duty on the U. S. Steamer San Francisco.

Gardner, J. E , Passed Assistant Surgeon. Detached from the Albatross and to wait orders.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service from September 8, 1890, to October 4, 1890:*

Hutton, W. H. H., Surgeon. Detailed as chairman Board of Examiners. October 2, 1890.

Long, W. H., Surgeon. Detailed as member Board of Examiners. October 2. 1890.

Purviance, George, Surgeon. Granted leave of absence for thirty days. September 10, 1890.

Godfrey, John, Surgeon. Detailed as recorder Board of Examiners. October 2, 1890.

Wheeler, W. A., Passed Assistant Surgeon. To proceed to New Orleans, La., for temporary duty. October 3, 1890.

Banks, C. E., Passed Assistant Surgeon. Granted leave of absence for twenty days. October 3, 1890.

Ames, R. P. M., Passed Assistant Surgeon. To proceed to New Orleans, La., for duty. September 13, 1890.

Pettus, W. J., Passed Assistant Surgeon. To proceed to Vineyard Haven, Mass., for temporary duty. October 1, 1890.

Hussey, S. H., Assistant Surgeon. To proceed to New Orleans, La., for temporary duty. September 19, 1890. To proceed to Norfolk, Va., for temporary duty. October 3, 1890.

Wertenbaker, C. P., Assistant Surgeon. Granted leave of absence for twenty days. September 12, 1890.

Perry, J. C., Assistant Surgeon. Upon expiration of leave to rejoin station at Mobile, Ala. September 29, 1890.

Young, G. B., Assistant Surgeon. To proceed to Memphis, Tenn., for temporary duty. September 13, 1890. To rejoin station, St. Louis, Mo., when relieved at Memphis, Tenn. October 3, 1890.

Society Meetings for the Coming Week:

Monday, *October 20th:* New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Conn., City Medical Association; Chicago Medical Society.

Tuesday, *October 21st:* New York Academy of Medicine (Section in Theory and Practice of Medicine); New York Obstetrical Society (private); Medical Societies of the Counties of Kings, St. Lawrence (semi-annual), and Westchester (White Plains), N. Y.; Ogdensburgh, N. Y., Medical Association; Hunterdon, N. J., County Medical Society (Flemington); Baltimore Academy of Medicine.

Wednesday, *October 22d:* New York State Medical Association (first day—New York); New York Surgical Society; New York Pathological Society; American Microscopical Society of the City of New York; Medical Society of the County of Albany, N. Y.; Philadelphia County Medical Society.

Thursday, *October 23d:* New York State Medical Association (second day); New York Academy of Medicine (Section in Obstetrics and Gynæcology); New York Orthopædic Society; Brooklyn Pathological Society; Roxbury, Mass., Society for Medical Improvement (private).

Friday, *October 24th:* New York State Medical Association (third day); Yorkville Medical Association (private); New York Society of German Physicians; New York Clinical Society (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

Letters to the Editor.

THE VIRGINIA STATE MEDICAL SOCIETY.

221 West Twenty-third Street, New York, *October 8, 1890.*

To the Editor of the New York Medical Journal:

Sir: Will you kindly permit me to correct several errors made by your reporter in his abstract of my remarks before the Virginia State Medical Society which are found on page 385 of the Journal? I am no doubt partly responsible for these errors, as I failed to make my meaning plain in *extempore* discourse. In the first place, I did not intend to convey the idea that rheumatism was a frequent sequel of puerperal malarial fever. What I did say was, in an illustrative case of puerperal malarial fever which I narrated, that *acute articular rheumatism* developed subsequently, and that a number of times I had observed this latter disease as a complication of the puerperal state, but *not* frequently. Secondly, in speaking of Mr. Tait's views upon the subject of extra-uterine pregnancy, I insisted that this surgeon had introduced elements of confusion by not distinguishing between retro-uterine hæmatocele properly so called and a free effusion of blood into the peritoneal cavity, and that what he called an *intraperitoneal hæmatocele* was not an *hæmatocele* at all, but simply an escape of blood into the peritoneal cavity. Again. I insisted that the term *extraperitoneal hæmatocele* ought to be discarded, and the name *hæmatoma* used for the escape of blood into the connective tissue of the broad ligaments; and that these distinctions were of the utmost importance in order to understand the relations of tubal pregnancy to *hæmatocele* or *hæmatoma*.

George Tucker Harrison, M. D.

DOBISCH'S LOCAL ANÆSTHETIC.

Home for Habitués, Brooklyn, *October 8, 1890.*

To the Editor of the New York Medical Journal:

Sir: The new local anæsthetic first commended by Dobisch, of Zwittau, has served me so well that I think the Journal readers may be glad to know of it. Its make-up is:

Menthol	1 drachm;
Chloroform	10 drachms;
Ether	15 "

Used as spray.

Though never pushed to complete anæsthesia, it is said to freeze the part in a minute. I have found it very effective in superficial neuralgia, especially about the head; and if, added to its local use, a thin kerchief is placed over the face and the spray thrown on the nose and mouth, enough general effect—yet quite within a safe limit—can be got to add not a little to the local good.

J. B. Mattison, M. D.

Proceedings of Societies.

AMERICAN GYNÆCOLOGICAL SOCIETY.

Fifteenth Annual Meeting, held in Buffalo, September 16, 17, and 18, 1890.

The President, Dr. JOHN P. REYNOLDS, of Boston, in the Chair.

The Diagnosis, Pathology, and Treatment of Extra-uterine Pregnancy.—Dr. A. W. JOHNSTONE, of Danville, Ky., opened a discussion of this subject with an elaborate paper. He stated that the amœboid state was the first picture in the life of all viviparous animals. Immersed in a properly tempered and proportioned nutrient fluid, all alike, from the first segmentation, went on to the formation of the hypoblast, the epiblast, and finally the mesoblast. All after the same plan, with slight modifications, progressed in the formation of their envelopes and temporary organs necessary to intramaternal existence; but, up to a certain point, all that was required of the mother was that she should furnish this properly conditioned fluid. The writer's studies in comparative anatomy had forced him to the conclusion that, in the lower animals, excepting the anthropoids, at no time but when the "rut" was on could this nourishing lymph be furnished, and, without this, pregnancy was out of the question. In the human being and in certain monkeys the "rut" was sempiternal, and, as a matter of fact, the endometrium was ever ready to furnish the necessary nutrient fluid. Pregnancy might, therefore, occur at any time. This nutrient fluid came from the adenoid tissue lining the uterine cavity and the Falloppian tubes. Even the most remote fimbria was possessed of this lining. Strip off the cilia from the epithelium of the tube, and there was left a condition quite analogous to that of the lining of the uterus. These cilia were extremely delicate. He could not believe that ectopic pregnancy could occur unless there was some abnormity in the genital tract. Anything within or without the tube that caused loss of the epithelium, and consequently of the cilia, was sufficient to produce a spot to which the ovum might adhere. Ovarian pregnancy, if there was such a thing, must arise from a peculiar condition. The practical question was, Could ectopic pregnancy be diagnosticated before rupture? The patient did not seek the physician before the occurrence of severe pain, and every colicky pain meant a giving way of some part of the tube. Sometimes the first rupture broke a blood-vessel, but the rule was that hæmorrhage did not occur until the second or third attack. After the discovery of an extra-uterine pregnancy, laparotomy was the only procedure in any sense warrantable. The growth of the gestation sac could not be arrested until the placenta was killed, and the death of the child did not necessarily insure the death of the placenta. Electrical treatment, once so much admired, was wrong in principle, dangerous in practice, and disastrous in its final results.

Dr. MATTHEW D. MANN, of Buffalo, stated that the view that union of the male and female elements of generation must take place in the uterus was erroneous. In ectopic pregnancy the union must occur in or beyond the tube, and most of these pregnancies were primarily tubal. So far as abdominal pregnancies were concerned, the subject was still *sub judice*. There was no rational doubt as to the existence of ovarian gestation. Electricity was of great value ordinarily, for, if the embryo was destroyed, rupture would not occur. After rupture, laparotomy was clearly indicated.

Dr. J. M. BALDY, of Philadelphia, stated that it must be considered that he based his arguments on the supposition that conception had taken place in the tube. He did not wish to place himself on record as denying the possibility of an ovarian or an abdominal gestation, but, whatever the condition might be in the earlier stages, the symptoms were so similar that their distinction was quite out of the question. The following symptoms might be classified as significant or strongly suggestive of ectopic pregnancy: 1. A spurious flow, simulating menstruation, which was at first lighter and afterward darker than the normal menstrual discharge, and which contained clots and shreds. 2. Pain, intermittent and cramp-like, and becoming more severe and more frequent. The situation of this pain was invariably in the pelvis and low in the abdomen, and it might be sufficiently severe to produce syncope. It was usually the symptom that caused the patient to seek her physician, and, in conjunction with the pseudo-menstrual flow, might be accepted as pointing strongly toward the existence of extra-uterine pregnancy. 3. The discharge of shreds of decidua, with or without clots. 4. The general signs of pregnancy. 5. Occasionally the history of a sterility following normal labor or a miscarriage. 6. The vaginal discoloration as in normal pregnancy. 7. The cervix was sometimes appreciably enlarged and the os uteri patulous, but this was not invariably the case. 8. The fundus of the uterus was enlarged and softened and crowded either forward against the pubic bone or to one side. It was more or less immovable and had a feeling of softness. As in the case of the cervix, these conditions were not constant. 9. The uterine appendages sometimes showed a cyst on one side, while an inspection of the other side gave a negative result. The cyst, even if pulsating, was not a positive diagnostic sign. 10. The patient's belief as to whether she was or was not pregnant was quite important in making a diagnosis. 11. In some cases an elevated temperature and an accelerated pulse. 12. At the period of rupture great pain, collapse, and all the signs of internal hæmorrhage. The speaker stated that three propositions were justified by his experience and that of other gynæcologists: 1. In a certain proportion of cases of extra-uterine pregnancy, in the early stages, the diagnosis was easy and unmistakable. 2. In a certain (quite large) proportion of cases sufficient symptoms were present to lead to a diagnosis of extra-uterine pregnancy, although such a pregnancy was not present. 3. In a certain proportion of cases the symptoms, until rupture had occurred, were entirely wanting or of such dubious character as in no wise to warrant a diagnosis of ectopic pregnancy.

A very large number of cases terminated fatally, which rendered expectant treatment somewhat hazardous and made active measures essential. When the diagnosis was reasonably certain, laparotomy was indicated. It was a noticeable fact that many of the physicians who, a year ago, had been among the most ardent admirers of electrical treatment for extra-uterine pregnancy, now seemed to support laparotomy.

A case of tubal gestation with rupture was reported by Dr. CHARLES JEWETT, of Brooklyn, as having occurred in the practice of Dr. F. A. JEWETT.

Dr. A. J. C. SKENE, of Brooklyn, believed that it was highly important that a diagnosis should be made in all cases of extra-uterine pregnancy with equal certainty, whether the treatment contemplated was that by electricity or by laparotomy, in order that patients *in extremis* might be cared for intelligently. He was firmly convinced that extra-uterine pregnancy was as easily diagnosticated as any known affection of the female pelvic organs, if there was no complication of other pelvic disease. In regard to the treatment with electricity, the speaker expressed the regret that it should have been so heatedly and doubtfully discussed, and that it should have received such merciless condemnation from the advocates of laparotomy, and he believed that such acrimonious discussions would never lead to deter-

mining the true value of either method of treatment. He had seen no evidence that electricity was especially dangerous, and believed that it could be employed with entire safety, and its failing to cure did not prejudice in the least the resort to laparotomy. The laparotomists said that their operation must be done by "competent hands." Considering that the cases for laparotomy were emergency cases, perhaps if they examined the histories of the cases that had been operated upon by presumably "competent hands," they would not be so ready to condemn electricity.

Dr. W. W. Jaggard, of Chicago, was sure that the existence of ovarian pregnancy had been proved. A great many cases of so-called tubal pregnancy were simply hæmatoma of the tubes, and many cases of so-called hæmatosalpinx were really tubal pregnancies.

Tubal pregnancy had three terminations: 1. Death before rupture. 2. Rupture. 3. Going on to term. When the tube ruptured, the following subterminations might be observed: 1. Rupture into the broad ligament, with the formation of hæmatoma of the broad ligament. 2. After rupture, the ovum might remain *in situ* and plug up the opening. 3. Rupture with the formation of a retro-uterine hæmatocele. 4. Rupture into the abdomen with intraperitoneal hæmorrhage. With the exception of the last, all these were favorable terminations, and as a rule tubal pregnancy with rupture would end in recovery if left alone. He agreed perfectly with Dr. Skene in regard to the diagnosis being easy in uncomplicated cases. It should be noted that the typical cases of extra-uterine pregnancy occurred in old multiparæ with a long interval between pregnancies, or in primiparæ who had been sterile for a long time. The evidence in favor of laparotomy, where the diagnosis was made before rupture, was conclusive.

There were the following objections to the use of electricity: 1. Danger of rupturing the sac. 2. Uncertainty in diagnosis. 3. After the eighth week it was hopeless to expect resorption of the fœtus or the placenta. He agreed, however, with Dr. Skene that it was well to be temperate in the condemnation of electricity. The proposition that every case of tubal pregnancy with rupture called for laparotomy was erroneous, and had proved most disastrous in practice. The principal indication for laparotomy was free intraperitoneal hæmorrhage. In the event of hæmatoma of the broad ligament or of rupture of the tube, the clot acting as a tampon, the indications were all strongly against laparotomy.

Dr. Howard A. Kelly, of Baltimore, believed it was possible to recognize the following forms of extra-uterine pregnancy: 1. Interstitial. 2. Tubal. 3. Tubo-ovarian (doubtful). 4. Ovarian (proved beyond a doubt). 5. Primary abdominal (remaining to be proved). Tubal gestation might be divided into isthmial, isthmio-ampullar, and ampullar, according to the relative position of the tube. The criterion of ovarian pregnancy was an extra uterine fœtal sac, which must have the same relation to the uterus as the ovary had, the tube remaining intact and the ovarian ligament connecting the side of the sac with the uterus being present. A positive diagnosis of extra-uterine pregnancy could be made if the following symptoms were present: 1. Cessation of menstruation followed by its irregular recurrence. 2. Pain in the lower part of the abdomen. 3. A fluctuating tumor. 4. Enlarged uterus (not always present). 5. A discharge of membrane, which was very characteristic. 6. Milk in the breasts. 7. A tumor diminishing in size under observation, a pathognomonic sign rarely present, unless electricity was used, which of course implied the death of the fœtus. There was a class of doubtful cases where some of the symptoms were present, and there was still another class of uncertain cases where there were no signs, and they were generally discovered accidentally. If he found a freely movable tumor in the abdomen, he would perform laparotomy; but, if the tumor had ruptured into the broad ligament, he would use electricity and wait for results up to the end of the third month. He would not consider the life of the fœtus to the detriment of the life of the mother, but consider the fœtus simply as a malignant foreign body. If there was a living fœtus at term, he would open the abdomen, and if it proved to be an unruptured tube, with the placenta enucleated in the sac, the latter could be removed and the life of the fœtus saved. If the placenta was attached to the intestines, he would remove the fœtus and drop the funis back into the abdominal cavity, and afterward perform laparotomy if necessary.

Dr. Hunter Robb, of Philadelphia, believed that the tubes were the most frequent site of fecundation, but that ovarian pregnancies did take place, and agreed with Dr. Jaggard that microscopical examination was alone reliable in determining this condition. He believed the diagnosis as easy as that of fibroid or parovarian cyst.

Dr. Joseph Taber Johnson, of Washington, remarked that a paper of Dr. Hanks's, read before the society in 1888, had given the histories of eleven cases, with the statement that a diagnosis ought to be possible in ninety or ninety-five per cent. of all cases; that he believed in electricity in the beginning and operation afterward if necessary. He thought electricity would kill the fœtus, and that in all cases of rupture laparotomy should be done at once.

Dr. A. H. Buckmaster, of Brooklyn, thought it would be a fatal blow to the use of electricity in these cases if it should be proved that it could not accomplish the destruction of the fœtus.

Dr. J. A. Temple, of Toronto, related a case of extra-uterine gestation in which he had removed the tumor and tube without rupture. The patient made a good recovery and the stitches were taken out on the sixth day. On the eighth day she had a severe attack of mania; on the twelfth day she became semi-comatose and did not recover consciousness; and on the twenty-third day she died perfectly insensible. He was confident that she did not die from septicæmia or any similar affection as the result of the operation.

Dr. Mann reiterated the views expressed in his paper in regard to the specimen which he presented two years ago, and still held the case to have been one of true ovarian pregnancy. His opinion in regard to the use of electricity in properly elected cases was also unchanged.

Under what Conditions can Electricity be of Positive Service to the Gynæcologist?—A paper on this subject, by Dr. Andrew F. Currier, of New York, was read by title. We are indebted to the author for the following abstract of the paper:

The testimony upon this subject is conflicting. Some have opposed it from prejudice and bias, and others have advocated it with an enthusiasm which revealed indiscretion and unwisdom. Satisfactory knowledge can be gained only by experience, and this necessitates no little expense for the apparatus and time and labor in order to comprehend the physical laws governing electricity. As in religion, art, science, and politics, success only comes as a rule to those who follow up the subject persistently and thoroughly. The patient also must submit to such conditions as will permit of a fair test of the agent. The subject is considered under three headings:

A. Necessary outlay and apparatus.

B. Indications.

C. Contra-indications, cautions, and objections.

The faradaic current is indicated when one desires increased muscular tone or contractile force. Incidentally will

come improved vascularity and nerve energy. The galvanic current is indicated as an astringent, hæmostatic, denutrient, adnutrient, or sedative. For some conditions, for example pain, either current may be effective. All battery currents are based upon Ohm's law that the available battery force equals the entire force generated by all the cells divided by the resistance offered by the wires, the fluid in the cells—in fact, everything which hinders the passage of the current. The unit of usable current in electro therapeutics is the milliampère. The requirements for a faradaic battery are that it be small, simple, clean, and cheap. Gaiffe's costs but a few dollars and is perhaps the best there is. The requirements for a galvanic battery are steadiness of current, cleanliness, simplicity of construction, and durability. The writer has never found a portable battery that answered these requirements, but does not assert that they do not exist. To answer the conditions mentioned there should be a large number of large cells in continuous connection. Either the Law or the Leclanché cells will give satisfaction, the former being more cleanly and more durable. A rheostat and a milliampèremeter are indispensable, and the writer is well pleased with the Bailey rheostat and the Barrett meter graduated to 250. The connecting cords from battery to patient should be long enough for the patient to be moved about without danger of breaking the circuit and giving a shock. For an abdominal electrode Martin's is the best. There are many varieties of vaginal and uterine electrodes, those designed by Apostoli being very good ones. The writer has designed one of aluminium, with a cylindrical removable platinum tip, the shaft being covered with thin rubber tubing. It is light, cheap, and flexible.

The rheostat and meter may rest upon a portable base furnished with suitable binding posts and a switch for changing polarity. The character and effect of the current at the two poles are essentially different. The positive pole will check hæmorrhage and glandular secretion; the negative will not; the positive pole will corrode all but the noble metals; the negative will not. The positive pole is acid; the negative alkaline. At the positive pole oxygen is liberated in the electrolysis of water; at the negative, hydrogen.

The writer's paper contains an analysis of twenty-three cases in which the indications for treatment were: 1. Pain. 2. Hæmorrhage. 3. Inflammatory exudate. 4. Sterility. 5. Dysmenorrhœa. 6. Supersecretion. 7. Hysteria. 8. Uterine subinvolution. 9. Uterine subnutrition.

For pain the positive pole should be within the vagina or uterus, and a weak current is better than a strong one. A good average is 30 milliampères, used from five to eight minutes. The intervals of application should depend upon the duration of the periods in which pain is absent. Pain was relieved in two cases in which it persisted after removal of the uterine annexa, in one each of uterine myoma, pyosalpinx with ovarian apoplexy and endometritis, and two of pelvic peritonitis with exudation. For hæmorrhage the positive pole is believed to be unsurpassed. It was used in a case of interstitial myoma, and in one of malignant disease of the uterus and omentum. Four cases were treated for inflammatory exudate, and in three the exudate was disintegrated and absorbed. But as the diseased organs which had been confined by it became more mobile they also became larger and more sensitive. In five cases sterility was treated with the faradaic current. Impregnation and delivery resulted in two. Dysmenorrhœa may be relieved by either the positive galvanic pole or faradism. Three cases are narrated, but in only one was the result decidedly favorable. For supersecretion the positive pole is preferable to the powerful caustics and escharotics, and yielded good results in three cases. In two cases hysterical symptoms were much modified in addition to benefit which was derived for more palpable lesions.

Subinvolution was successfully treated in one case, the uterus contracting firmly upon the bipolar electrode of Apostoli, and with the faradaic current. Uterine subnutrition in connection with hard anteflexed uteri and usually associated with amenorrhœa, dysmenorrhœa, or sterility will be benefited by the faradaic current. Five patients were treated, and all but one received positive benefit. Under the head of cautions, contra-indications, and objections, nausea resulted in one case, and this observation has frequently been made by others. The passage of the galvanic current may cause faintness, which may be slight or profound, and dizziness. In a case of exophthalmic goître with rapid heart action collapse was imminent on two occasions. An irritable heart, such as is usually present in the last-mentioned disease, and certain chronic gastric disorders, contra-indicate the use of electricity. Maliguant disease within the abdomen is a contra-indication, or at least proved so in one case. Small, dry electrodes should not be applied to the abdomen, but large, wet ones. The former will invariably produce burning. The method of rapid reversals of the galvanic current is of limited usefulness, and should not be used with nervous women. The shocks may be exceedingly harmful. The electro-puncture of fibroid tumors means possible sepsis with its consequences. If it is electricity and not inflammation and sloughing which reduce the nutrition of a tumor, it would seem to be unnecessary. Galvano-cauterization of the uterine mucous membrane seems to furnish the advantages of puncture without the danger. Electro-puncture is also disapproved of for hæmatoma and hæmatocele as dangerous, tedious, and inefficient as to its results. Electricity is the handmaid and not the mistress of surgery, a valuable assistant and increasing in value with experience, but one which demands rational, careful, and intelligent use.

(*To be continued.*)

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Meeting of September 22, 1890.

The President, Dr. A. S. Hunter, in the Chair.

The Initiation Fee.—Dr. C. H. Avery withdrew his motion to reduce the initiation fee from five dollars to one dollar in favor of an amendment to the By-laws recommended by the Comitia Minora to reduce the fee to two dollars. The Comitia also recommended that the editor of the *Medical Directory* be *ex officio* a member of the Comitia Minora.

Nominations.—Nominations were made as follows: For president, Dr. Andrew F. Currier, Dr. O. B. Douglas, Dr. J. L. Corning; for vice-president, Dr. J. L. Corning, Dr. A. M. Jacobus; for secretary, Dr. Charles H. Avery; for assistant secretary, Dr. W. E. Bullard; for treasurer, Dr. John S. Warren; for censors (five to be elected), Dr. George E. Abbott, Dr. William McLaury, Dr. A. S. Hunter, Dr. R. Van Santvoord, Dr. E. A. Maxwell, Dr. G. T. Jackson, Dr. S. O. Vander Poel, Dr. N. G. McMaster, Dr. W. C. Jarvis, Dr. W. Washburne, Dr. C. F. Milne, Dr. G. F. Carey.

The Diagnosis and Treatment of Certain Abdominal Diseases principally characterized by Symptoms of Peritonitis.—Dr. H. T. Hanks based a paper on this subject on experience gained within the past ten years, during which time the treatment of diseases characterized principally by symptoms of peritonitis had undergone considerable change, while much progress had been made in their diagnosis. He thought it wise to interrogate the viscera, one after another, in arriving at a diagnosis in not perfectly clear cases. Conjoined manipulation *per rectum*

et vaginam was often necessary, and might be aided by a few whiffs of an anæsthetic. Experience had taught us that many cases which formerly would have been regarded as primary peritonitis could now be made out as secondary. He believed that only three cases of idiopathic peritonitis had ever come under his own observation, and in those the diagnosis had not been confirmed by an autopsy. The symptoms which formerly would have been regarded as diagnostic of peritonitis—pain in the abdomen, tympanites, rapid pulse, pinched face, etc.—it was now known might be due to perihepatitis, metritis, gastritis, acute congestion of the kidneys, etc., and the important question arose whether the former treatment of peritonitis (by opium) would cure such cases. Evidently it would not in many instances. How, for instance, could it be expected that large doses of opium would cure twisting of an ovarian pedicle, of which condition the chief symptoms might be those of peritonitis?

Where the surgical indications had not become clear, the author would treat a case characterized by symptoms of peritonitis with saline cathartics, sufficient codeine to give comfort (opium was objected to as being constipating in its effects), the ice coil where fever was high, and leeches; perhaps enemata might have to take the place of salines. The case should be constantly watched, since the abdominal surgeon might have to be called at any time. These remarks applied in a general way to appendicitis as well as to other conditions, and he could say that if the case was seen early an appendicitis could thus be made to undergo resolution; if, however, an abscess formed, an operation should be resorted to, although the mortality in operative cases had been very large.

Dr. A. Jacobi discussed the subject as applied to children, and said that peritonitis in the infant was about the same anatomically and pathologically, and largely ætiologically, as in the adult. He thought a large number of cases were mistaken for peritonitis which were of some other nature, while a still larger number were in reality peritonitis mistaken for some other condition. This had been shown in a paper he had once read before the Virginia State Medical Society. Many cases of so called stomach-ache in infants and adults were new or recurrent attacks of peritonitis. Agglutinations between the intestines were often found at autopsy which had not been suspected during life; they meant peritonitis. Old typhoid ulcers sometimes perforated and caused peritonitis. In many instances repeated belly-ache in children was due to perityphlitis. In chronic peritonitis, with acute or subacute attacks, the bowels should be supported by a snug bandage covering the whole abdomen. Regarding the old treatment by opium and the modern by purgation, there seemed a wide difference, which might perhaps be accounted for by different classes of cases. And where laxatives proved beneficial, was not a narcotic for rest demanded subsequently? He gave a laxative, followed it by opium, but admitted that he was sometimes unable to tell whether the stage had yet passed for a saline, and opium was demanded.

Dr. W. H. Thomson spoke of purulent peritonitis at the terminal stage of Bright's disease, which was so often overlooked until the body reached the post-mortem room. Among its indications was a rapid, small, incompressible pulse, with little or no elevation of the temperature. The incompressibility of the pulse was different from that pertaining to the kidney disease itself. He also mentioned the fact that in perforation during typhoid fever there was frequently no rise, perhaps a fall, of the temperature, which was due to sudden shock. The surgeon alone could here give relief. The pain in cirrhosis of the liver, common in alcoholics, was oftener due to peritonitis than to gastritis or gastro-duodenitis. He further said in connection with diagnosis that sudden pain followed by symptoms of general peritonitis was very different from steadily increasing pain, and pointed to perforation of a hollow viscus.

Dr. C. C. Lee said his remarks would be based chiefly on surgical experience. There were three classes of cases: 1. Those of septic nature, in which the cause of sepsis should be removed. When peritonitis of this nature developed after an abdominal operation there was likely to be remarkable absence of severe pain, due, he supposed, to the obtunding of the nerve centers by septic matter covering a large surface, the symptoms simulating malarial conditions. Many such cases were now saved by re-opening the abdomen while formerly they died. 2. What might be called acute traumatic peritonitis. In this class of cases abdominal surgeons were responsible for what he thought was a heresy in announcing that salines would be likely to result uniformly successfully. He had treated cases in that way vigorously, and had yet to see one do well in which the treatment was kept up, except there were obstruction by gas or fæcal accumulation. Now he began with a saline cathartic, then gave opium to quiet the bowels. He admitted the arguments in favor of codeine. The ice coil was useful only during the formative stage, and was contra-indicated after plastic deposit. 3. Secondary peritonitis. Here success required removal of the cause. He thought we would reach the period when there would be less abdominal surgery than to-day.

Dr. E. H. Grandin spoke of puerperal cases, and said that during his early professional career he at once began dosing the patient with opium, and she died. Now, when he saw his patients early they got well, and his treatment consisted in the use of salines and the avoidance of opium as far as possible. The vagina and uterus should be clean; if a pyosalpinx or ovarian abscess had ruptured, the surgeon would have to act.

Dr. Ralph Waldo had seen patients who had been treated successfully for an attack or repeated attacks of peritonitis by opiates, but, they being hyperæsthetic, the physician was led to continue the narcotic too long, and complications developed, such as fæcal impaction and digestive derangement. This occurred so frequently that it seemed necessary to say a word of caution.

Dr. R. A. Murray thought primary peritonitis occurred but seldom. Further, that severe attacks were infrequently recovered from, whatever the treatment. Probably most of us saw more of puerperal peritonitis than of any other kind, and treatment by either opium or laxatives failed simply for the reason that the cause was not removed—that is, sepsis. Where peritonitis was ushered in after laparotomy, by giving a saline one certainly took away the serum which furnished a nidus for germs; he should then quiet the bowels and enhance digestion by small doses of opium; or, if there was shock, give large doses, for opium was a powerful heart stimulant.

NEW YORK ACADEMY OF MEDICINE.

Meeting of October 2, 1890.

The President, Dr. Alfred L. Loomis, in the Chair.

The New Building.—The President, on calling the meeting to order, explained that, while the effort to have the new building ready for the opening work of the session had been successful, the formal inauguration would not take place until the second meeting in November, on the date fixed for the anniversary oration.

Skin Grafting after the Method of Thiersch. — Dr. Charles McBurney read a paper on this subject. After describing Reverdin's well-known method, the author went fully into the details of skin grafting as practiced by Thiersch and as modified by himself. According to Thiersch, all strong anti-

septics were to be avoided in skin grafting, as the effect of these upon the cellular elements, upon the capillaries, and upon the blood itself was such as to seriously endanger and even prevent the immediate union between the grafts and the surfaces upon which they were placed. Thiersch himself used absolutely no solution except one of common salt in water, in the proportion of six parts to one thousand. The speaker was convinced of the importance of sterilizing this solution. It was his practice to use distilled water, boiling the solution before using it, and also to employ a solution of bichloride of mercury freely in disinfecting the ulcerated surface, as well as the surface from which the grafts were to be taken, completely washing away all of this solution with the saline one of Thiersch just before operating. The parts should be thoroughly washed with soap and water, and all hair should be removed by careful shaving. In some cases grafts might be placed with success directly upon the unbroken surface of healthy granulations, but a much more certain method of insuring success, and, according to Thiersch, one essential to the avoidance of subsequent contraction, was to remove, by curetting, the superficial layer of granulations, and also the tough cicatricial edge of the ulcer. A bleeding surface was thus produced on which many open capillaries existed, and which was very favorable to immediate union of the grafts. The author had found it more rapid and convenient to use the knife. With a sharp scalpel an incision nearly or quite through the true skin was rapidly made entirely around the ulcer just outside its thickened border. With the same instrument the whole area included by the incision was shaved off. A smooth, bleeding, healthy surface was thus produced. This surface was immediately irrigated with the sterilized salt solution and compresses of sterilized gauze were placed upon it to control bleeding.

The question of hæmorrhage at this stage of the operation was one of considerable importance. If grafts were placed while bleeding still went on, the risk of failure was much increased. Accumulations of blood, even small ones, beneath the grafts frequently induced their necrosis, and saturation of the dressings with blood was favorable to infection. But all ulcerations, and particularly those on the lower extremities, when shaved, were liable to bleed actively for a long time. The use of Esmarch's constricting band was found to entirely dispose of the question of hæmorrhage, to shorten the whole operation greatly, and not in the least to affect the vitality of the grafts. When, therefore, the situation of the ulcer was such that the band could be applied, it was put on above the whole field of operation, thus rendering the process a nearly bloodless one. The grafts might then be immediately applied and the dressings put on. The grafts themselves illustrated most decidedly the originality of the Thiersch method. They consisted of thin slices of skin, removed by shaving parallel with the surface. The author had found a broad razor with a very delicate edge the best instrument for this purpose. The most convenient points from which to take the grafts were the front and outer part of the thigh and the outer surface of the upper arm. Taking the razor, the operator wet it in the salt solution, and, applying the edge at the most distant part of the stretched skin, with a rapid sawing motion toward himself shaved off as thin, long, and wide a shaving as he could. Four or five inches in length and an inch in width were about the dimensions of a first-rate graft. The grafts might or could be of a variety of thicknesses, but no graft would do well that was thick enough to include fat upon its lower surface. As it was being cut the graft piled up on the razor. After it was separated from the skin, a few drops of the salt solution should be dropped on it, and the razor be immediately carried to the edge of the surface to be covered. With a probe, one end of the graft was then teased off the razor to the raw surface, and while it was held there the razor could be slipped from under it across the surface so as to unfold the graft and deposit it in place. The graft could then be readily adjusted with two probes. It should be so placed that its edge would follow up the perpendicular edge of the prepared surface and reach very slightly on to the uncut skin. In that manner graft after graft was placed, great care being taken that the edges were in neat apposition to one another, and were at no point folded under. From time to time a little salt solution should be sprinkled on the grafts already placed to prevent their becoming too dry, which would destroy their vitality. Strips of Lister protective or of thin rubber tissue, about an inch wide and long enough to a little more than cross the grafted surface, should then be laid on like shingles, overlapping one another over the entire area. These strips, previously sterilized in bichloride or carbolic-acid solution, just before using should be drawn through the salt solution. They should be gently pressed on the grafts, and then covered with some soft sterilized material, such as a compress. This substance should be wet in the salt solution and piled up over the protective; over this again a large piece of protective or rubber tissue should be applied to prevent rapid evaporation, and finally a well-applied gauze bandage. The surface from which the grafts were taken did well under the salt solution. After wetting the surface, the part was completely covered with rubber tissue and dressed with sterilized gauze. This method of dealing with the denuded surface had given entire satisfaction.

The variety of lesions to which Thiersch's method was adapted was very large. It included all ulcerations upon any part of the external surface. Those not familiar with the method would be surprised to see how perfectly and successfully these grafts could be applied to the surfaces produced by extensive operations for the removal of malignant and other tumors—to any raw surface, in fact, which could not be covered by the adjacent skin. It was astonishing to see the variety of tissue to which the grafts would adhere firmly. Muscle, fascia, cartilage, and even bone might all be successfully grafted. The most favorable surface was a clean muscular one, and the least, the surface of compact bone.

In one case, after the removal of an extensive carcinoma of the face, a large area of lower jaw was completely bared. Grafts laid over this surface had adhered almost perfectly throughout, and at the end of a week those that covered the bone were found to be soundly attached to it. In another case a surface several inches in diameter on the back of the forearm included a number of extensor tendons. The grafts applied were more than usually successful, and complete healing was rapidly attained. The breast cases were of special interest, as entire liberty could be taken in thorough removal of the disease, for the denuded surface could be covered without resorting to any plastic operation. Thiersch advised that the gauze placed immediately over the protective should be kept constantly moist with salt solution, and said that to effect this it was necessary to moisten the gauze every four hours. As this was very laborious, the author had extended the time to once in two days, and the cases treated in this manner had done very well. At the end of forty-eight hours the dressings were all removed except the protective, which lay next to the grafts. A fresh wet dressing was applied and changed again after two days. By that time there was usually some formation of pus, as it was unusual for a case to go on a whole week without some suppuration. It should be carefully removed and fresh dressing applied. It was the author's practice to leave the protective in place from ten to fourteen days, as the too early application of a dry dressing destroyed the vitality of the grafts. The author then reported twenty-five cases which represented

a considerable variety, as regarded both the size and the character of the surface grafted. The length of time occupied in attaining sound healing had varied from a week to two months. In regard to the permanency of the grafts, his experience showed it to be remarkably good. While there was no contention made that Thiersch's grafting would prevent the return of malignant disease, it was certainly much to be desired that after all operations for malignant disease the wounds should be healed at the earliest possible moment, and the application of the method would not fail to convince one of its great value. A number of patients were then presented for inspection.

Dr. L. A. Stimson's experience with the method was, he said, comparatively limited. He admitted having always felt a certain want of confidence in it until he had learned of Dr. McBurney's recent successes. Since then he had employed it and had got some good results. His general experience with the employment of the method for the treatment of ulcers was that, while healing was often prompt, there existed a tendency to return of the trouble. He believed, however, that in cases in which large areas of surface were of necessity exposed, with great loss of substance, the method was destined to take the place of plastic operations. In inoperable cases of malignant disease in which much destruction of substance existed he had essayed the use of grafts upon the freshened surfaces, but so far without success. He thought if later experience showed that this could be satisfactorily done it would be a most desirable application of the method.

Dr. H. Knapp explained that he had witnessed grafting in Thiersch's clinic. In his own practice it was successful enough in operation upon the upper eyelid, but not so much so on the lower. The drawback was the enormous shrinkage which followed. It was his custom to adopt Wolfe's method.

Dr. P. A. Morrow said that he had used much thicker grafts than the mere superficial layer of skin. He had taken grafts that included the entire derma and subcutaneous tissue. He had recently thus repaired a scar of long standing upon a patient's scalp. He had used a small punch or trephine and had taken buttons of material from the opposite side and transplanted them into incisions in the scar tissue, fitting them with mathematical accuracy. Perfect union had resulted within a week. No dressings were used except gutta-percha over the site of the operation. Then he had taken portions of scalp a quarter of an inch thick from another individual. These also had united within a week, no suppuration ensuing. The new grafts had all continued to bear hairs luxuriously. It was usually difficult to obtain such material. He did not think that any tissue had ever been previously grafted to produce growth of hair. Such grafts had hitherto not been taken deep enough to include the essential elements of hair growth. In the experiments he had thus made there had been no indication of the breaking down of tissue. He thought the method he had described would have a range of applicability in such cases as circumscribed lupus, moles, warty growths, and so on. In the case he had described it had been almost impossible to discover the line of demarkation after healing. Of course he had not neglected the use of antiseptic precautions, such as the use of bichloride and carbolic acid.

Dr. Bulkley objected to Thiersch's method on the ground that the skin which covered the ulcer was of such thinness as to break down readily. He also thought that if the whole thickness of the skin was used a better result would be obtained. Reverdin's method had proved very satisfactory in his practice.

Dr. McBurney said that all the methods that had been mentioned had their special applications. The transplantation of buttons of skin seemed a very valuable plan, but of course such grafts could not be used over surfaces eight or ten inches in diameter or on ulcerated areas. He thought no method could equal Thiersch's in applicability to a wide range of requirements.

MEDICO-CHIRURGICAL SOCIETY OF MONTREAL.

Meeting of October 3, 1890.

The President, Dr. George Armstrong, in the Chair.

A Case of Hodgkin's Disease.—Dr. R. L. MacDonnell exhibited a young man, aged twenty-five, a freight-checker, who was the subject of Hodgkin's disease. Up to four years ago the patient had enjoyed good health, but at about that time he began to suffer from a severe and prolonged attack of what was called bronchitis. There were severe attacks of dyspnœa, which came on on exertion and when he was at rest, and cough was very severe and brassy. He made a good recovery and continued well until two years ago, when he began to notice the presence of lumps in his neck. These gradually increased in size and number. Two months ago the breathing became seriously embarrassed, and suffocative attacks of the severest kind occurred, especially when he was in the recumbent posture. In the beginning of August he presented himself at the Montreal General Hospital suffering from attacks of dyspnœa and from a brassy cough. On August 11th a chain of glands was removed from the front of the trachea. These were found to extend very deep into the chest and were thought to be continuous with other enlarged glands in the mediastinum. He made a good recovery from the operation, and since then he had not suffered from any attacks of dyspnœa, though his breath was short on exertion and he still suffered from cough. He remembered that frequently when he was a boy there were large lumps in the arm-pit. Epistaxis had been frequent during the last six months. There was no history of any venereal disease. The glands in the left side of the neck were all enlarged, especially those situated behind the sterno-mastoid. They were prominent, distinct from each other, loosely attached, and of firm structure. There were two or three enlarged glands in each axilla, but none in the groin. The spleen was somewhat enlarged, but was not palpable below the ribs. The liver was of normal size. Examination of the urine yielded a negative result. The skin generally was clammy, but always on the left side of the forehead and face there was very free perspiration. The left pupil was much larger than the right. Physical examination of the heart and lungs revealed nothing. The temperature in the afternoon had generally been 1° or 1·5° above normal. The pulse was always between 100 and 110. No member of the family had ever suffered from enlarged glands. There was a large excess of white cells in the blood. For the last month Fowler's solution had been taken regularly, with an apparently good result. About a fortnight ago the patient had a severe syncopal attack.

After the members of the society had fully examined the patient Dr. MacDonnell stated that the diagnosis was no matter of doubt. The history of indolent enlargement of the glands extending along the course of the great vessels following the route described by Hodgkin, involving first the cervical and then traveling downward, together with the altered composition of the blood and the enlargement of the spleen, combined to complete the clinical picture. But the most interesting point in the case was the interference with the cervical sympathetic, as was shown by the dilated pupil, the unilateral sweating of the face, and the accelerated pulse. Interference with cardiac innervation probably accounted for the attacks of syncope.

Dr. H. S. Birkett had had the patient under his care previously to his admission into the Montreal General Hospital. He had examined him for the first time on the 6th of June last, when he complained of hoarseness, which had been present for

the preceding two weeks. There was also considerable dyspnœa. Laryngoscopic examination proved the presence of small superficial ulcers situated one on the middle third of each vocal cord and directly opposed to each other. The base of each ulcer was pale and the surrounding tissue slightly hyperæmic. The pharynx was decidedly anæmic. The lymphatic glands in the neck were found to be enlarged, especially those about the sterno-mastoid, and so were the three lobes of the thyreoid. Thinking that this was a case of tuberculosis with laryngeal manifestations, Dr. Birkett had examined the lungs, but a careful examination failed to reveal any lesion. The temperature was slightly elevated (100°) and the pulse 96. This, in conjunction with the foregoing laryngeal condition, had led him to regard the case as one of localized tuberculosis, due probably to a caseating degeneration going on in the enlarged glands in the neck; but, in order to have more satisfactory proof, the sputum was examined by Dr. Wyatt Johnston, who reported absence of both tubercle bacillus and elastic tissue. The laryngeal condition was then regarded as one of chronic inflammation in which superficial ulceration had taken place. Before the report of the sputum was received the case was treated as one of tuberculosis, and lactic acid of varying strength was used. The ulcers having healed rapidly, Dr. Birkett had thought he had cured a case of tuberculosis of the larynx, but the result of the examination of the sputum put this idea to one side. About the 1st of August the dyspnœa began to increase, and laryngoscopic examination showed that there was pressure on the anterior wall of the trachea, due undoubtedly to an enlarged gland situated on the middle lobe of the thyreoid. As the dyspnœa continued to increase, surgical interference was advised.

Dr. Wesley Mills thought the case was one that seemed to teach some physiology, or at all events to illustrate some of the latest conclusions of that science. Was the disease of the glands, together with the symptoms referable to the iris and sweat glands, consequent on a disease of the nervous system expressing itself through the sympathetic nerves, or did they all arise from pressure or irritation of the sympathetic by the enlarged glands? Believing as he did that the whole function of nutrition was under the influence and direction of the nervous system, he would not exclude the lymphatic glands and other blood-forming organs. In this instance, however, it was possible to explain the dilatation, the localized sweating, and the rapid action of the heart by irritation of the sympathetic. The first and second could be imitated experimentally, and it had lately been shown by himself and others that the accelerator nerves of the heart had a definite course in most animals. They were given off either from the first thoracic or from the two lower cervical ganglia. Accelerator fibers ran in the vagus also. Possibly the syncope that had occurred had been due to cardiac exhaustion from overaction of the sympathetic, rather than to cardiac inhibition proper. It was likely that the most important of the accelerator branches in man were given off from the middle cervical ganglion.

Dr. Shepherd drew attention to the shape of the patient's neck, which he thought was peculiar to Hodgkin's disease, and described briefly the operation of removing the glands from the front of the trachea, which he had found a very difficult undertaking. The chain of glands had extended so deep that at the bottom of the incision the transverse arch of the aorta could be felt.

Fragilitas Ossium.—Dr. Roddick exhibited a boy of thirteen who had been the subject of twenty-seven fractures of the lower extremity. The first fracture was of the right thigh and occurred when the boy was a year old. Union took place after each fracture with abundant new growth of bone, but the more recent fractures refused to unite readily, and at present a false joint existed in the middle of the left femur. The fractures were produced by very slight violence and in most instances were quite painless. The cause of this condition could not be ascertained. The family history was very good. The brothers and sisters of the patient were in excellent health. Dr. Roddick proposed amputation, as both legs were utterly useless and atrophied to an extreme degree.

Exhibition of Patients on whom Osteotomy had been performed.—Dr. James Bell showed two children on whom, he had operated for the relief of genu valgum and for the opposite condition of bow-legs. The result had been excellent. In both patients the legs had been perfectly straightened. Their histories he related as follows:

Case I.—A healthy, strong boy, five years and a half old, was one of a family of several children all of whom had suffered from rickets and subsequent bony deformities, which, however, had all been fairly well outgrown and had not required operative or other treatment. The patient had suffered from rickets when two years and a half of age, and, on admission into the hospital (nearly three years later), presented marked deformity of all the long bones, the most conspicuous deformity being a very pronounced condition of genu valgum, so that the knees completely overlapped in walking. On the 5th of May, 1890, this deformity was corrected by a double osteotomy by Macewen's method. On section, the bones were found to be exceedingly hard and brittle. No bad symptoms followed, and the boy now walked without any apparent deformity.

Case II.—A boy, aged three years and a half, was brought to the hospital with very marked bow-legs. All the long bones were deformed, but the tibiæ and fibulæ most of all. There was great anterior convexity of the lower third of the tibiæ. Double linear osteotomy with section of both Achilles tendons was done on the 1st of June. On section, the bones were very soft and the deformities easily corrected. No bad symptoms followed and the child now walked perfectly and without evident deformity. This child had been well and strong and had straight, well-formed limbs until she was eighteen months old, when she became ill. The history was a typical one of rickets. She became unable to walk for a time, and when she was recovering, the bony deformities occurred.

Pathological Specimens.—Dr. Wyatt Johnston exhibited a myoma of the uterus and a myosarcoma of the uterus. These specimens were exhibited for Dr. Gardner. The first had been removed from a patient, twenty-five years of age, whom he had had under observation several years before, and for whom he had advised removal of the uterine appendages. The tumor was very large and very closely adherent to the structures, from which it was extremely difficult to separate it without causing severe hæmorrhage. In the second case the age of the patient was forty-two. The tumor had been of rapid growth, and was removed without any difficulty. The third specimen was a fibro-cystic tumor of the ovary. In this case the tumor was found to be freely movable, hard, and painful. The pelvis was filled with an immovable mass. Abdominal section was performed by Dr. Shepherd, who found the tumor covered by intestines and intimately adherent to the adjacent structures. The recovery of the patient had been uninterrupted. The fourth specimen was one of tuberculosis of the heart. It was from the body of a child that had died of general tuberculosis. The heart had become attacked, as was shown by a small tubercular nodule in one of the aortic valves.

Sudden Death in the Course of Mild Typhoid Fever.—Dr. McGannon, of Brockville, related the history of a girl, fourteen years of age, in whose family there were other cases of fever, but who, up to within a few days of her death, had been engaged in housework, though she felt ill. She was feverish

when seen by Dr. McGannon, but no serious symptoms were present. Sudden death occurred by syncope. There was no autopsy.

New Inventions, etc.

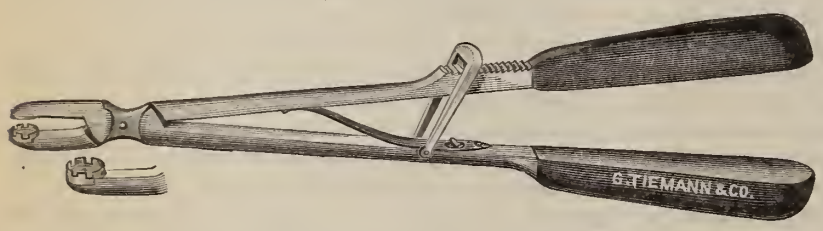
THE UNIVERSAL NEEDLE FORCEPS.

By O. G. Pfaff, M. D.,
CLINICAL LECTURER ON DISEASES OF WOMEN, MEDICAL COLLEGE OF INDIANA.

The Hagadorn is without doubt the most popular needle ever invented, and it has been also heretofore the most difficult to manipulate. The very few forceps which can be used at all with these needles almost without exception compel the operator to hold the needle at an exact right angle with his instrument. It is maintained by some that nothing more is required. In most instances this is true, but the demands of the exceptional cases are imperative, and the comfort of the operator promotes the patient's welfare.

The ideal needle forceps should hold any kind of needle whatever, of any shape or size, in any position which the operator may find most convenient.

I have devised such an instrument, which is made by Tiemann & Co., of New York. It fulfills all the indications. By means of it I have been enabled to dispense with the Peaslee needle in laparotomy,



and thus to simplify this operation by a gain of some little time. I hold the properly curved Hagadorn needle directly in the end of and parallel to the forceps, introducing it like a Peaslee needle, carrying it on through both walls and out, completing each suture in one motion, as in other operations.

The accompanying cut renders a detailed description of the instrument unnecessary. The disc for receiving the needle is the distinctive feature of the instrument. It is a small "turn-table," with an excavated surface to accommodate curved needles, and square-cut grooves in which rests the needle when grasped for action. This "turn-table" occupies the extreme point of the lower jaw, while a copper plate fits it neatly from above. The handles are of vulcanized rubber, baked into the metal, and every part of the instrument can be easily removed for cleaning, thus meeting the demands of antiseptic surgery.

Miscellany.

Certain Causes of Major Pelvic Troubles, traceable to Minor Gynæcology.—At a recent meeting of the Philadelphia County Medical Society Dr. Joseph Price read the following paper:

With the present popular cry of "conservatism," in reference to operation in cases where it is held that all treatment should be tried previous to real surgical interference, it is worth while asking whether this preliminary treatment should not itself be abandoned in the hands of those who plead most pathetically for it. Their cry is not a scientific plea, but in most instances a *personal bid* for indulgence while they try to accomplish something, without acknowledging on the one hand that there is little or nothing to encourage them in their work, so far as results are concerned; and on the other, that there are abundant proofs from the cases that have come out from under their hands, with one treatment or another, that manifold really major surgical affections arise merely from treatment recognized as orthodox from the standpoint of minor gynæcology. So far as my own experience is concerned, I do not hesitate to put minor gynæcology in a causal relation with a vast amount of the necessary major pelvic surgery coming under my attention.

First among these causes may be mentioned the Emmet cervical operation. Like many other surgical operations, this, when first explained by its distinguished originator, was done in season and out, by every one, without the least consideration of its contra-indications. Very many minor tears of the cervix, in which a cosmetic effect only is obtained by operation, are made distinctly worse by operative interference. In many cases the pain becomes insufferable, from the lighting up of a dormant or unrecognized pelvic trouble, and operation is required to undo the mischief of an unnecessary cervical closure. This fact has been recognized by Emmet himself, and he has counseled the careful selection of cases in order to escape these disastrous results. It should be set down that where there is pre-existing pelvic disease, even though slight, no cervical operation ought to be tried unless absolutely required by the condition of the patient. Another operation which has met with much approval in many directions, and which some measure of success seems to follow in some cases, is the forcible dilatation of the cervix. It is clear that where there is antecedent inflammation of the pelvic viscera—that is, of the genito-urinary system—such an operation as surgical dilatation of the cervix can not be free from danger. In order to relieve dysmenorrhœa by this procedure, it must evidently be due to stenosis of the os or cervix. The question here arises, Can it be told, in dysmenorrhœa, wherein its causes lie? Sometimes, but not infallibly. The fact is, that in many women where a stenosis would be diagnosticated, there is no difficulty whatever attending the menstrual flux. This being the case, it is evident that a diagnosis can not be made by simple observation without a careful study of all the symptoms. Again, in many women the causes for this condition are complex. It will not do to lose sight of this, and conclude that because a flexion exists, dilatation will remedy menstrual pain. It is to be remembered that if there is co-existing pelvic inflammation, dilatation will increase it, and, under certain conditions, cause it if absent. Rapid dilatation of the cervix is a distinct traumatism, and along with it run all the dangers incident to septic absorption that attend any other violent procedure, and where traumatism incident to natural causes is confessed to be the cause of so much subsequent mischief, it ought not to be *expected that operative injury can be harmless.* This conclusion, reached inferentially, has been abundantly confirmed practically on the operative table by much of my later pelvic work. In a number of cases with a history of preceding dilatation the after-operation has exhibited an inflammatory condition of affairs as complicated as any other in my experience. Some of the dilatations were done with pre-existing disease, which was made worse by this interference, while others were done simply to relieve the dysmenorrhœa, and resulted in the establishment of a complicated surgical disease in which operation was *necessary purely to save life.* All in all, I believe that, judged simply by its remoter effects, the operation of rapid dilatation is a dangerous one, *and results oftener in subsequent harm than in lasting good.* The surgical injury to the cervix is, in many of these cases, more pronounced than the tears of the cervix which it is the intention to remedy by Emmet's operation. In this case there is operation at each horn of the dilemma, and the results are often equally bad at both. Simple closure of the cervix in cases of pelvic disorder almost certainly exacerbates the symptoms. The necessary inflammatory action set up in the suture tract is transferred along the lymphatic or venous channels to the seat of the earlier inflammation; this is lighted up anew, and goes on in its development until a pelvic peritonitis is kindled or rekindled, which at last entails a major operation. The minor gynæcologist, as such, who has no regard for or appreciation of the relation of the commonly advocated general closure of perineal and cervical tears to major surgical complications, can not but be a great factor in the causation of the same. In Pepper's *System of*

Medicine, vol. iv, there is on record a case in which the operator hoped to cure a pelvic inflammation by the derivative effect of a perineal or cervical operation. Needless to say, pelvic operation was afterward done. Such a cure is no less ridiculous than the so-called "faith" cure, and is certainly more *actively* harmful.

That the inconsiderate use of the uterine sound has been responsible for much inflammatory pelvic trouble is scarcely to be disputed. This is not because the sound is of itself a dangerous instrument, but because it is put into the hands of every tyro as an instrument of diagnosis. If used at all, it should be in the hands of those with whom its application, by reason of their skill, will be exceptional, not usual, and the rule should be that in the hands of a non-expert it should be forbidden. The more expert and experienced the specialist, the more rarely will the instrument be required. My own rule is that, in cases in which it might at first seem indicated, a little patience and diligence will obviate the necessity of employing it. The indiscriminate use of the sound and electrode is the most serious mechanical objection to the employment of electricity. Every sitting for the electrical treatment is prefaced by the use of the sound, and followed necessarily by the introduction of an electrode of some form. This is by a class of men who, in the main, have had no *previous gynæcological training or education whatever*. In such hands such methods can only be harmful, and we are now reaping the fruits of their work in a class of pelvic operations not surpassed in the complications presented. Along with the sound may be placed the curette in the same category. Dilatation and curetting of the uterus have placed to their credit a long *series of major operations*.

Another class of cases coming under this head are those in which there has been a long time during which intra-uterine applications have been made. All the caustics in the catalogue have at one time or another been in favor as cure-alls in intra-uterine therapeutics—nitric acid, chromic acid, nitrate of silver, and the rest. For a woman to have undergone a routine treatment with this list, and to have escaped pelvic inflammatory trouble, is little short of a miracle. A careful inquiry into many of the cases coming under my care directly and indirectly reveals the history that all sorts of minor procedures were tried, only to fail and apparently hasten the necessity for operation. I shall refer to and illustrate these points by the citation of cases in the discussion.

The New York State Medical Association will hold its seventh annual meeting in the Mott Memorial Hall, No. 64 Madison Avenue, New York, on Wednesday, Thursday, and Friday, the 22d, 23d, and 24th inst., under the presidency of Dr. John G. Orton, of New York. The programme includes the following items: An address in medicine. Prognostics in Medicine, by Dr. John Cronyn, of Erie Co.; The Mimicry of Animal Tuberculosis in Vegetable Forms, by Dr. E. F. Brush, of Westchester Co.; A New Method of Surgical Treatment in Certain Forms of Retro-displacements of the Uterus with Adhesions, by Dr. A. Palmer Dudley, of New York Co.; a discussion on intracranial lesions (to be opened by Dr. W. W. Keen, of Pennsylvania, with a paper on The Diagnosis and Treatment of Intracranial Lesions, propounding questions under the following divisions: I. Localization [cerebral topography]; II. Nature of the lesions; III. Indications for operative treatment; IV. Technique of operation; V. Results. Question 1. What are the present means of localizing intracranial lesions? Question 2. What is the nature of the chief intracranial lesions (hæmorrhage, abscesses, tumors), and how can they be discriminated? Question 3. What are the indications and contra-indications of operative interference in cases of intracranial lesions? Question 4. What are the best modes of operating in cases of intracranial lesions? Question 5. What are the immediate and also the remote results of operative treatment in cases of incracranial lesions? These questions will be discussed by Dr. James J. Putnam, of Massachusetts; Dr. Charles K. Mills, of Pennsylvania; Dr. Donald Maclean, of Michigan; Dr. John B. Roberts, of Pennsylvania; Dr. Charles McBurney, of New York Co.; Dr. Frederic S. Dennis, of New York Co.; Dr. Stephen Smith, of New York Co.; Dr. John A. Wyeth, of New York Co.; Dr. Joseph D. Bryant, of New York Co.; and Dr. Thomas H. Manley, of New York Co.); Hypnotism, by Dr. H. Ernest Schmidt, of Westchester Co.; Retention of Urine from Prostatic Obstruction—its Nature, Diagnosis, and Management, by Dr. John W. S. Gouley, of New York Co.; The Specific Treatment of Typhoid Fever, by Dr. Gustavus Eliot, of Connecticut; an address in surgery, The Ligature of Arteries, by Dr. Stephen Smith, of New York Co.; The Death Penalty. Does the Garrote or Hanging ever produce Instantaneous Unconsciousness? by Dr. George E. Fell, of Erie Co.; The Therapeutics of Exophthalmic Goitre, by Dr. E. D. Ferguson, of Rensselaer Co.; The Technique of Laparo-hysterectomy, with Illustrative Cases, by Dr. Ely Van de Warker, of Onondaga Co.; a discussion on obstetrics (to be opened by Dr. S. B. Wylie McLeod, of New York County, with a paper propounding the following questions: Question 1. How may the present prophylactic measures in obstetrics be more extended and applied? Question 2. Is the present technique in the management of labor and convalescence in accordance with sound physiology? Question 3. To what extent have the surgical means of treatment of labor complications been successful, or should these complications and the process of repair have been more generally left to nature? Question 4. What influence would a more advanced obstetric science have on the biological and social condition of the race? These questions will be discussed by Dr. Ira B. Read, of New York Co.; Dr. Henry D. Nicoll, of New York Co.; Dr. William McCollom, of Kings Co.; Dr. Joseph W. Stickler, of New Jersey; Dr. George T. Harrison, of New York Co.; Dr. Timothy J. McGillicuddy, of New York Co.; Dr. Palmer Dudley, of New York Co.; Dr. William H. Robb, of Montgomery Co.; and Dr. Alfred L. Carroll, of New York Co.); an address in obstetrics, by Dr. Carlton C. Frederick, of Erie Co.; an address on The Medicine of the Classics, by the Hon. Charles H. Truax, LL.D., of New York; Expert Medical Testimony, or the Physician as a Witness, by Dr. Martin Cavana, of Madison Co.; Some Observations on Bone and Skin Grafting, by Dr. Benjamin M. Ricketts, of Ohio; Mental Therapeutics, by Dr. Henry D. Didama, of Onondaga Co.; Leprosy, by Dr. Joseph C. Greene, of Erie Co.; The Curability of Pulmonary Tuberculosis, by Dr. Hermann M. Biggs, of New York Co.; Preventive Medicine, by Dr. Henry C. Van Zandt, of Schenectady Co.; The Use and Neglect of Bloodletting, by Dr. Homer O. Jewett, of Cortlandt Co.; A Medico-legal Study of Alcoholic Daze, Trance, or Hypnotism, by Dr. Simeon Tucker Clark, of Niagara Co.; The Psychical Aspects of Insanity, by Dr. John Shrady, of New York Co.; Tumors of the Orbit and Neighboring Cavities, by Dr. Charles Stedman Bull, of New York Co.; Test of Dugas in Dislocation of the Shoulder, by Dr. Frederick W. Putnam, of Broome Co.; Early Infant Viability, with Management of Cases, by Dr. Henry C. Hendrick, of Cortlandt Co.; Scarlet Fever in the Puerperium with Cerebral Hæmorrhage and Hemiplegia, by Dr. C. S. Allen, of Rensselaer Co.; Alcoholism as a Vice, and as a Result of Inherited or Acquired Brain Disease, by Dr. Isaac de Zouche, of Fulton Co.; An Office Battery, by Dr. William H. Robb, of Montgomery Co.; In Abortion, What of the Placenta after the Second Stage, by Dr. Darwin Colvin, of Wayne Co.; Cysts and Cystic Formations—their Pathology, Diagnosis, and Treatment, by Dr. Thomas H. Manley, of New York Co.; Functional Disorders of the Nervous System of Women, by Dr. Timothy J. McGillicuddy, of New York Co.; The Feeding of Infants, by Dr. John P. Garrish, of New York Co.; and A Case of Craniotomy, with Remarks, by Dr. James W. Guest, of New York Co.

Alcohol and Childhood.—"We most decidedly and heartily give our support," says the *Lancet*, "to the doctrine that, as a rule, children and young people do not need alcohol, and are much better without it. Their appetites are good, their cares few, and the more simply they live the better. Anything that can be done in board schools, and in public schools too, for that matter, likely to promote a thorough and intelligent independence of alcohol, should be encouraged. But it should be well done. The more moderate and medical the statement of the case the better. Young people resent intemperance in teetotalers as well as in other people. It must be remembered, too, that the real way to make children temperate is by setting them a good example at home. If children see alcohol produced in all shapes, and at all hours, and for every visitor at home, or if they are sent out as messengers twice or thrice a day to the neighboring 'public,' all the teaching of the schools will go for nothing."

The Transfer of Public Insane Patients to State Hospitals.—The statute having made it the duty of the president of the State Commission in Lunacy to prescribe regulations governing the transfer of public insane patients from their homes or from poor-houses to State hospitals by Superintendents of the Poor, and concerning the clothing of said patients, he has issued the following order:

1. That all County Superintendents of the Poor or town, county, or city authorities, before sending a patient to any State hospital, see that said patient is in a state of bodily cleanliness and provided with the following clothing, to wit: (*a*) One full suit of underclothing. (*b*) One full suit of outer clothing, including head wear and boots or shoes.

Between the months of November and April, both inclusive, there shall be provided, in addition to the foregoing, suitable overcoats for the men patients and suitable shawls or cloaks for the women patients, also gloves or mittens. Considering the great danger, always present, of the introduction of contagious or infectious diseases into institutions where large numbers of people are congregated, and to avoid, so far as possible, the introduction of such diseases by means of wearing apparel, the clothing above provided for must in all cases be new.

2. In traveling by rail, patients must not be compelled to ride in smoking or baggage cars, except in the case of men patients who may be so violent, profane, or obscene as to render their presence in ordinary passenger coaches offensive. If any portion of the route is necessary to be traversed by team, a covered conveyance should, unless impossible, be provided. The shortest practicable route should be selected; the hour of departure should be timed, so far as possible, so as to avoid the necessity of stopping over night on the journey and so as not to reach the hospital at an unseasonable hour. Whenever practicable, a notice in advance, by writing or telegraph, should be sent to the medical superintendent of the hospital of the coming of the patient. In cases of violent patients a sufficient number of attendants should be provided to control their actions without resorting to the use of mechanical restraints, such as straps, ropes, chains, hand-cuffs, etc.; quieting medicines should not be given to such patients except upon the prescription of a physician. If it becomes necessary to remain over night or for a number of hours at a station on the route, patients are not to be taken to jail, police station, or lock-up. Food in proper quantity and quality, and at intervals not exceeding five hours, should be provided for patients, but no alcoholic beverages must be given unless upon prescription of a physician. Opportunity must be afforded for attention to the calls of nature, and the rules of decency must be observed. In case of the employment of extra attendants in conveying violent patients, care must be taken that they are of adult age and of good moral character. The provisions of the statute which require that a woman attendant shall accompany women patients when taken to State hospitals must be strictly complied with.

3. Any violation of the requirements of this order shall be promptly reported, so far as known to him, by the medical superintendent of the hospital to the State Commission in Lunacy.

4. This order shall take effect on the 1st day of October, 1890.

The New York Academy of Medicine.—At the next meeting of the Section in Ophthalmology and Otology, on Monday evening, the 20th inst., Dr. M. L. Foster will read a paper on Cyst of the Lacrymal Gland, Mr. James Prentice will show Prentice's prismometer, and Dr. H. D. Noyes will open a discussion on Hæmorrhage into the Vitreous following Operations.

At the next meeting of the Section in Theory and Practice of Medicine, on Tuesday evening, the 21st inst., Dr. G. R. Lockwood will read a paper on Acute Hæmorrhagic Purpura.

At the next meeting of the Section in Obstetrics and Gynæcology, on Thursday evening, the 23d inst., Dr. Ralph Waldo will read a paper on Pregnancy complicated by Circumuterine Inflammatory Deposits, and Dr. G. M. Edebohls will read a paper on Exploratory Puncture of the Female Pelvic Organs.

At the next meeting of the Section in Laryngology and Rhinology, on Tuesday evening, the 28th inst., Dr. C. H. Knight will read a paper entitled A Sequestrum removed from the Nasal Fossa by Ronge's Method, and Dr. D. Bryson Delavan will read a paper on The Surgical Treatment of Tubercular Laryngitis.

Prostatic Hypertrophy.—In a paper presented to the Mississippi Valley Medical Association at the recent meeting in Louisville, Dr. William T. Belfield, of Chicago, collects 133 cases of operations upon the hypertrophied prostate, including 8 of his own, as follows: 41 by perineal incision, mortality 9 per cent.; 88 by suprapubic cystotomy, mortality 16 per cent.; 4 by combined perineal and suprapubic incision, none fatal.

In fifty-six of these cases the essential facts before and after operation are furnished. The patients had been the subjects of cystitis and dependent upon the catheter for periods varying from one to ten years. In all the cystitis was cured; in thirty-eight (two thirds) voluntary urination was restored and continued during the time of observation, six months to two years and a half; in eighteen this function was not recovered.

Fifteen of these fifty-six cases were complicated with stone; excluding these—since it might be objected that the cure resulted rather from the calculus extraction than from the prostatic operation—there remained forty-one cases of uncomplicated prostate operations; of these, thirty-two patients (four fifths) recovered the power of urination, and in nine this ability was not recovered.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Original Communications.

A CONTRIBUTION TO THE STUDY OF APPENDICITIS.*

BY LEWIS A. STIMSON, M. D.,
ATTENDING SURGEON OF THE NEW YORK AND BELLEVUE HOSPITALS; PROFESSOR OF SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

INFLAMMATION of the vermiform appendix is an affection that has received especial attention during the last few years—an attention that has greatly increased the extent and accuracy of our knowledge of its various forms and mode of development, and our ability successfully to deal with it. A large part of this advance in our knowledge of the subject is the result of the labors of American physicians and surgeons, and one of the most notable papers that have appeared of late upon this, or indeed upon any surgical topic, is the one read by our associate, Dr. McBurney, before this society, November 13, 1889, under the title of Early Operative Interference in Disease of the Vermiform Appendix, and published in the *New York Medical Journal*, December 21, 1889.

It was not merely that he presented an important number of cases successfully operated upon in the early stage, and a number much larger than had been reported by any other surgeon, but, much more than that, he presented new and important information concerning the pathological processes of the early stage, the varying conditions of the appendix, the position and time of appearance of pus, the relation or absence of relation between the symptoms and the pathological conditions, and, above all, pointed out the means by which the presence of the disease might be recognized at the very outset. Perhaps the most valuable result of the publication of Dr. McBurney's paper has been the readiness and certainty with which the disease is now recognized, and the wide extension that has been given to this addition to our diagnostic resources. This is shown by the great increase in the number of recognized cases and in those that are referred to surgeons for operation. This is strikingly shown by a comparison of recent experience with that of the past. When Dr. Sands wrote his first paper on appendicitis, eight or ten years ago, he mentioned as a surprising fact that he had seen twenty-nine cases in the course of the preceding twenty years; probably some of us have seen nearly an equal number in the last year. As there is no reason to suppose that the affection is more frequent today than it was in the past, the inference is unavoidable that formerly many cases passed unrecognized. The fatal cases were called peritonitis or intestinal obstruction; the mild ones were thought to be gastritis, or gastro-enteritis, or intestinal colic.

This increase in the number of recognized cases is all the more valuable because it is not merely a duplication of past experience, but, on the contrary, is made up of cases observed in earlier stages and under different conditions. For this reason, and because of the need of establishing principles of treatment based upon the new knowledge, it is desirable that recent individual experience and results should be made known in order that enough material may be at our disposal to permit trustworthy deduction and generalization.

I desire, therefore, to present this evening a report of the cases—twenty-one in number—that have come under my observation since November, 1889. Four of the thirteen operative cases have been previously reported to the society. For convenience of reference, the cases have been arranged in groups according to the method of treatment instead of chronologically.

CASES NOT OPERATED UPON.

CASE I.—John E., thirty years of age, was brought to the Chambers Street Hospital, February 27, 1890. Four days previously he had a chill, followed by pain in the abdomen, persistent nausea, and fever. A physician had seen him on the third day and found his temperature 101·7°. No movement of the bowels since the beginning of the attack. He had had a similar attack two or three years previously. On admission, his temperature was 98° in the rectum, pulse 130 and weak, abdomen greatly distended and painful, especially on the right side; patient apathetic. The question of appendicitis was raised but not positively answered. The patient's condition was so desperate that no operative measure was deemed justifiable, except an enterotomy for the relief of the (functional) obstruction. It showed the small intestine deeply congested and largely distended to a point six inches above the ileo-cæcal junction; below that point it was empty; no kink or mechanical obstruction was seen. The contents of the intestine escaped freely through the incision, but the patient died a short time afterward—February 28th.

The autopsy showed general peritonitis without liquid or fibrinous exudation, the appendix deeply congested and apparently gangrenous at its apex. Microscopical examination showed catarrhal inflammation of its mucosa; there was no perforation.

CASE II.—On April 28, 1890, I was called by Dr. Wells, of New Rochelle, to see Henry R., thirty years old, who had been attacked, April 23d, with violent pain in the right iliac fossa. The diagnosis of appendicitis was made and the pain soon relieved by morphine; the apparent convalescence had been abruptly interrupted at 10 A. M., April 28th, by a recurrence of the pain, so severe that a grain and a half of morphine were administered hypodermically within three hours. I saw him at 4 P. M.; he had then no pain except on pressure, was cheerful, but his surface was dusky and cool, his lips bluish, his pulse 150, and his rectal temperature 105·5°, although in the mouth it was only 99·25°. The abdomen was tense and distended; deep resistance and pain on pressure in the right iliac fossa; a soft, irregular mass, hard and tender on its right side, could be felt through the rectum behind the bladder. The patient was clearly moribund, and died four hours later.

CASE III.—On May 18th I was called to Connecticut to see a friend, a man thirty years old, who had been ill for nearly a month with constant but not severe pain in the right iliac fossa, occasional nausea, and some fever. I found him free of fever but very weak, with marked tenderness and slight deep induration at a point midway between the umbilicus and the right anterior superior spine of the ilium.* For a few days previ-

* Read before the New York Surgical Society, October 8, 1890.

* For the sake of brevity, and as a proper recognition of the value of this symptom, I shall speak of this point as "McBurney's point."

ously there had been at this point a swelling that distinctly raised the anterior abdominal wall. The tenderness persisted at intervals until August, and was increased by free movements of the right thigh.

Case IV.—James H., aged twenty-four, was attacked May 17th with nausea and diffuse abdominal pain, followed by fever, which persisted until May 20th, when I was asked to see him. There was marked tenderness on pressure at McBurney's point; temperature 100°. There was a clear history of a very sharp attack, diagnosticated as perityphlitis, five years before. Having in view the possibility of an operation, I sent the patient at once to the New York Hospital. After the condition had been explained to him he desired the operation, but, as he was improving, I advised delay; the next day he was much better, and shortly afterward was discharged. He declared that if the trouble recurred "he would have that thing out"; it did recur, and he reappears in the group of cases treated by laparotomy.

Case V.—Henry D., aged twenty-one, was admitted to the Chambers Street Hospital, June 15, 1890, complaining of pain in the abdomen and nausea. The McBurney point was well marked; no deep induration; temperature, 101·5°. He was kept in bed on low diet, and improved so rapidly that he was discharged in three days.

Case VI.—On September 23, 1890, I was asked by Dr. Partridge to see Mr. H. R., twenty-five years old, who had been attacked with abdominal pain on the preceding afternoon. The pain had become quite severe by morning, with nausea and a slight chill at noon. I saw him at 3 P. M. Temperature, 101·75°; pulse, 102; abdomen quite tense on the right side and painful on pressure at and below McBurney's point. No recognizable induration. He had had two similar but less severe attacks within the preceding ten weeks.

At 9 P. M. his temperature was 100·25°, pulse 74. The following day the temperature had fallen to 99°, and on the 25th it was normal and the tenderness much less. He was kept in bed and on a light diet for six days, and then discharged. There was still slight tenderness in the iliac fossa on pressure.

Case VII.—James G., about forty years old, while under treatment in the New York Hospital for a compound fracture of the arm, had a rise of temperature, nausea, and considerable abdominal pain; McBurney's point well marked. The following day the fever and nausea had ceased; the local tenderness had diminished, and it entirely ceased in a day or two.

In the following case the diagnosis may be questioned.

Case VIII.—An unmarried lady, thirty-two years old, has been practically disabled for several years by recurrent attacks of pain in the abdomen, especially on the right side, accompanied by nausea, but usually without fever. Five years ago she was treated by an eminent gynæcologist for these attacks, which he thought might be due to an ovaritis. An equally eminent physician, whom she subsequently consulted, diagnosticated an inflammation of the ascending colon and gave her some relief. The attacks were always severe, the pain beginning in the right iliac fossa, and sometimes radiating up the back; they lasted for days, and sometimes for weeks with less severity. I saw her in August during an attack and found McBurney's point perfectly well marked. I believe it to be a case of recurrent appendicitis, and expect that before long an operation will demonstrate it.

Cases treated by Operation. Simple Evacuation of an Abscess.

Case IX.—D., ten years old, was admitted to the New York Hospital on November 25, 1889. Two weeks previously he had been seized with severe pain in the right iliac fossa, nausea, and fever; during the second week a swelling was noticed in the right iliac region. On admission, there was a large fluctuating swelling in the right iliac fossa, over the center of which the skin was red and adherent. Temperature, 101·5°. An incision was made over the prominent part of the swelling and a large quantity of pus evacuated. On December 28th discharged cured. The boy has been seen recently, and has remained well.

Case X.—Mary K., aged twelve years, admitted to the New York Hospital, in June, 1890, with a perityphlitic abscess, which was opened by an incision along the outer part of Poupart's ligament and the adjoining crest of the ilium. The case came under my care July 1st, and then had a fæcal fistula in the line of the incision, which still persists.

Case XI.—Dr. James E., about thirty years old, was attacked on April 10, 1890, with severe pain in the right iliac fossa and vomiting. This was the sixth attack in three years. The previous attacks had been treated by the internal administration of castor-oil and belladonna, and had lasted only one or two days, ceasing promptly after the bowels moved. I saw him on the second day, when he was feeling better and was confident the attack had passed. The evening of the 12th, while at stool, he had the sensation of something giving way in the lower part of the abdomen. He said it felt as if something tore for a length of about four inches, and this was followed by great rectal tenesmus. He summoned an ambulance to take him to the New York Hospital, and notified me on the following morning. Dr. McBurney kindly saw him with me at my request. Temperature, 101°, the patient looking very ill, and quite dazed by a small amount of morphine taken the previous evening. Marked tenderness and some fullness in the right iliac fossa at and below the level of the anterior superior spine. The finger in the rectum found a bulky swelling at and above the region of the prostate, extending from side to side of the pelvis, rather hard and tender on the right side, soft and depressible high up in the center. A hypodermic needle, introduced into this swelling, brought thin, offensive pus.

Ether, anus dilated, and an incision made through the anterior wall of the rectum, evacuating a large amount of thin pus. The finger introduced through the incision passed into a cavity behind the bladder, undoubtedly the cavity of the peritonæum. A large drainage-tube was inserted and retained for three days, then escaping spontaneously during a movement of the bowels induced by a saline purge.

April 18th.—Patient returned to his home.

May 7th.—Some thickening can be felt through the rectum, and a very little in the right iliac fossa.

The transient character of the five previous attacks naturally gave him the impression that the sixth would be as easily recovered from, and yet it is clear that the delay seriously imperiled the patient's life.

Cases treated by Laparotomy, with Opening of the General Peritoneal Cavity.

In all but one of these cases the incision was made along the outer border of the rectus from the level of the umbilicus nearly to the center of Poupart's ligament. The appendix was tied with catgut close to the cæcum and cut away; the stump was cauterized with pure carbolic acid; the adjoining intestines were carefully protected during the operation by flat sponges and cloths held against them by long, broad retractors; a drainage-tube and packing of iodoform gauze were used in all cases and usually removed on the fourth or fifth day. The external wound was closed for two thirds or three fourths of its

length. Absolute diet was maintained for twenty-four hours, and then small quantities of milk were given. The microscopical examination of the removed appendices was made by Dr. Ferguson and Dr. James at the laboratory of the New York Hospital.

Case XII.—John M., twenty-two years old, was admitted to the Chambers Street Hospital, October 25, 1889, complaining of severe pain in the right iliac fossa. Temperature, 99°. There was some rigidity of the abdomen on the right side, but no dullness or tumor. McBurney's point well marked. He gave a history of two attacks, fourteen months and three years previously.

Operation forty-eight hours after the beginning of the attack. The appendix was closely adherent through its whole length to the mesentery of the ileum, and so completely imbedded in new tissue that it was found and removed with much difficulty. There was no pus. Microscopical examination showed the wall of the appendix studded with small round cells, and the structure of the mucosa entirely lost. Recovery followed without incident.

Case XIII.—Christopher H., twenty-three years old, admitted to Chambers Street Hospital, November 29, 1889, complaining of nausea and violent pain in the abdomen, especially on the right side. Temperature, 103°. I transferred him to the New York Hospital, and operated fifty-five hours after the beginning of the attack. The appendix was prominent below and behind the cæcum, deeply congested, and about an inch long and three quarters of an inch thick at its base. As the cæcum was raised pus escaped, to the amount of about two drachms, from around the base of the appendix. It was caught on sponges, and the region lightly washed with a bichloride solution. The appendix was then removed. From its apex a stout cord of connective tissue extended upward, and was continuous with the tissues of the floor of the fossa. The patient made an uneventful recovery.

Case XIV.—Lorenzo M., twenty-three years old, admitted to the Chambers Street Hospital, January 21, 1890. Ten days previously he had been seized with severe abdominal pain and nausea, which had persisted in less degree and had been accompanied by fever. A firm, very sensitive swelling could be felt in the right iliac fossa, beginning an inch above Poupart's ligament and extending upward farther than it could be followed. It was dull on percussion, with resonance below, above, and on its inner side. Temperature, 101·5°. On making the usual incision there were found no infiltration of the abdominal wall, no adhesions, no injection of the peritonæum, no effusion. The cæcum and ascending colon were empty and raised upon a firm mass attached to the floor of the iliac fossa; the ileum and its mesentery were normal, and could be readily followed to the junction wth the cæcum, but the appendix could not be found. While holding up the cæcum I saw pus exude through a minute opening in the lower end of the mass just mentioned. A sponge was placed against it, the adjoining intestines protected by flat sponges, and then the minute opening was enlarged, giving exit to several ounces of fœtid pus and gas: the finger could then trace the cavity of the abscess upward and backward behind the colon as far as the finger could reach. The appendix seemed to be imbedded in the lower part of the wall of the abscess and was not removed.

A drainage-tube was introduced into the abscess, and the portion lying between the abscess and the parietal incision was rather thickly surrounded with a packing of iodoform gauze. Gauze was also packed over the cæcum and between it and the small intestine, as a protection in case infection by the pus had occurred at that point. This gauze was removed after three days, that around the tube at the end of a week. The patient made an uneventful recovery.

Case XV.—James R., eighteen years old, was brought to me, March 31, 1890, by Dr. White, of Franklin, N. Y., with a history of four attacks of appendicitis within a year. The first attack lasted four days; the second, in September, 1889, was more severe; the third, in December, less severe; and the fourth, in March, again more so. Dr. White had seen the patient only in the last attack. His description of the symptoms, which included the McBurney point, left no doubt of the correctness of the diagnosis. I sent the patient to Bellevue Hospital and operated the next day.

The appendix was adherent to the cæcum and omentum; its terminal inch was as large as the end of my little finger; the remainder, an inch and a half to two inches long, was the size of a lead-pencil. It was removed and the patient was discharged, cured, at the end of a fortnight. The appendix contained no concretion and no pus; the cavity of its dilated end was shut off by a tight stricture; the mucosa was thickened and pulpy.

Case XVI.—John McG., seventeen years old, was admitted to the Chambers Street Hospital, April 17, 1890, complaining of severe pain in the right iliac fossa, which had begun a few hours before. In January, 1887, he had been in the hospital for three weeks suffering with peritonitis caused by the passage of the wheel of a wagon across his abdomen. Temperature 102°. Marked tenderness on pressure and some resistance in the right iliac fossa. I operated the next day. The subperitoneal tissue in the line of the incision was œdematous, the omentum adherent at points to the anterior abdominal wall; the free end of the appendix was almost in contact with the anterior wall, the cæcum lay above it, and a loop of the ileum lay on its inner side closely adherent to it, to the cæcum, and to the floor of the fossa. These adhesions were old and thick; the appendix was deeply congested. The removal of the appendix was difficult, because of the adhesions and because of its position in the sort of deep, narrow pocket formed by the adherent intestines; it was tied two inches beyond its tip, apparently quite close to the cæcum. Uneventful recovery.

Case XVII.—Dr. Charles W., aged thirty-two, was attacked, May 26, 1890, with nausea, which grew worse during the evening and was accompanied by abdominal pain. As there was no movement of the bowels and no escape of flatus during the night, he feared intestinal obstruction, and sent for me the following morning. There was pain on pressure and dullness on the left side of the abdomen; the right iliac fossa was free. Temperature between 101° and 102°. A dose of castor-oil induced a copious movement, which contained a considerable quantity of undigested soft-shell crabs that had been eaten the previous day. The nausea persisting, I transferred the care of the case to Dr. J. W. McLane.

A week later, June 3d, I was again called; the fever had been constant, there was marked pain and an ill-defined tumor in the right iliac fossa, and the skin above the crest of the right ilium was red and thickened. The patient was evidently very ill. Not wishing, for personal reasons, to operate, I asked Dr. McBurney to do so. The operation was done June 4th. An exploration of the reddened area above the ilium showed that the wall was not invaded and not adherent to the adjoining mass; the usual incision was then made in front. A small amount of pus was found behind and at the outer side of the cæcum, and was carefully removed on sponges. The appendix was not seen, and it was thought best not to break up adhesions to seek for it. The operation was done with the delicacy and precision that characterize the operator, and no precaution was neglected that might have contributed to the safety of the pa-

tient. But the septicæmia was not checked, the discharge was free and very offensive, and he died forty-eight hours after the operation.

Case XVIII.—James H., aged twenty-four. The previous history of this patient has been given above (Case IV). On June 29th he had another attack, less severe than the one in May, and, as I was temporarily absent from the city, he entered the New York Hospital and sent me word that he wished to have his appendix removed. When I saw him, July 1st, the attack had almost ceased, the temperature was normal, and the tenderness on pressure slight, but he still desired the operation.

The appendix arose from the antero-lateral aspect of the cæcum and thence curved inward and backward, its apex being closely adherent to the peritonæum of the fossa; the distal half was firmly bound down by adhesions, and there were some recent ones along its curve. It presented two constrictions that divided it into nearly equal thirds, and was not distended; it contained no concretions; its mucosa was almost completely destroyed by round-cell infiltration. The patient was discharged, cured, July 15th.

Case XIX.—Mrs. K. (Stamford, Conn.), thirty-five years old, the mother of seven children and three months pregnant, was seized with intense abdominal pain on the right side at 1 P. M., July 31, 1890; it was so severe that between three and ten o'clock she received a grain and a half of morphine hypodermically. Tenderness on pressure appeared to be most marked at McBurney's point, and extension of the right thigh was somewhat painful, but, as the patient had lost blood rather freely from the uterus three times during her pregnancy and some thickening could be felt through the vagina on the right side, her physician, Dr. A. M. Hurlbutt, thought it might be a ruptured extra-uterine-gestation sac. I saw the patient at 1 A. M. She had rallied, the pain was controlled by the morphine, but the temperature had risen to 101°. The abdomen was rigid, resonant throughout, and moderately distended. The previous history was negative except for several transitory attacks of sharp pain low down in the abdomen during the preceding three or four years, none of which had compelled her to take to bed.

I did not think it was a case of ruptured extra-uterine pregnancy, but the existence of an acute spreading peritonitis was beyond doubt, and I advised immediate operation to remove the cause if possible. I chose the median incision, believing that the appendix could be removed through it if necessary, and that it might be of advantage if the peritonitis should prove to be due to some other cause.

The operation was done at 2 A. M., with the assistance of Dr. Hurlbutt, Dr. Pierson, and Dr. Hungerford. As soon as the peritoneal cavity was opened a considerable amount of turbid serum containing flakes of lymph escaped, and, on raising the right side of the incision, the appendix appeared; it was brightly congested; its apex was directed forward and inward and almost in contact with the abdominal wall; it lay behind and in contact with the right ovary, the point of contact being at the junction of its basal and middle thirds, and at this point was a dark slough a quarter of an inch in diameter; around the slough and on the adjoining surface of the ovary was a narrow white zone of fibrin. The neighboring peritoneal surfaces were congested; there were no adhesions.

The appendix was tied at its base and removed with great ease, the adjoining peritonæum lightly sponged off, a drainage-tube and iodoform gauze packing introduced, and the incision closed in great part. Recovery followed without interruption. The appendix was three inches long and as large as the little finger; its wall was very thick, the mucosa in a condition of catarrhal inflammation; it contained only a small flake of soft fæces. On the basal side of the slough, which was perforated at its center, was a marked diaphragmatic contraction with a minute central opening. The mucosa covering this constriction was not destroyed, and it did not appear to be cicatricial.

Case XX.—Robert R., aged twenty-eight, a pilot, was attacked with very severe pain in the abdomen on the evening of September 22, 1890, while at sea; during the two preceding days he had had occasional slight pains. The pain continued with nausea through the following day and night, and he was brought to the Chambers Street Hospital on the morning of September 24th. I saw him at 12.30 P. M. He gave the history of a similar attack in the preceding April. His temperature was 103°, pulse 145, abdomen tense and resonant throughout but somewhat dull in the right flank, and was very painful on pressure in the right iliac region and the left hypochondrium. His voice was strong, his mind clear and calm, and, although the condition seemed desperate, yet I was encouraged, by the success in Case XIX and by the absence of the signs of profound septic intoxication, to make the attempt to save him. Other engagements compelled a delay until 3.30. The pain in the left hypochondrium had then ceased; rectal temperature, 104°; pulse, 165. As soon as the peritoneal cavity was opened several ounces of thin pus escaped, coming in great part from the region of the right flank, but also from the mesial side of the incision and the floor of the fossa. There were no limiting adhesions, and the distended intestines were held back with difficulty. The appendix lay transversely, its apex below the brim of the pelvis; it was much enlarged and was bound down by light adhesions, which gave way readily on slight traction. I transfixed its mesentery close to the origin of the appendix and passed two catgut ligatures, one about the narrow mesentery, the other about the appendix, and cut away the latter. The pus was removed by sponging, a drainage-tube was passed upward on the outer side of the colon, and iodoform gauze was packed above, below, and to the inner side. The incision was partly closed by a suture at its center and one at each end.

The appendix, two inches and a half in length, somewhat flattened, and more than an inch broad near its free end, showed three sloughing perforations—one close to the line of section, one at the apex, and one midway between the others. Within it and corresponding to the first perforation was an enterolith a third of an inch in diameter; the wall was thick, the mucosa sloughy, and showing drops of pus at a few points.

At 10 P. M. the pulse had fallen to 130, the temperature to 102·5°; the next morning the temperature in the rectum was 100·4°, pulse 135, and the patient cheerful and apparently better, but the nausea persisted. At 6 P. M. the temperature in the rectum had risen to 104·6°, the pulse to 150; a saline purge and enema had proved ineffectual. Two hours later I went to him with the intention of opening the abdomen in the median line and draining the left side of the cavity if the symptoms called for it; but I found him easier, his temperature a little lower, and no signs of an effusion within the cavity; there was some tenderness on pressure with the finger in the rectum. I withdrew part of the packing; it was moderately wet and odorless.

September 26th.—He seemed better in the morning, but the rectal temperature was 104° and the pulse 150 and very small. At 10.30 the temperature was 105·5°. During the afternoon he was delirious at intervals; rectal temperature at 3 P. M. 107°. He died at 6 P. M. with a temperature of 107·8°.

Autopsy eighteen hours after death. The packing of the wound had been withdrawn immediately after death, and the incision closed by sutures. Abdomen largely distended. On opening the abdominal cavity, liquid fæces and gas escaped in large quantities; they came from a linear opening an inch long near the middle of the small intestine, the loop lying in the right

hypochondrium, the edges of which showed no traces of inflammation. As the cavity in the loin occupied by the drainage-tube and the upper packing was not shut off from the general cavity by adhesions, and as nothing came from it when the packing was removed and the incision sewed up after death, I can not think this rupture and effusion could have occurred before death. It is barely possible that it was a cut made in opening the abdomen at the autopsy. No pus could be recognized in the liquid, and there was no injection of the general peritoneal cavity, no adhesions, no coating of fibrin upon it. The stump of the appendix was completely covered in by adhesions. In the true pelvis on the right side was a closed collection of sweet, thick pus, estimated at two ounces; it surrounded the point on the wall from which the perforated apex of the appendix had been removed. It seems not improbable that if the packing had been pushed farther down in this direction, suppuration might have been arrested there, as it apparently had been elsewhere. The terminal ten or twelve inches of the ileum ran down into the pelvis, was adherent to its wall, and formed part of the wall of the abscess; it was darkly congested and thickly coated with fibrin in places, and empty. The cæcum and ascending colon contained only a small amount of dark semi-solid fæces, showing that something had completely prevented the passage of the contents of the small intestine downward. No mechanical obstruction could be found.

Case XXI.—Hermann F., aged twenty-two, admitted to the Chambers Street Hospital, September 30, 1890. He had been ill for two weeks with continuous nausea and vomiting and severe pain in and near the right iliac fossa. No history of any previous attack. Temperature 102 4°. Abdomen not distended or rigid. A well-marked swelling extended from the pubes nearly to the umbilicus, and from an inch to the left of the median line to three inches to the right of it, not reaching to the right spine of the ilium by more than an inch; maximum tenderness begins an inch below McBurney's point and extends downward and inward. Under ether the swelling is hard, irregular, and slightly movable laterally.

Operation at 2 P. M. The omentum covered the mass and was closely adherent to it and to the anterior abdominal wall on the mesial side of the incision, but not to the cæcum. The anterior longitudinal bundle of the cæcum ran inward to the base of the mass. On gently separating the latter from the floor of the fossa, exit was given to a large quantity of fœtid pus, estimated at six ounces, and to a fæcal concretion half an inch long and nearly as thick as a lead-pencil. The bleeding from the wall of the abscess was free. Large packing of iodoform gauze; the incision was partly closed by a suture at each end and a loosely-drawn central one. The temperature fell that evening to 99·6°; the bowels were moved by enema October 2d, and the gauze was removed October 3d, a light, fresh packing being substituted.

To-day, October 8th, the temperature is normal, the abdomen flat and insensitive, the abscess is discharging moderately, and the incision is closing.

In eight of these cases the removal of the appendix gave the opportunity to examine it directly and investigate the *cause* of the morbid process. Contrary to a widely held opinion and perhaps to the experience of others, in only one of them was a foreign body or a fæcal concretion of sufficient size to have been a factor in inducing the inflammation found. The oyster-shell and grape-seed of tradition must disappear as causes, or at least must be freely supplemented by others. But in all cases we find a marked inflammation of the mucosa, and one that in some cases had almost obliterated its structure by studding it with round cells. Total or partial obliteration of the lumen was found in three cases; and in another, in which the appendix was short and considerably distended, it seems probable that there was a constriction between the point of excision and the cæcum; in one of these three cases the stricture was double, but not impervious. As the first two gave a history of previous attacks of considerable severity, I deemed these strictures the result of cicatricial contraction, but in the other one (Case XIX) there was a history of many transitory attacks of pain, but of none lasting for any length of time and accompanied by fever, and the stricture itself was not cicatricial but was covered by a normal mucosa. It seems probable, therefore, that the cause may sometimes lie in a congenital defect, a narrowing due to a developmental aberration. It would be instructive to know in what proportion of all autopsies such stricture of the appendix is present.

It can hardly be doubted that the combination, when present, is an important factor in provoking or increasing the inflammation, and, by preventing the escape of the contents of the appendix, in inducing perforation. Cases have been reported in which the appendix was literally a bag of pus, an abscess upon the point of breaking, and for such a condition a total occlusion of the lumen on the proximal side is necessary. Yet perforation is not always due to obstruction and distention; in Case XIX the obstruction was not complete, and there was no distention, yet a slough a quarter of an inch in diameter had formed without any warning symptoms, and the attack began apparently with its separation.

In Case XVII the appendicitis followed an attack of gastro-enteritis induced by an error in diet, and the case is noteworthy for the prompt appearance of septicæmia and its rapid advance to a fatal termination without peritonitis and notwithstanding the evacuation and drainage of the small abscess. In connection with this apparent relation between enteritis and appendicitis I may refer to those occasional cases in which an error in diet is habitually followed by a transient attack of appendicitis, one marked by pain but usually free from fever, and of only a few hours' duration. On the hypothesis of a constriction of the appendix and of a catarrhal inflammation of the mucosa such attacks can be readily explained.

Remembering that the mucosa of the appendix contains an exceptionally large proportion of solitary and agminated follicles, it occurred to me that appendicitis might, theoretically, be expected sometimes to occur as a sequela of typhoid fever. My own experience contains only one case in which such a connection might have existed—a case of typhoid fever the convalescence from which was interrupted by a return of fever with abdominal pain, followed after a few weeks by pyæmia and death. The autopsy showed a small collection of pus about the appendix, a suppurative portal phlebitis, and multiple abscesses of the liver. Since the possibility of such a connection first occurred to me, about a year ago, I have noticed the report in the journals of two cases in which appendicitis immediately followed an attack of typhoid fever.

The *course* of the affection, when not interrupted by operation, is shown or indicated in nineteen of my twenty-one cases, and if to these are added the previous attacks in the same patients (excluding Cases VIII and XIX), we have a total of thirty attacks. Of these, twenty recovered and two died, without operation; pus was found in nine; in three of these it formed a large abscess which was opened without exposure of the general peritoneal cavity, and with the formation of a persistent fæcal fistula in one; in four the collection of pus was removed by laparotomy, with one death; in two, general peritonitis occurred in consequence of perforation, with one death and one recovery after laparotomy. Two cases (XII and XVI) throw no light upon the probable course, because the process was cut short by an early removal of the appendix.

The pus in all the cases, with possibly one exception, was intraperitoneal; in the possible exception (Case XIV) it lay between the layers of the mesocolon, and it may be deemed an open question whether it originally formed there or reached that position by perforation of the peritonæum after having formed about the appendix; the latter organ was not recognized, being apparently imbedded in the wall of the abscess.

It is of interest to note that in one case certainly (XII), and in two others probably (XIII and XVI), pus formed about the appendix without perforation or sloughing of that organ; and also that a fatal septic peritonitis was set up (Case I) without perforation of the appendix or the previous formation of pus about it. In Case XIII pus was found, without perforation, at the beginning of the third day, and in the same length of time in Case XI a large abscess appears to have had time to form and rupture.

The uncertainty of the course is strikingly shown in Cases II and XIX; in the former, convalescence, that had apparently been progressing satisfactorily for several days, was suddenly interrupted by a violent recurrence that proved fatal in ten hours; in the latter, a slough formed in the wall of the appendix without having given rise to any symptoms that attracted the patient's attention, and its perforation set up a general peritonitis that would, I think, have proved fatal in a few hours if it had not been arrested by operation.

Eight of the patients (exclusive of Case VIII) had had previous attacks, most of them quite severe. In one (I) the second attack proved fatal by septic peritonitis without perforation or suppuration; in another (XX) the second attack proved fatal by perforation; in another (XIX), after many slight attacks, perforation took place and nearly proved fatal; in Case XI, after five previous attacks, a large abscess formed and was opened through the rectum after the patient's life had been gravely jeopardized. In Case XV, operated upon after the cessation of the fourth attack, the terminal inch of the appendix was shut off by a constriction and so distended that its ultimate suppuration, if it had been left to itself, seems highly probable. In the sixth (XVIII) there were two tight constrictions of the appendix, but no distention. In the seventh (XII) the appendix was buried under adhesions, and in the eighth (VI) no operation was done. These histories indicate that the danger is greater in patients who have had previous attacks, and that the easy inference that because they have escaped once or twice or thrice they may therefore be trusted to do so again, is not well founded.

The course of an attack that gets well under medical treatment is ordinarily as follows: It begins with pain more or less severe, at first central or general, but soon localized or with maximum severity in the right iliac fossa, and accompanied or soon followed by nausea. The temperature rises and may reach 102° at the end of twenty-four hours, but during the second day it falls, although the tenderness on pressure or coughing persists, and by the third or fourth day the temperature is normal and the tenderness less. Traces of the latter may remain for a week or two.

In cases that suppurate, with or without a perforation protected by adhesions, the temperature continues to rise, or is maintained after the second day, and distinct resistance or a well-defined tumor is recognizable on deep palpation in the right iliac fossa. This tumor is constituted at first, not by an abscess, but by agglutinated loops of intestine, and exploration of it with a hypodermic needle is very unlikely to yield pus.

Death may come through septicæmia after suppuration, by shock or acute peritonitis after perforation or rupture of an abscess, or by a septicæmia that apparently originates in a functional obstruction of the intestines. Two of the four deaths in this list of cases were apparently due to this latter cause, and the conditions found on autopsy were striking: the small intestine largely distended with liquid yellow contents down to a point within a few inches of the ileo-cæcal junction and empty beyond, with no recognizable mechanical obstruction at the point where the distention ceased. I recall another case in which the same conditions existed: a stab-wound of the abdomen, with four cuts in the intestine, which I closed by suture; the course of the case, until death on the sixth day, was that to which the name of intestino-peritoneal septicæmia has been recently given, and the autopsy showed the same distention of the small intestine ending abruptly in the neighborhood of the healed wounds in the bowel. This is a condition against which, when it is fully developed, we seem to be at present powerless, and which demands our most thoughtful attention.

Concerning the diagnosis I have but little to add. The localization of the maximum of pain, or of the only pain, on pressure at or very near the point indicated by Dr. McBurney, two inches from the anterior superior spine of the ilium on a line drawn from it to the umbilicus, has been constant, and, in pointing out this symptom, Dr. McBurney has rendered us a service which it is difficult to estimate too highly; it has made the recognition of appendicitis, in its early stages at least, easy for every one. In several cases I have found the point of tenderness a little lower, or that it covered a relatively large area downward. It may justly be objected that the appendix is not the only organ in the right iliac fossa that may be the seat of pain, but, except in the case of women, the objection appears to have no practical importance, and the disease is much less common in women than in men. An answer that seems to me to be entirely sufficient to the objection that the group of symp-

toms mentioned is not sufficient for the diagnosis is found in the fact that it has been tested in a very considerable number of operations and no error in diagnosis has yet been reported. It is, of course, understood that the value of this symptom is greater in the cases in which an abscess of considerable size has not formed or the abdomen is not greatly distended and rigid.

While the diagnosis is easy in the early stage, and also in the late one in which a large fluctuating tumor is present in the right iliac fossa, it may be surrounded by much uncertainty at other stages and in other forms. The case may not be seen until after the attack has lasted several days, and it may be impossible to obtain an intelligible account of the earlier symptoms; the abdomen is distended and rigid, vomiting is persistent, the bowels have not moved. Is it appendicitis, or one of the varied forms of intestinal obstruction, or a peritonitis due to some other cause? If there is a history of a previous attack, and if pain is found especially at McBurney's point, we may, I think, make the diagnosis with considerable confidence, especially in view of the relatively great frequency of the affection.

But the recognition of the existence of appendicitis is not all that is needed. We must also seek to know its character and probable development. Is it a simple catarrh that will resolve in a few days? will pus form, and, if so, can we safely await the evolution of the abscess? or is an unprotected perforation or the rupture of a small abscess about to occur? The aids to answering these questions are few and not very helpful, and yet the questions are of the utmost importance; upon the answer turns the choice between operative and expectant treatment; the issue may be life or death.

Upon the question whether suppuration will or will not occur, or whether it has not perhaps already occurred, we can, I think, find some guidance in the height and persistence of the fever. If the temperature is above 102° two days after the beginning of the attack, suppuration is, I believe, imminent or already present.

As to the imminence of an unprotected perforation, a perforation with immediate infection of the general peritoneal cavity, I know of no guide. We have seen it occur abruptly without the slightest warning in one case (XIX), and with only such warning as was contained in slight transitory pains during the preceding two days in another (XX).

The degree of the pain at the onset tells us but little. If very severe, it may be the sign of a perforation that has placed the patient's life in the greatest danger, or, as in a case reported to this society by Dr. McBurney last May, in which a grain and a half of morphine was required to control the pain, there may be no perforation, no peritonitis, no suppuration. Let me add, however, that severe pain occurring *in the course* of the affection has very great significance; it means the rupture of the appendix or of an abscess into the general peritoneal cavity.

Grievous as the conclusion may be, it must be admitted that we are wholly unable to distinguish at the beginning the case that will end in recovery, even if left to itself, from that which will put the patient's life in the greatest danger; we are even unable to assure the patient that before the door closes behind us he may not have passed into the very jaws of death. As Dr. McBurney said in the paper to which I referred at the beginning, there seems to be no better way of improving our methods of diagnosis than the exploratory incision; and he added: "If it can be shown by future experience . . . that the exploratory incision for inspection of the diseased appendix is much more free from danger than the expectant treatment, then there could be but one answer to the question, what is the best treatment?" As part of the material to be accumulated for that purpose, my list furnishes five operations in the early and doubtful stage without a death, and even without a moment's anxiety beyond that which belonged to the taking of the step.

Turning now to the question of *treatment*, we find, as already stated, twenty attacks treated medically, with eighteen recoveries and two deaths; but if to these we add those in which surgical aid was required at a later period in the case, we have twenty-eight attacks with four deaths. This is the most favorable showing that this group of cases can be made to give for medical treatment; if previous attacks are excluded, and only those taken which I saw, the record stands sixteen cases with four deaths, a mortality of 25 per cent., and ultimate resort to surgery in eight—exactly one half. Again, including previous attacks, in order to meet as far as possible the objection that the surgeon naturally sees an unduly large proportion of cases requiring operation, we have twenty-eight attacks, ten of which (adding the two deaths), or more than one third, required surgical treatment. It is to be remembered also that most of the surgeon's hospital cases have gone to the hospital, not specifically for operation, but for treatment, and that to that extent his experience is the same as that of the general practitioner. Further, this list contains cases to which I was called as a surgeon, but in which no operation was done.

In connection with this I will quote the statistics of a physician, Dr. Fitz,* seventy-two personal cases, the largest number yet reported. He says: "Seventy-four per cent. recovered and 26 per cent. died. About one half of them were treated medically, the other half receiving surgical treatment [presumably in the later stages of the affection]. Of those treated surgically, 40 per cent. died, while of those under medical treatment 11 per cent. died. . . . The percentage of cases ending in resolution was 36 per cent., which is practically the same previously found. Medical treatment should, therefore, be limited to a little more than a third of the cases." This, I repeat, is the opinion of a physician. The rate of mortality of Dr. Fitz's list is the same as that of mine; its rate of call for surgical aid even higher—two thirds as against one half. To his expression of opinion I add that of another physician, Professor Bridge,† of Chicago: "Surgery is imperative in cases of acute inflammation in the cæcal region with rather protracted high temperature that does not show positive evidence of subsidence within two days, or three or four days

* *Trans. of the Assoc. of Amer. Physicians*, 1890, p. 39.

† *Ibid.*, p. 34.

from the beginning." Dr. Fitz's brief summary of the indications for operating in the early stage is practically the same. He advises it for "urgent symptoms (rising pulse and temperature, increasing distention, and spreading pain), with or without a tumor."

This is about as much as any surgeon has advocated. We do not urge that a laparotomy should be done in every case as soon as the patient is seen, and we fully recognize the fact that an operation is a very different thing to the person at the other end of the knife—that the average patient would choose expectant treatment with greater risk rather than operative treatment with less risk. But if death or an ultimate resort to surgery is inevitable in from one half to two thirds of all cases, and if from the remaining one third or one half we exclude those in which improvement appears by the third day, the choice is more apparent than real; it is not whether the patient will submit to operation, but whether he will have it at once or later. And if the waiting carries the chance of a complication that may make interference hopeless; if the late operation itself shows a relatively enormous mortality (40 per cent. according to Fitz, 35 per cent. in my list); if, as Fitz states, recurrence is as frequent in those who undergo the late operation without removal of the appendix as in those who recover without operation; and if, as I fully believe, the risks in an early operation properly performed are small—can it be doubted that the early operation is the wiser choice?

By waiting a day or two at the very beginning to see if the attack may not subside spontaneously, some lives will undoubtedly be lost—some of those, for example, in which unprotected perforation takes place; but these are the exceptions, the possibilities, not the probabilities, and are to be classed with other exceptions, like those in which recovery takes place by spontaneous evacuation of an abscess through the bowel. Our action must be guided, not by the possible one, but by the probable nine or nineteen or ninety-nine. If the patient, with a full understanding of the matter, is unwilling to take even that risk, then I believe the surgeon is fully justified in operating immediately, exactly as he is justified in operating after an attack has ceased in order to prevent recurrence. But in such cases the decision should lie with the patient.

And in connection with recurrences, let me repeat that the experience contained in this list of cases indicates that the danger of a recurrent attack is greater than that of a first one, and that in such it is perhaps wiser not even to wait to see how the attack will turn, but to operate at once.

A word of caution as to the operation itself. In all I have said in favor of the early operation, I have had in mind its performance by those who are experienced in operating, with trained assistants, and with all possible care and precautions. While the recognition and removal of the appendix may in some cases be as simple and easy as any piece of abdominal surgery, it is much more likely to present serious difficulties and to call for the exercise of the soundest judgment and the most careful handling.

In the search for the appendix I have found it advantageous to follow the anterior longitudinal bundle of muscular fibers of the cæcum downward and inward; it ends at the root of the appendix. For the ligature of the appendix I have always used a catgut ligature, and have simply tied it about it as in tying an artery. No ill result has followed in any case, and I have seen no reason to abandon this simple method and resort to the more difficult one of turning in the cut end and suturing the opposed peritoneal surfaces. In some of my cases the latter method would have been quite impracticable, even if any confidence could have been felt that such suturing of the inflamed, softened, and sometimes suppurating peritonæum would have held.

Free packing with iodoform gauze has seemed to be of great service in arresting suppuration and preventing the spread of infection. I should be very loath to dress a suppurative case without it. I have used it not only in the immediate field of operation, but also and quite freely over and among the adjoining loops of intestine, removing it thence usually after forty-eight hours.

The external incision I have always closed in great part, bringing the drainage-tube and packing out near the lower angle; when the packing has been used more freely, among the adjoining loops of intestine. I have brought it out in two bundles, closing the incision between them. This partial closure of the wound has not interfered with drainage, and I have thought it made cicatrization more prompt and perhaps diminished the chance of hernia.

Finally, I may be permitted briefly to summarize the views held by those who have accepted the principles advanced by Dr. McBurney a year ago, so far as I may speak for them.

Inflammation in the cæcal region is, in the immense majority of cases, an inflammation in and about the appendix.

A certain proportion of cases will resolve spontaneously within two or three days.

The others, and they are much the larger number, seriously endanger life in their evolution and are liable at any moment to assume a condition that is practically fatal.

We have no means of distinguishing those cases which will go on to the formation of an abscess without accident from those in which this evolution will be gravely interrupted:

Early laparotomy—that is, laparotomy within the first three days—enables us to arrest the process by removal of the cause, and is less dangerous than expectant treatment.

It is maintained that such laparotomy should be done, not in every case, but only in those which clearly do not belong to the first mentioned, the resolving class.

54 East Thirty-third Street.

A New Method of producing Local Anæsthesia.—"Dr. Voituriez recommends in the *Moniteur thérapeutique* a method of producing local anæsthesia which certainly possesses the merit of simplicity. It is based upon the 'well-known anæsthetic properties of carbonic oxide,' and consists in pouring on the place to be anæsthetized the contents of two or three bottles of Seltzer water, preferably by means of the siphon which releases the water in a strong stream. The anæsthesia lasts five minutes and then gradually disappears. It is difficult to see how the 'well-known anæsthetic properties' of the oxide are exerted by external application. The effect, if any, is probably mechanical."—*Druggists' Circular and Chemical Gazette.*

NERVOUS AND MENTAL DISEASES OBSERVED IN COLORADO.*

By J. T. ESKRIDGE, M. D.,
DENVER, COL.,
FORMERLY POST-GRADUATE INSTRUCTOR IN NERVOUS DISEASES IN THE JEFFERSON MEDICAL COLLEGE AND PHYSICIAN TO THE HOSPITAL OF THE COLLEGE. ETC.

In a communication to the Philadelphia Neurological Society in September, 1887, I gave the results of three years' observation of the climate of Colorado on nervous and mental diseases, together with the views of several physicians in various portions of the State, practicing at altitudes varying from four thousand to ten thousand feet. In the present paper I can add three years' additional observations on the same subject. Two years of this time have been spent in Denver, where the field of observation has been much enlarged, owing to the size of the city and the hospital accommodations, which have enabled me to study cases from nearly every portion of the State.

In my former paper I stated that "among the inhabitants of Colorado we find more leisure in many places and a greater tendency to keep late hours and indulge in various dissipations than is common farther east. Many go to Colorado in search of health, and the separation from relatives and friends, added to the enforced idleness, is a source of worry and a certain amount of nervousness. Some go to better their fortunes, and, for these, investments in mines and various other uncertain speculations cause anxiety and unwonted excitement. Many who had lived quiet lives and kept regular hours for rest and eating in the Eastern States go to Colorado, overindulge in the use of alcohol and tobacco, and try their nervous systems by late and irregular hours. After allowing for all the modifying influences, exclusive of climate, I feel confident that by a careful comparison of certain nervous disturbances at sea-level with those of like nature met with in high and dry mountainous regions a difference will be found to exist; but the difference is much less than the exaggerated statements made by the laity here concerning the influence of Colorado climate on the nervous system would at first lead us to believe. That among the people of Colorado we have more of what is termed nervousness than exists in the same number of inhabitants at sea-level there can be no doubt, but consumptive invalids form a greater proportion of the population in Colorado than is found further east."

Most of the statements just quoted hold good to-day in certain portions of Colorado, especially in Colorado Springs, where I resided when the observations were made. In Denver, where I have made my observations during the past two years, there are less idleness and fewer consumptives in proportion to the population, but more business worry and bustle, and probably more irregular living, than in places like Colorado Springs and Manitou, where a greater proportion of the inhabitants have gone more for health than for business. If we take the people of Denver and compare them with a similar number in one of the wide-awake and business-going cities of the East, such as New York or Chicago, we shall find their habits and methods of doing business so nearly alike that but little difference in influence on the nervous system, except climatal, will be found to exist in Denver that is not active in the Eastern cities.

Most of my observations on the influence of Colorado climate on the nervous system have not been conducted by strictly scientific methods, but rather by comparing clinical observations made in Colorado with those made in Philadelphia, extending over a number of years. It must be borne in mind that conclusions reached by this method are distorted more or less by personal equation, the degree of inaccuracy depending largely upon the carefulness and faithfulness of the observer. A few facts, however, have been ascertained by strictly scientific procedure. While practicing in Philadelphia I devoted considerable time to surface-temperature observation, both in health and in disease. The number of observations amounted to several thousands, taken over various portions of the body. During the last four or five years I have continued these observations in Colorado, limiting the area mainly, but not exclusively, to the surface of the head. After allowing for changes in the mercurial thermometers, which time invariably effects, I find that the normal head temperature in Colorado is about half a degree (F.) higher than in Philadelphia.

I have also endeavored to compare the surface temperature of the body at various altitudes, but observations made at high altitudes, especially on Pike's Peak, owing to danger to my health in ascending high mountains, had to be intrusted to others, and I fear have but little value. No one unaccustomed to making surface temperature observations realizes the amount of care necessary to prevent inaccuracies. Time and time again I have requested my assistants to make such temperature observations for me, and I have repeated the observations a few minutes later and have gotten different results, the difference varying from a quarter of a degree to a degree.

Increased surface temperature in Colorado is what most clinical observers had inferred long before my observations, but the supposed condition, scientifically confirmed, becomes a fact and may help to explain many modifying influences the climate has on the functions of the organs of the body.

Mental Work.—I have often asked myself the question, and not infrequently propounded the query to others, whether a person is able to do more or less mental work in Colorado than at sea-level. The kind of mental work I refer to is hard study for several hours each day, continued over several weeks. The answer I have obtained from most persons whom I have interrogated on this subject is that they have not compared the effects and were undecided as to the results. I have tried to compare the effects on my own person, as I gave a few hours each day to hard mental work for many consecutive weeks in each year while practicing in Philadelphia, and much of the time since coming to Colorado, when my health would permit of it. I have devoted more or less time each day to mental work. I feel that the conclusions at which I have arrived from personal

* Read before the American Climatological Association at its annual meeting, held in Denver, September 2, 3, and 4, 1890.

experience may be open to objection. My physical power of endurance is much lessened since I contracted lung trouble, for which I came to Colorado, and, in consequence, mental effort sooner results in fatigue. I have found that three or four hours each day devoted to continuous mental work and extended over a period of a few weeks so weakens and prostrates me that I am compelled to give up all reading, except light literature, for a time. When I have felt fresh and have had a zest for study, I have thought I could accomplish more in a given time than I was able to do at a low altitude; but this is merely surmise on my part. The only persons who can approximate an accurate solution of this subject are those who, in good health, accustomed to do a regular amount of study East, have come to Colorado in the same state of health to pursue similar studies to those engaged in while East.

Sleep and Insomnia.—Under this heading in my former paper, the unanimous opinion of the physicians was that sleep was more easily obtained, more continuous, and more refreshing in Colorado than at sea-level. We have several classes in which to study the effects of the climate on the production of sleep, or as a cause of insomnia. Among these may be mentioned the tourist, including the business adventurer; the tired and overworked, both mentally and physically; and the health-seeker, especially the consumptive person.

On tourists or adventurers the effects are as varied as the temperaments of the individuals, and are modified by the habits and life of such persons while in Colorado. The restless ones among this class, who are never satisfied, but must have continuous excitement in scenery or some other diversion, rarely get good and refreshing sleep in Colorado unless tired out by physical exhaustion, when they run the risk of developing a temporary irritable heart, disturbances in digestion, and headache. Such persons frequently leave the State complaining bitterly of the evil effects of the climate on healthy individuals.

Those of this class who take things leisurely, more as a natural result of their temperaments than from the warnings of others who have been indiscreet, do not over-exercise, and allow themselves time for regular meals and rest, rarely fail to get prolonged and refreshing sleep.

About the only practical deductions to be derived from a study of the experiences of the tourists in Colorado are what to avoid in the invalid class.

The Overworked.—In this class are included the tired business and professional man, whose mental strain compels sedentary habits, neglect of proper exercise, and irregular hours for eating and sleeping, and the lady of family cares, as well as she whose vigor has been sapped by the unreasonable exactions of fashionable life. To these a visit to Colorado means, in the majority of cases, if too much physical exercise is not indulged in, prolonged and refreshing sleep. Such persons coming here from the East regain their strength rapidly; but we must not attribute all the good results to Colorado climate. Habits and modes of living for the time being are changed. The business man leaves worry and care behind; the professional man, relieved of the trials, annoyances, and anxious cares of his profession, seeks rest amid new scenes, while she who had been sore pressed with family cares and social obligations changes these for a quiet life. Much of the relief comes from "the change," irrespective of climate.

Having had an opportunity for a number of years, before coming to Colorado, of studying the effect of sea-shore resorts on this class of persons, I found a greater proportion unrelieved from insomnia than I find to be the case with those who seek rest and change among the mountains of Colorado, provided that a sufficiently quiet life is led here. According to the writer's experience, it is a rare exception for insomnia to continue in such persons after coming to Colorado, excluding a few cases of supposed active hyperæmia of the brain or irritable heart, reference to which will be made later.

Health-seekers.—I have found no reasons for changing the statements that I made three years ago: "That for the majority of persons, especially for the consumptive invalids, sleep is more easily obtained, more continuous, and more refreshing in Colorado than in the Eastern States. The tired, ill-nourished, and overworked person, who spent sleepless nights East, goes to Colorado and finds, as his nutrition improves, that sleep is prolonged and unusually refreshing. Cool nights throughout the summer season, as a rule, enable persons to get much more sleep and rest in Colorado than can be obtained at sea level during this portion of the year. Some, on going to Colorado, are unable to sleep well for a few nights, or perhaps weeks, while others get prolonged and refreshing sleep from the first. Those belonging to the latter group are much the more numerous. Those whose sleep is disturbed on first going to places of considerable altitude usually enjoy a sufficient amount of sleep for several months after they begin to rest well, but I doubt whether these are ever able to sleep as much as those who rest well on first going to high mountainous regions. There is a popular and almost universal belief among the laity, and physicians share this opinion, that one wears out the good effects of the climate after a few years' continuous residence in Colorado. I am firmly convinced, both from observations and from inquiries among those who have resided here a considerable length of time, that there is a great deal of truth in this prevailing opinion. Those who lead idle or sedentary lives are, I think, more liable to become sleepless after a considerable stay here than those who keep profitably employed in work that requires more or less exercise. Much severe mental work at high altitudes would be, I think, more likely to be followed by sleeplessness than the same done at sea-level. Tobacco, alcohol, tea, and coffee, if indulged in immoderately, apparently injuriously affect sleep more at high altitudes than the same indiscretions do at low elevations."

While the majority of persons who come to Colorado get refreshing sleep for a number of months, and in some instances for years, yet there are a few nervous, hysterical individuals who find great difficulty in getting refreshing sleep here. They are not able to sleep a sufficient number of hours, and the time for repose is frequently spent in broken sleep. Cases of insomnia in the East, due to active hyperæmia of the brain that is not relieved by rest, sleep

poorly, I think, in Colorado. At least this has been my experience with cases of the kind. Dr. Anderson, of Colorado Springs, and Dr. Sears, of Leadville, both say that cases of cerebral hyperæmia sleep well at each of the last-named places. I am inclined to believe that they have not distinguished, in their communications to me, between active and passive hyperæmia. I am led to believe, from observations, that cases of passive hyperæmia, or venous stasis of the brain, due to mental overwork, worry, loss of sleep, etc., are able to obtain abundant and refreshing sleep. I believe also that insomnia due to organic brain changes or active hyperæmia is made worse in Colorado. In my former paper I stated that "it is very difficult to say whether medium (4,000 to 6,000 feet) elevations, or the higher (7,000 to 11,000 feet), are the better for cases of insomnia." During the last three years I have known of a few persons who have come to the medium elevations, slept well for a time, then, becoming more or less sleepless, have gone to the higher altitudes, where they again slept well. I think such cases are rare. But, on the contrary, we frequently find that persons who become troubled with insomnia in the higher altitudes, where they had slept fairly well for a length of time, coming to the medium elevations of Colorado obtain refreshing and prolonged sleep. Pure air, good weather, and the amount of bright sunshine, even in winter, inviting persons to live outdoors a good portion of the time and take more exercise than they were accustomed to do East, are important agents in enabling one to get refreshing sleep in Colorado. What lessened atmospheric pressure has to do with inducing sleep, making it more profound, as some who reside in very high altitudes maintain, has yet to be determined. Those who have had experience with the pneumatic cabinet, and have noted the sensations experienced by their patients, may be able to enlighten us on this subject.

Irritable Nervous System, or Nervousness.—The opinions of the physicians of Colorado differ widely respecting the influence of the climate on a delicate and irritable nervous system, some believing the influence is great, and others that it is slight, if any exists.

An additional three years' experience with nervous affections found in Colorado enables me to emphasize what I said on this subject three years ago: "From what I have learned from observations and inquiry, I have no hesitation in saying that the inherent nervous temperaments—not those who are nervous from malnutrition, which the climate may and does remove in many instances—are made worse by a prolonged residence in Colorado. Further, I believe, and I think I am expressing the opinions of a number of physicians there, that many who are not usually considered nervous become so after a prolonged residence in Colorado." The nervousness may manifest itself by sleeplessness, irritable heart, with a tendency to passive congestion, especially of the gastro-intestinal mucous membrane, by a loss of appetite, failure of strength, lessened power of endurance, and considerable loss in body weight. Some suffer from restlessness and irritability of temper, and some complain of inability to concentrate the mind long on any subject. Persons thus affected and contemplating making their home in Colorado should not try to overcome their sensations by a prolonged and uninterrupted stay here, but they should try to spend a month or two each year at sea-level, which is almost invariably followed by an improved condition of the nervous symptoms.

Dr. Reed, of Colorado Springs, informed me that he had observed that child-bearing nervous women, after a prolonged stay in Colorado, recover less satisfactorily from the trying ordeals of the lying-in room after the birth of the second or third child than they had done after the first. The intensely bright sunshine, and the great amount of it, which is the boast of Coloradians, the dry atmosphere, and the winds, it seems to me, are factors in irritating an already irritable nervous system. Some have tried to lay the cause at the door of lessened atmospheric pressure. This may have something to do with it, but how much it is impossible to say.

Before beginning this paper I was informed that Dr. H. A. Lemen, who has practiced medicine in Colorado for a number of years and paid especial attention to diseases of women, would write on the influence of climate on women. I regret that his engagements have been such that he has been unable to contribute a paper on this subject. That the nervous system of woman is more irritable than that of man every one will admit, and that she in consequence suffers more from the irritating effects of our climate is self-evident. My note-book shows that a large percentage of those who suffer from the irritating effects of this climate is composed of women; but I will not go into details, hoping that Dr. Lemen, at some future time, will take up this subject and elaborate it.

Hysteria.—Three years ago I was able to give the results of the experience of various physicians with this protean disease as it occurs in the smaller towns in the State, and of my observations of it in Colorado Springs. My conclusions were then that it was of lighter form, shorter duration, and much less frequent in proportion to the population than observed in the large Eastern cities, but at the same time I endeavored to account for the infrequency from the habits of the people and their surroundings, and expressed an opinion that had we in Colorado all the conditions of a large Eastern city favorable for the development of hysteria, it would be found more frequent here than it is in cities at sea-level. Two years' experience in Denver, where conditions favoring the development and manifestation of the disease exist, convinces me that hysteria is not infrequent here, and that it is found in all forms, from the mildest to the severest. I have witnessed three cases in the male. From my present experience I am unable to say that the disease is of shorter duration and yields more readily to treatment than is found in the eastern portion of this country.

Chronic Alcoholism and the Opium Habit.—What must impress itself on every observer in Denver is the immense number suffering from the chronic effects of alcohol and opium. Other causes than climatal may account for this. A large proportion of those whom I have had an opportunity to interrogate on this subject admit having been addicted to the habit before coming to Colorado. Denver during the last few years has been the Mecca sought by

those broken down financially, and in this class alcoholism and the opium habit are common. Whether there is anything in the climate of Colorado tending to indulgence in alcohol and opium more than what is found at sea-level I am unable to say. Whether a larger proportion of the population here has begun the over-use of alcohol, or contracted the opium habit, in Colorado, than is found at sea-level, many years of carefully studied statistics must answer.

Chorea.—The physicians who favored me with their experiences with chorea three years ago were almost unanimous in their opinions that the disease is more frequent, severer, of longer duration, and less amenable to treatment in Colorado than at sea-level. I then expressed the opinion, from an experience with the disease in Colorado Springs, that it was unfavorably influenced by the climate.

Some of the physicians who were kind enough to answer my inquiries stated that they invariably sent all their cases of chorea to lower altitudes, with decided benefit to their patients.

During the past three years I have had the opportunity of treating and seeing in consultation numerous cases of chorea in Denver. So far, without a single exception, they have yielded to the ordinary treatment for this disease. Some cases have developed at low altitudes, and from force of circumstances have been brought to this city. These have yielded to treatment, but in one case the movements at first seemed to be exaggerated by the change to this altitude. My treatment has invariably been, in cases where the choreic movements were great, full doses of antipyrine or phenacetin until the movements had nearly ceased, when Fowler's solution of arsenic has been carried to the point of toleration, the dose reached in some cases being eighteen or twenty drops thrice daily. My former statements will have to be modified by saying that chorea at this altitude (about five thousand feet) seems to yield about as readily as at sea-level, and with no greater tendency to relapses.

Neuralgia.—A more extended experience convinces me that neuralgia is a much less troublesome and less frequent disease in Colorado than in low malarial districts. I have seen several cases of malarial neuralgia rapidly yield after coming to Colorado.

Migraine seems to be favorably modified on first coming to Colorado, but the attacks are not broken up, and, after a few months, the trouble returns and seems to be more persistent than it was at low altitudes.

In some of these sufferers, upon a return to a low altitude after they had spent some months in Colorado, long intervals with entire freedom from the disease have resulted.

Multiple Neuritis.—During the last six months I have seen six cases of this disease. So far I have been unable to discover any points of difference between the course, severity, and duration of the disease here and at low altitudes.

Epilepsy.—In my former communication the answers of the physicians in reply to my inquiries concerning the influence of the climate on epilepsy varied so greatly that no conclusion could be arrived at; some believed that the disease was unfavorably influenced by a resort to this climate, that it quite frequently originated here and proved rebellious to treatment; others thought it was uninfluenced by the climate, while some thought it was a very infrequent disease in Colorado.

I have had an opportunity of personally studying twenty-one cases of epilepsy since coming to Colorado. Sixteen of the twenty-one originated at low altitudes outside of Colorado, leaving five cases which began in some portion of the State. Of the Colorado group, the age at which the disease began was at the second, third, fourth, seventh, and thirtieth year, respectively. Of the imported cases, three began at the second, two at the fourth, six at the tenth, three at the sixteenth, one at the thirty-third, and one at the thirty-seventh year.

Causes.—Of the Colorado group, in one, injury to head from a fall; in one, hydrocephalus, and in three the cause is unknown. Of the imported cases, gastro-intestinal disturbances in infancy seemed to be the exciting cause in four, injury to head in five, and unknown in eight.

Sex.—Colorado group, three males, two females. Imported cases, there were fifteen males and one female.

Severe or Light Attacks.—In the Colorado cases three suffered only from the light or *petit mal*, and in two the *grand* and *petit mal* were found. In the imported cases all suffered from the severer manifestations of the disease, although a few also had occasional *petit-mal* attacks.

Time.—Of the Colorado cases, in one the seizures were limited to the waking hours, and in the other four they occurred both diurnally and nocturnally. Of the imported cases, in only one were the seizures of the diurnal character, and in the other fifteen the attacks occurred indifferently both day and night. So far I have not seen a case of epilepsy in Colorado in which the attacks were limited to the sleeping hours.*

Mental Effect.—Of the Colorado cases, there is decided mental failure in three, and in two the mind seems unaffected. Of the imported cases, insanity has developed in four and mental failure in ten, and in two the mind seems well preserved. In all of the Colorado cases treatment has seemed to be attended with the usual results found at low altitudes. The result of the climate on the sixteen imported patients is hard to determine. Two were excitable and unmanageable at times before coming to Colorado. These were soon decided to be insane after coming to this State, and one has since died in a condition of status epilepticus. On the fourteen others the climate had no appreciable effect. It will be observed that only one female epileptic is found among the sixteen coming from a distance to Colorado. This is accounted for from the fact that female epileptics rarely leave home. I have been unable to perceive that the climate of Colorado, especially at Denver, materially modifies the course of epilepsy, except, it may be, for a short time after the arrival of such patients here, when the disease is frequently benefited if the person keeps sufficiently quiet.

Insanity.—Since coming to Denver I find it even more

* Since this was written, a case of epilepsy with attacks only in the early morning hours (four or five o'clock) has come under my observation.

difficult to determine the influence of Colorado climate on the insane and in the causation of insanity than I did while practicing in Colorado Springs. Of the one hundred cases of insanity of which I have records of having seen during the past year in this city, about fifty per cent. were insane before coming to Colorado, and ten of the remaining fifty became insane in other portions of Colorado than Denver. During June of the present year I saw nine cases of insanity, six of which, so far as could be learned, developed in Colorado, but only four of these in Denver. From the 1st to the 19th of August I saw sixteen cases, only seven of which developed in Colorado. In July I saw six cases, three of which developed in Colorado and three outside the State.

This State has not as yet made adequate provision for the care of her insane, and some of the adjoining States and Territories are behind Colorado in caring for their insane, and, in consequence, there is a small insane nomadic population that travel from State to State and from city to city, as they can succeed in obtaining from county commissioners free transportation. As jury trials are expensive to adjudge persons of unsound mind insane, it sometimes happens that the cheapest way to get rid of such persons is to send them to an adjoining county or State.

Until Colorado succeeds in establishing ample accommodation for her insane, and until we can get the records of every case of insanity developing in the State and leaving it, it will be impossible to ascertain our insane population. It is evident that the proportion of our insane population in this State is rapidly increasing, but how fast statistics give us no idea.

Some patients with insanity, especially of the maniacal form, are benefited on being removed to a lower altitude. The number of cases of insanity developing in Colorado and taking a depressive form far outnumber those of an expansive nature. As yet there is no private asylum in the State where the insane with means to defray their own expenses can be cared for, and in consequence all such are sent to Eastern asylums.

Temporary Effects of High Altitudes.—Many go to the summit of high mountains and experience no inconvenience, while others at times can perform such feats with impunity, but at other times, depending probably upon the condition of their health, find mental or physical symptoms are produced thereby, and yet a third class is almost invariably inconvenienced by high altitudes. The following case reported in a former paper is to the point: "An intelligent young man, a tutor, in excellent health, started from Manitou early one morning in June, 1887, to go on horseback to the summit of Pike's Peak. The distance is about twelve miles. He had eaten a fair breakfast, but took no stimulants that day, either before or during the trip. He accomplished the ascent of the mountain in a few hours, in company with several others, and experienced no inconvenience. The party remained on the Peak about two hours before beginning the descent. Nothing peculiar was noticed in the young man until he had descended about two thousand feet, when some of the party observed his strange remarks and absent-minded condition. It was found on inquiry that he had forgotten nearly everything that had occurred during the day. When he reached Manitou, late in the afternoon, he did not remember at what hotel he had been stopping. He had paid for the hire of his horse, and his guide for his services, in the morning before starting, but on returning had forgotten all about it. When he reached his room in his hotel he had forgotten what he had done with his horse, and started to look for him. He remained in this confused and amnesic condition about thirty-six hours. I fortunately had an opportunity to interview him a few days after the strange occurrence. At the time of my conversation with him he said that he then remembered every incident of the day's journey, of which he was oblivious on the day of the ascent of the Peak. He told me he was not conscious at the time that anything was wrong with his memory, but was conscious of saying foolish things to which he could not help giving expression. He could afterward recall his dazed condition, loss of memory, and the laughter which he provoked among his party. He stated that he had on previous occasions ascended high mountains, some as high and some higher than Pike's Peak, but never before had had a similar experience from mountain climbing."

I have reported this case in full, as it illustrates a freak of memory found in a recent case of insanity which came under my experience. In July, 1887, a gentleman from Boston, member of a mountain climbing club, went to Estes Park, at an elevation of between 8,000 and 9,000 feet. At the end of a week or two he felt, as he expressed it, as though he were in a furnace, a sensation of intense heat, and began to lose flesh rapidly. In July of the present year (1890) I met an Englishman who had been in this country only a short time. He, in company with a number of gentlemen, was driving over some of the high ranges in the neighborhood of Leadville, at an altitude of 11,000 feet. He felt well and was quite hilarious, but suddenly became paretic in his legs and was unable to stand without assistance from a person on each side of him. He experienced no pain. The paresis disappeared as he reached a lower altitude, and he has had no difficulty in walking since. I have heard of one other who was mentally confused in making the ascent of high mountains in Colorado.

So far I have had nothing interesting to report from Professor Pickering, of the Astronomical Department of the Harvard University, owing to the fact that Pike's Peak was abandoned by him and his assistants after the first year (1887) as a point for observation.

Inflammatory Lesions of the Brain and Cord.—Under this division of my paper, read in 1887, before the Philadelphia Neurological Society, I gave the opinions of several physicians of Colorado in respect to the influence of the climate. Most of them thought inflammatory lesions of the brain and cord comparatively rare. Dr. Anderson, of Colorado Springs, stated: "The only lesion of the brain with which I have had any experience here has been softening, and I would say, from experience, that long residence in high altitudes is one of the most prolific sources of this affection. A number of cases in 'old timers' have come under my observation, and have proved fatal." Dr. Jacob Reed, Jr., of the same place, thought that he had

met with tubercular meningitis more frequently in Colorado Springs than he had in the same number of children either in Philadelphia or Michigan. So far as I know, only three cases of tubercular meningitis occurred in Colorado Springs from 1884 to 1887. The population during these years averaged about 6,000. I do not know the percentage of deaths from tubercular meningitis that occur in the Eastern towns the size of Colorado Springs. One death annually in a population of 6,000 seems to me comparatively small, and if we take into consideration the large proportion of the children of Colorado Springs born of consumptive parents, the death-rate is proportionately smaller to the consumptive population. It might be that the open-air life led by the children, and the bracing effects of the atmosphere, together with cool nights, even in midsummer, insuring refreshing sleep, enable the issue of consumptive parents to overcome the tendency to the development of the disease. Certainly this seems to be the case with reference to the development of tuberculosis of the lungs in children that are born and reside in Colorado. The dryness of the atmosphere favoring free perspiration is evidently a factor in the prevention of tuberculous and other inflammation of the central nervous system. My experience in Denver leads me to believe that tuberculous affections of the brain are proportionately larger here than in Colorado Springs. During my fourth year in Colorado Springs I saw two cases of infantile paralysis; none during the previous three years. I have observed only four such cases during two years in Denver. I did not hear of a single case of non-traumatic and non-tubercular meningitis during four years' residence in Colorado Springs, and have heard of only one during the past two years in Denver. I have studied six cases of acute myelitis—one of tumor of the cord, five of tumor of the brain, and eleven of chronic systemic degeneration of the cord—during the past two years in Denver, and have been unable to find any points of difference in the histories and progress between these troubles here and those of like nature observed at sea-level. Of their comparative frequency in this altitude I am unable to form an opinion, as most of the cases of gross lesions of the central nervous system observed here have been seen in hospitals in patients from various portions of the State. It is probable that persons suffering from chronic degenerative conditions of the cord experience an apparent improvement in their nervous conditions on coming to Colorado, not, I believe, from the direct influence of the climate on their nervous affections, but, indirectly, on account of improved condition resulting from the stimulating and bracing effects of the atmosphere. Dr. Solly thinks he has seen temporary good effects produced by a residence in Colorado on chronic inflammatory lesions of the cord.

Chronic Degeneration of the Brain.—That mental failure begins earlier in life in persons who have lived and struggled for many years in Colorado, and is in many cases attended by symptoms of chronic degeneration of the brain more frequently than is the case in similar individuals East, is recognized by the profession and laity generally. That this belief is correct, after six years' observation, I have no doubt. The practical question is, Is it due to long residence in high altitudes, as many maintain, or has it been caused by something peculiar, or at least prominent, in the lives and business habits of Colorado's pioneers? To answer this inquiry intelligently, we must consider several factors in the lives of these men. These persons lived in Colorado many years, surrounded by treacherous Indians and still more treacherous desperadoes. The mining interests of the State from 1859 to 1870 were her main and almost her sole resource for those seeking wealth. The uncertainty of fortune and the feverish excitement in the speculative miner's life—prospective millions to-day, realized poverty to-morrow—kept them under great mental strain. For some, to the prolonged mental excitement and worry we may add irregular hours for eating, often insufficient food and sleep for days, and no relaxation for years; and for others we may still add indulgences in alcoholic and venereal excesses; and still for a third class, gambling. Are not these causes sufficient to wear a man out at any altitude and in any climate? What is the cause of the early mental and physical wreck seen in so many of the Wall Street brokers and railroad magnates? Is it altitude? Certainly not. Then why attribute so much to high altitude as the factor determining the early break-down of persons who have crowded so much worry and mental excitement into so short a space of time? Again, some of the pioneers brought their wives to Colorado with them, and if altitude was the great cause of mental failure, these too should suffer in a similar manner. Practically this is not the case. The female often becomes nervous and sleepless, but she does not suffer in Colorado from chronic brain degeneration in the same proportion as the male sex. I fortunately have had opportunities to examine the brains and blood-vessels of some who have suffered and died in Colorado, comparatively early in life, from chronic brain degeneration. The blood-vessels have been found diseased in every case, and in some slight chronic meningitis has co-existed. I believe arteritis is the primary lesion in the majority of cases of early mental break-down in Colorado. The climate may, and doubtless does, play a small part in the matter, but not nearly so great as has been popularly attributed to it.

Apoplexy.—Three years ago Dr. Strickler, of Colorado Springs, with an experience of seventeen years there, and Dr. B. P. Anderson, with ten or twelve years' experience in the same place, stated that they had not seen a case of cerebral hæmorrhagic apoplexy in Colorado. This struck me as being very strange, and after referring to three cases of apoplexy that I had seen, or of which I had personal knowledge, occurring in Colorado Springs in 1887, I added: "I see no reason why hæmorrhagic apoplexy should not be as frequent in Colorado as we find it at sea-level." During the last eighteen months I have either had under my own care, or seen in consultation with other physicians, seventeen cases of apoplexy. I doubt if the climate has much to do *per se* in the production of apoplexy, but I do believe that violent exercise in high altitudes in persons with weak cerebral arteries is more dangerous than in such persons at low altitudes.

Sunstroke or heat stroke is almost unknown in Colorado. A few years ago it was said never to have been known to oc-

cur here. Its absence is accounted for by the active capillary circulation of the skin, by the free evaporation of moisture from the surface of the body, and by the increased amount of watery vapor given off from the pulmonary mucous membrane into the rarefied and dry air. During the summer of 1889 I saw a man who had been overcome and who died from the effects of the heat while working in the Grant Smelter of this city. The day was warm and sultry for Colorado. The man was working near one of the large furnaces in the smelter, and his death was due to artificial heat.

Paræsthesia.—Two cases of paræsthesia, one of which was seemingly due to high altitude, have recently come under my observation. After studying them more fully, if they should prove to be as interesting as they now seem, I intend to publish a detailed account of them.

CRUDE DRUGS COMPARED WITH CHEMICAL PRODUCTS.

By JOHN AULDE, M. D.,
PHILADELPHIA.

The lack of uniformity in galenical preparations has resulted in the development of two distinct classes of medical practitioners; on the one hand must be classed a large number who, knowing the unreliability of our medicaments, prescribe them indiscriminately, not to say recklessly, while others would have us believe that all remedial agents are for practical purposes worthless, sneering at any attempts made with a view to inaugurate a scientific basis for their employment. The former are not inaptly referred to as "plungers," and the latter have long been known as "therapeutic nihilists." It is quite possible that in time these two extremes of the medical army may be brought together through the exertions of those who occupy a position midway between the two factions. The solution of this problem, however, will most likely be attained by a compromise which shall have for a basis the employment of definite chemical products, and, with a view to advance the interests of the profession, I shall consider briefly some of the comparisons and contrasts connected with these two classes of preparations.

In conversation lately with a physician who had practiced for quite a number of years in the city of London, I was surprised to learn that until recently a majority of the physicians confined themselves to the use of tinctures, believing that they were far more reliable than fluid extracts. He assured me that many of the fluid extracts were practically inert in respect to distinct physiological activity, and that they were useful only in proportion to the alcohol they contained; these preparations, he said, could be taken in considerable quantity without other apparent effect than that which would naturally follow the ingestion of so much alcohol. Since the publication of my paper on Assayed Galenical Preparations, in this Journal (August 30, 1890), I have received a number of commendatory letters, and am therefore prompted to add some further reasons for the position I have taken. One gentleman writes as follows: "I have been trying to follow your advice in the administration of drugs to the letter, and in most cases have had phenomenal success, but occasionally I have failed to get the desired results; but, after reading your last paper in the Journal, I am led to think that my lack of success was possibly due to the administration of drugs that were not up to the standard, although I have tried to be very careful in that particular." Another practitioner writes me enthusiastically in regard to the wants of the physician in the direction of standardized galenicals, insisting that the physician as well as the patient suffer from this lack of uniformity. As an evidence of the dangers connected with our practice without the proper safeguards, he relates an incident which occurred in a hospital for the insane. It seems that the resident had been using the fluid extract of conium in teaspoonful doses to lessen the excitement and produce a calmative effect upon some of the inmates who failed to obtain needed repose. A new supply of the drug had been obtained, and the physician in charge was not aware that the product came from a different manufacturer, and, the usual dose being given, the following morning no less than seven patients were found dead. There could be no other conclusion than that these deaths were due to the greater activity of the new preparation which had been substituted for the old. With our knowledge of the physiological action of drugs, I doubt if such an accident could occur at the present day; our knowledge of the character and qualities of drugs is too thoroughly diffused, and the general intelligence which pervades all classes of medical practitioners forbids. If this were not the case, I should be inclined to believe that the regulation of these preparations was not an unmixed blessing.

The foregoing remarks will serve in a measure to indicate the principles which should govern us in the selection of galenical preparations; at the same time it will show that alkaloids, or their salts, which are true chemical products, might often be used with safety, and that they might be expected to supplant entirely the use of galenical products. It must be remembered, however, that the crude drugs have been used for a long time, and that by this usage we have become familiar with their physiological actions, statements which do not to any great extent apply to alkaloidal preparations. Again, many of these crude drugs contain alkaloidal substances, as well as resins and oils, which exercise more or less influence when taken into the economy, and consequently the same results can not be expected from the use of a single principle which has heretofore been obtained from the whole. It is a well-known fact, too, that alkaloidal substances in crude drugs often counteract the effects of one another; but I do not care to go into a discussion of that question at the present time. It will be sufficient to say that although the use of alkaloids is at present subsidiary to the employment of crude drugs, the true basis of medication rests upon this as a foundation, and in time I am convinced that, for the most part, the use of crude drugs will become subsidiary to the administration of the alkaloids and their salts.

Unfortunately, the method of determining the physiological activity and chemical value of galenical preparations

by assay process has been seriously opposed, although, strange to say, no one has made objections to the demands of experimental physiologists for reliable products as regards physiological activity for laboratory investigations. The necessity for integrity in laboratory products is freely admitted, but the same rule applied to medicaments to be used in the treatment of disease is regarded with disfavor. The exact effect of duly measured products upon dogs, rabbits, and guinea-pigs is esteemed of more importance than the saving of human life. Arguments have been advanced purporting to show that the variations are such that it would be impossible to accomplish anything which would further the interests of the practitioner by the methods proposed. This conclusion, it will be seen, throws the entire responsibility upon the physician, and compels him to adopt what is known among carpenters as the "try rule"; if the usual dose of the selected drug fails to produce the required effect, a larger quantity must be tried. The variations occurring in the alkaloidal purity of cinchona are cited to prove the unwisdom of attempting to govern finished products by the proportion of alkaloids. Thus, in the examination of a number of specimens of cinchona calisaya, Rusby finds that they vary from 2·2 per cent. total alkaloids to 5·1 per cent.; in cinchona red the variation was even greater, being as low as 5·2 per cent. and as high as 9·8 per cent. It will be seen at a glance that a drachm of one preparation would carry about four times the quantity of alkaloid found in the least rich of the crude drugs and the use of preparations of this class without some absolute knowledge of their supposed physiological powers would be exceedingly hazardous. Instead of being an argument against standardization, therefore, it proves beyond question the absolute necessity for the adoption of some such process as a guide for the practitioner.

An explanation will serve to show that the selection of cinchona as a basis for opposition to standardization was unfortunate, because these extraordinary differences occur in the products obtained from cultivated plants. The growers have discovered certain artificial means by which the alkaloid quinine can be greatly increased at the expense of the cinchouidine and other less desirable alkaloids, and this circumstance has been urged by the opponents of standardization, who would have us believe that the presence of a certain percentage of alkaloid is no true criterion of the value of the drug. It is alleged, for instance, that in the case of nux vomica the determination of the total amount of alkaloid would furnish no indication of the exact amount of strychnine contained. The sophistry of such argument is easily unraveled; if the presence of a larger or smaller amount of alkaloid does not modify the action of the drug, no further investigation is required. If the activity of the drug is increased or diminished in proportion to the total amount of alkaloid contained, the physician will learn to make due allowance for its presence, and will not be compelled to await the development of the characteristic physiological action when prescribing different preparations, or when administering it to different patients. How much better would it be were each product made to conform to certain tests as regards alkaloidal purity, thus relieving the physician from the peculiar and trying position as that in which he would be placed!

A distinction must be made between cultivated or domestic plants and natural plants—*i. e.*, those found growing wild. In deciding upon a preparation of digitalis, this is a most important matter. Professor Bartholow, in his lectures to students, has so regularly and persistently advised them to make sure that their patients obtain the English digitalis instead of the square packages put up by the Shakers, that his ideas on this topic have been disseminated all over the world. These are particulars which heretofore have not received much attention at the hands of practitioners, but doubtless in the future assayed galenicals are destined to occupy an important position in the armamentarium of the physician.

There are several other galenical products to which I should like to call attention, principally because of the variations which have been found in the crude drug, as I believe such knowledge should be as widely disseminated as possible. An examination of twenty-six specimens of belladonna root showed that the maximum alkaloidal strength of the different samples was about 50 per cent. greater than the minimum; that is, a single drop of the tincture or fluid extract made from one preparation would contain about two thirds of the alkaloidal strength of the other. The following are the exact figures: Minimum strength, 0·53 per cent. atropine; maximum strength, 0·74 per cent. total alkaloid. The examination of twenty-two specimens of belladonna leaves showed even a more decided variation, being 0·2 per cent. and 0·69 per cent., respectively.

An examination of ten specimens of colchicum seeds showed marked variations in alkaloidal strength, the percentage ranging from 0·4 per cent. to 1·06 per cent., or, in other words, one preparation was about two and a half times stronger than the other. Eight specimens of ipecac varied from 2 per cent. of emetine to 4·1 per cent., making one preparation twice the value in alkaloidal strength of that containing the minimum amount. Nine specimens of nux vomica varied from 1·1 per cent. of total alkaloid to 4·86 per cent., or we may estimate that the best preparation was about five times the value of the poorest. Fifteen specimens of stramonium leaves varied from 0·21 per cent. of alkaloid to 0·5 per cent.; or, to put it in another form, the best was two and a half times more active than the poorest sample. The foregoing memoranda have been extracted from a paper by Dr. Frank Woodbury (*Times and Register*), and are the actual records of the scientific department of Messrs. Parke, Davis, & Co., who have shown a commendable activity in bringing this question before the profession.

While it is true that the above includes but a small portion of the drugs in general use, and while it may be urged that a number of drugs, such as aconite, gelseminm, and hyoscyamus, can not practically be submitted to this test, owing to the very small proportion of the alkaloid and the expense connected with the operation, other methods which answer our purpose have been adopted and are found available. Thus aconite is submitted to the physiological test, gelseminm is subjected to certain manipulations with

Mayer's reagent, and a like method has been followed in the estimation of the qualities of hyoscyamus and other products.

In view of the extraordinary differences in alkaloidal strength of the crude drugs mentioned above, it seems a waste of words to argue the desirability of having some definite standard adopted which shall enable manufacturers to give us substantially the same product. The standard should not be so high that it would be difficult to conform to the requirements when the crop happened to be of an inferior quality; but, on the other hand, it should be fixed at a point that would insure the best results to the patient as viewed from the standpoint of the physician. At the same time, it would be necessary to make a distinction between certain kinds of crude drugs, just as is now made with reference to the different brands of cinchona, or to the two varieties of digitalis leaves mentioned. It seems incredible that any physician should object to the use of preparations which had been prepared under the supervision of thoroughly qualified chemists, who aim to afford him some positive information concerning the value of the drug he employs when studied from the chemical side. It is but reasonable to suppose that such preparations would be more acceptable to the intelligent physician than crude drugs prepared haphazard without any reference to their active principles, and which I have shown may vary all the way from a trifling percentage to 400 or 500 per cent. If it were a financial question, the percentages would very quickly receive attention.

1910 Arch Street.

Induction of Abortion for Uncontrollable Vomiting.—According to the *British Medical Journal*, "Dr. Pugliatti, of Novara, recommends that in cases of hyperemesis gravidarum where milder means have failed, abortion should be induced in the following manner: A bougie about two fifths of an inch thick is pushed upward to the extent of two inches into the uterus. After two or three hours this bougie is replaced by another slightly thicker, and after the same space of time a third, thicker than the second, is introduced. This last bougie is left in until distinct uterine contractions are set up. This method, according to Dr. Pugliatti, is free from danger. The membranes are not damaged, and in the worst cases there remains the great advantage that the lower uterine segment has been brought into a condition favorable for further proceedings."

Color of Beef Extract.—"It is not generally known that pure beef extract is of a dingy, unpleasant gray color, and that from its repulsive look, especially when dissolved or made into beef tea, it would, unless doctored up as is now done, have very little if any sale or use. Science and art come in nicely to remedy this defect by furnishing a harmless dye—namely, burnt sugar or caramel. This also improves the flavor as well as the appearance. We see no harm in this apparently nice little innocent deception—especially if druggists and physicians are fully acquainted with it, as they soon will be."—*Druggist's Circular and Chemical Gazette.*

Phenacetin in Typhoid Fever.—According to the *Lancet*, "Dr. Sommer has used phenacetin with great success in the treatment of typhoid fever, thus confirming the favorable views of its action which have been expressed by Masius and others. The dose employed for adults was four grains, which was repeated from two to four times during the twenty-four hours. Children were given only half this dose. No less than sixty cases were treated in this way, with but one fatal case, about which it is noted that the patient was not subjected to phenacetin treatment until three weeks from the commencement of the attack. In no case were there any serious complications."

NEW YORK, SATURDAY, OCTOBER 25, 1890.

RHACHIOTOMY FOR PARAPLEGIA.

In the July number of the *Annals of Surgery*, Dr. F. X. Dercum and Dr. J. William White report the result of a rhachiotomy on a German, aged fifty-five years, who was attacked in 1887 with severe burning and shooting pains in the shoulder and arms. Shortly after the development of these symptoms an increasing weakness of the lower extremities began that rapidly resulted in paraplegia, including the anal and vesical sphincters. Anæsthesia extended to the level of the nipple; trophic bed-sores developed; the deep and superficial reflexes became exaggerated; and percussion over the third, fourth, and fifth dorsal spinous processes caused pain, while percussion of the head in the direction of the spinal axis produced a severe girdle pain at the level of the nipples. The patient became worse during ten months of internal medication, so the first, second, third, fourth, and fifth dorsal spines and laminæ were removed, and the exposed thickened dura incised. The dura was attached to the pia by numerous adventitious bands that were broken down; nothing further was found about the spinal cord. A few hours after the operation the girdle pain passed off, the following day sensation in the feet returned, in two months voluntary motion was possible, and there was some control of the sphincters. In twelve months the patient had normal control of the sphincters and could walk about the ward, though his gait was a trifle spastic, and he had decided lordosis. The authors consider that more relief was afforded in this case than was explicable by relieving pressure, and they attach considerable importance to the rupture of the meningeal adhesions and the reaction of nutrition consequent upon the operation.

The authors are to be congratulated upon their success, that finds a parallel in a case reported by Mr. W. Arbuthnot Lane in the *Lancet* for July 5, 1890. A male, aged thirty-two years, noticed in 1888 a pain in the middle of the back while running; six months later a prominence appeared on the spine that was treated as a ganglion, but that soon developed into an angular curvature. About March 1st a weakness began in the right leg, and the toes caught a little in drawing the foot forward; soon (May 2d) there was complete paraplegia, with analgesia of the extremities, and the superficial and deep reflexes were markedly present. There was a sharp angular curvature at the tenth dorsal vertebra. On May 13th the spinous processes and laminæ of the ninth, tenth, and eleventh dorsal vertebræ were removed with a bone forceps, and a large mass of granulation tissue, resembling tubercular synovial membrane, was exposed in the canal. In the center of the neoplasm were about eighty minims of purulent material, that was let out in

removing the growth. A small portion of the latter extended forward to the right of the dura; the meninges were healthy. Power of motion of the extremities and diminution of the exaggerated reflexes rapidly ensued, and at the time of the report the patient could use his legs freely and with force.

The justifiability of surgical interference is demonstrated by the conditions found in these cases, that suggest the resort to operative measures in analogous conditions.

NORMAL PARTURITION COMPLICATED BY AN EXTRA-UTERINE TWIN FŒTUS.

Dr. Harriman, of Laconia, has reported to the State Medical Society of New Hampshire a case which he regards as one of twin pregnancy, with one fœtus intra-uterine and the other extra-uterine. From his account of the case, given in the *Boston Medical and Surgical Journal* for August 14th, it appears that the parturition of the intra-uterine child took place without much difficulty at full term. The patient was a primipara, aged thirty-two. The course of gestation had been marked by few unusual symptoms, except that at about the fourth month considerable pain was complained of in the abdomen; the last eight weeks were painful and locomotion was somewhat difficult. As seen at the time of confinement, the abdomen was greatly enlarged and unusually shaped; just above the pubes a rounded tumor or eminence presented itself, resembling a child's cranium, and lifting the integument and underlying parts to about the size of a man's hand. In the right lumbar region a second, smaller, eminence could be seen, about on a line with the umbilicus; while directly above the umbilicus, at the fundus, two smaller parts could be felt in close proximity. These various elevated or salient parts were believed to belong to the fœtuses of an ordinary case of twin pregnancy, rendered especially tangible by reason of an excessive thinning of the abdominal parietes. The duration of the labor was seven hours, and it resulted in the birth of a seven-pound living female infant, soon followed by its placenta and membranes. All pain ceased, but there was evidently another child, apparently fully grown, and it was in the abdomen. Strong pains were experienced on the day after delivery, and it was believed to be necessary to examine the patient under chloroform. Bimanual manipulation was made, and it showed not only that the uterus was entirely emptied, but that a fœtus presented with its head above the pubes, probably as large as the one expelled. The back of the child was against the abdomen of the mother, and the limbs, hands, and feet could be easily outlined through the thin intermediate tissues. No signs of life were at any time recognized in the abdominal fœtus. Pains recurred for several days after the effects of the anæsthetic had passed off, requiring large doses of opium to afford relief; but at the end of twelve days very little pain was complained of. With the exception of these pains, there were no untoward symptoms during the convalescence. The size of the ectopic tumor was gradually reduced, under purely expectant treatment, until, at the end of three months, it was not larger than a good-sized cocoanut. The patient had been well since delivery, and was ignorant of the nature of her still interesting condition. Seven months had elapsed since her confinement when the report of the case was made, as above stated, and there had been but little further diminution in the size of the tumor and no indication for surgical interference for the removal of the fœtus.

MINOR PARAGRAPHS.

EXTRAVAGANCE IN THE NAME OF CHARITY.

Dr. P. H. Kretzschmar, the presiding officer of the Board of Supervisors, at Brooklyn, has recently had occasion to write a very caustic veto touching a bill for repairs at the branch asylum for the insane at St. Johnland. The branch, also called the County Farm, is forty-two miles distant from the old asylum at Flatbush, and has proved an unexpectedly heavy burden on the taxpayers on account of "extras." It seems likely to cost the county only a trifle less than $2,000 per capita to simply house the pauper insane of that community, the cost of the land, chiefly farm lands and forests being included. There are costly stone-built and fully equipped hospitals in our cities that have cost not more than $2,000 per capita, cost of the land inclusive; while some others, less ornate but equally well adapted to their purposes, have been constructed for $1,000 a patient. From the standpoint of the medical superintendent, the effect of the political pilfering of the panper lunatic is deplorable. The medical men can not be ignorant that their patients are being defrauded, and yet their own mouths must be kept closed; that their "enthusiasm of humanity"—be it ever so bright and noble at the outset—is tarnished in an atmosphere of jobbery; and that their best efforts for the treatment and restoration of their unfortunate charges can not be put forth. Repression takes the place of encouragement and the sympathy of their superiors, and they fold themselves in a mantle of routineism.

If Dr. Kretzschmar has set before himself the task of defending the otherwise defenseless county lunatic, he has not entered public life in vain; therefore he should have the cordial support of his medical brethren.

MOUNTAIN DISEASE.

In the *Internationale klinische Rundschau* Dr. Liebig publishes an article in which he describes a disease peculiar to great altitudes. At an ascension of about 1,500 metres the first physiological change noticed was an acceleration of the respirations and dyspnœa; at a little greater elevation an unaccountable weakness of the legs came on, compelling the person to sit down. At a still greater height, from 3,000 to 5,000 metres, the veins would become full and the face livid, with headache, blindness, nausea, vomiting, bleeding from the various mucous membranes, and stupor. These symptoms seemed to have caused no organic changes, and usually disappeared in from ten to twelve days, only a slight dyspnœa, showing itself on exertion, and depression of spirits remaining. Various theories have been advanced from time to time as to the cause of these phenomena. The author accentuated the point that many of the cases of so-called mountain disease were also found in the low-lying lands of the heights, as well as at the great elevations with rarefied air; also that the disease was not constant, and that only under certain circumstances could the attack come on. If the rise was gradual and rest was taken at frequent intervals, the lungs could expand and the breathing adapt itself to the diminished air-pressure; but if the strength gave out,

then would follow a paroxysm. Again, if there was any lack of elasticity or constriction of the lung motor-power, the condition would be unfavorable for adaptation to the change in atmospheric pressure. The author was convinced, from extended experimental research and personal observation, that the disease was not due alone to the decrease of carbonic-acid gas in the air, nor to the diminished air-pressure, but to a peculiarity of lung elasticity which in some cases allowed the system to become surcharged with venous blood.

HYSTEROPEXY.

Dr. Pozzi proposes, in the *Annales de gynécologie*, a modification of hysterorrhaphy, which he denominates "hysteropexy," or binding of the uterus. The steps of the operation, after the uterus has been exposed and brought into close proximity to the abdominal wound, are the employment of a continuous silk suture passed from the left side of the patient to the right through the posterior sheath of the rectus muscle, the peritonæum, and the uterus in the middle line; thence the suture is passed outward through the peritonæum and the sheath of the rectus on the right side of the wound. The suture is thus passed three times through the uterus, transfixing the organ a short distance below the serous covering. The suture is tied and cut short. The more superficial layers of the abdominal wound are then brought together and closed by a separate suturing. Pozzi describes two cases of retroflexion of the uterus, with more or less of inflammatory adhesions, treated by this operation. The first case was entirely successful, and it was one in which Alexander's operation had been done without affording relief. The second case was less fortunate, having been attended by suppurative inflammation at the lower part of the wound, which was probably due to an imperfect boiling of the silk suture; but the uterus in both these cases remained firmly fixed to the anterior abdominal wall. Pozzi prefers the continuous to the interrupted suture, passed outside and through the integuments, as affording a firmer and more certain kind of adhesion.

HOW TO KEEP THE PAQUELIN CAUTERY IN GOOD ORDER.

According to *Le Praticien*, quoted in *L'Union médicale*, Paquelin's cautery would never be found out of order if the following instructions, given by M. Colin, were followed strictly: The benzin employed should be of from 700° to 720°, using the petroleum densimeter, at a temperature of 59° F., that is to say, it should weigh from 700 to 720 grammes to the litre. At most, it should not occupy more than a third of the capacity of the reservoir. In case of need, the hand-bulb may be replaced by a pair of bellows. During the whole operation, the temperature of the benzin should be kept at from 59° to 68° F., to accomplish which it is only necessary to hold the reservoir in the hand or carry it in one's pocket. Too high a temperature hinders the incandescence of the cautery. The platinum point should be placed in the lateral portion of the flame, at the level of the center. Use pure alcohol for the lamp. Avoid heating the platinum to the luminous point. If the cautery cools off, work the bulb vigorously, and if necessary place the point in the flame again. When the operation is finished, before allowing the cautery to become extinguished, bring it to a bright red by a few rapid insufflations, and then, while it is fully incandescent, detach the rubber tube from the handle suddenly. Let the cautery cool in the open air. Cleanse it with a moistened rag. If the instrument is not used very often, it is well to heat the various points from time to time.

ETHEREAL PREPARATIONS AS TOPICAL REMEDIES.

Sir James Sawyer, of the Queen's Hospital, Birmingham, writes in the *Lancet* in high commendation of ethereal tinctures as topical applications, chiefly on account of the osmotic capacity of ether and its solvent action on the fatty constituents of the sebaceous secretion of the skin, whereby the most intimate application of remedies to the epidermis is facilitated. He has made special use of ethereal preparations of belladonna, iodine, menthol, and capsicum.

THE CALIFORNIA VINTAGE COMPANY.

We have several times spoken in commendation of the wines and brandies furnished by the California Vintage Company. The company has devoted great care to the task of providing products of the best character for medical purposes, and has thus established a reputation in the medical profession that certain unscrupulous persons seem disposed to profit by, especially in the matter of tokay wine. The company announces that the trade name of its "Royal Tokay" has been copied, and that inferior wines sold under that name have, as might have been expected, proved disappointing to physicians who prescribed the genuine article. On that account, the company asks physicians to prescribe "Calvico Tokay" when they mean the wine heretofore known as "Royal Tokay."

A HOSPITAL CENSURED.

A coroner's jury in Kings County has passed a vote of censure against the Long Island College Hospital, in consequence of the death of a patient by suicide. The case was one of alcoholic delirium. The patient was confined in a private room, manacled by both hands and feet, and fastened to the bed with a rope, and yet she managed to slip away from her fastenings and cast herself down from the window, which was not barred. Under the terms of the jury's verdict "the authorities of the hospital are responsible for being negligent in not providing the proper care to prevent the said patient from taking her own life." Alcoholic delirium cases are not "interesting" ones at any hospital, as they entail extraordinary vigilance, care, and expense, but that is no reason why that class of cases should be overlooked or refused admittance, as is the manner of some who are in the receipt of municipal funds; while it may be a reason against an attempt to treat the sufferer at his home or in any private house. They are peculiarly hospital cases.

MALARIAL GERMS.

Dr. F. Neelsen, in the *Centralblatt für klinische Medicin*, quoting from the writings of Camillo Golgi, in the *Archivio per le scienze*, says that two distinct types of bacilli have been demonstrated as causing the tertian and quartan malarial fevers. Biologically, the tertian germ completes its development in two days and the quartan in three, and the amœboid movements of the tertian type are much more marked than those of the quartan. Clinically, the destruction of the hæmoglobin in the red corpuscles is much more rapid in the tertian than in the quartan. Morphologically, the difference is to be seen in the first stages of development; the amœba of the tertian has a more delicate mass of protoplasm and a sharper contour than those of the quartan, while the pigment granule and bacillus of the quartan are larger and coarser. Finally, segmentation takes place in a less regular manner in the tertian than in the quartan organism.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 21, 1890:

DISEASES.	Week ending Oct. 14.		Week ending Oct. 21.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	45	16	44	9
Scarlet fever	25	5	25	1
Cerebro-spinal meningitis	0	0	0	0
Measles	79	6	52	5
Diphtheria	46	15	57	17
Small-pox	0	0	1	0
Varicella	0	0	2	0

The District Medical Society of Central Illinois will hold its fifteenth semi-annual meeting in Decatur on Tuesday, the 28th inst., under the presidency of Dr. W. P. Buck, of Moawequa. The programme gives notice of the following reports and essays: Surgery, by Dr. G. N. Kreider, of Springfield; Some Notes on Hodgen's Splint, by Dr. W. J. Chenoweth, of Decatur; The Essential Oils in Surgery, by Dr. C. E. Black, of Jacksonville; Some Surgical Cases, by Dr. W. M. Harsha, of Chicago; Premature Expulsion of the Ovum, by Dr. L. P. Walbridge, of Decatur; Puerperal Eclampsia, by Dr. F. B. Haller, of Vandalia; Cervical Laceration, by Dr. L. A. Malone, of Jacksonville; Neurasthenia Fœminea, by Dr. Amos Sawyer, of Hillsboro; and Alcoholism and Insanity, by Dr. F. P. Norbury, of Jacksonville.

The Brooklyn Surgical Society.—At the meeting held on Thursday evening, the 16th inst., Dr. L. S. Pilcher read a paper on The Question of the Propriety of Suturing Recent Fracture of the Patella.

The United States Marine-Hospital Service.—A board of examiners will sit for the examination of candidates for admission into the service, at the Marine Hospital at Stapleton, Staten Island, N. Y., beginning on Monday, the 27th inst.

The New York Polyclinic.—Dr. Dillon Brown has been appointed instructor in intubation of the larynx on the cadaver.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 12 to October 18, 1890:*

By direction of the Acting Secretary of War, the retirement from active service on October 12, 1890, by operation of law, of Cherbonnier, Andrew V., Captain and Medical Storekeeper, under the provisions of the act of Congress approved June 30, 1882, is announced. Par. 11, S. O. 240, A. G. O., Washington, D. C., October 13, 1890.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending October 18, 1890:*

Bright, George A., Surgeon. Detached from temporary duty at the Naval Academy and placed on waiting orders.

Ayres, J. G., Surgeon. Detached from temporary duty at the Naval Academy and placed on waiting orders.

Lumsden, George P., Passed Assistant Surgeon. Detached from the U. S. Steamer Boston and granted three months' leave.

Anzal, E. W., Passed Assistant Surgeon. Detached from the Naval Academy and ordered to the U. S. Steamer Boston.

Smith, Howard, Surgeon. Ordered to appear before the retiring board at Mare Island, Cal.

Society Meetings for the Coming Week:

Monday, *October 27th:* Medical Society of the County of New York; Boston Society for Medical Improvement; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

Tuesday, *October 28th:* New York Academy of Medicine (Section in Laryngology and Rhinology); New York Dermatological Society (private); Buffalo Obstetrical Society (private); Medical Societies of the Counties of Queens (semi-annual—Garden City) and Rockland (semi-annual), N. Y.; Boston Society of Medical Sciences (private).

Wednesday, *October 29th:* Auburn, N. Y., City Medical Association; Berkshire, Mass. (Pittsfield) and Middlesex, Mass., North District (Lowell) Medical Societies; Gloucester, N. J., County Medical Society (quarterly).

Thursday, *October 30th:* Massachusetts Medical Benevolent Society (annual).

Friday, *October 31st:* New York Clinical Society (private).

Saturday, *November 1st:* Clinical Society of the New York Post-graduate Medical School and Hospital; Manhattan Medical and Surgical Society (private); Miller's River, Mass., Medical Society.

Proceedings of Societies.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Sixteenth Annual Meeting, held in Louisville, October 8, 9, and 10, 1890.

The President, Dr. J. M. Mathews, of Louisville, in the Chair.

Infectious Dyspepsia and its Rational Treatment by the Antiseptic Method was the title of a paper by Dr. Frank Woodbury, of Philadelphia, who limited his consideration of the subject to gastric dyspepsia. He considered dyspepsia entitled to recognition as a distinct disease. It was characterized clinically by manifestations of nervous disorder; so that Cullen had not been very far wrong in considering it as a neurosis, under the class of *Adynamiæ*. Its most marked symptoms were produced, the author believed, by the absorption of products of parasitic micro-organisms. Of late years bacteriology had made wonderful advance, and especially in the department of bacterial parasiticism, or infection, and its relation to disease. Abelous, a recent investigator of this subject, had found sixteen species existing normally in his own stomach, of which two were micrococci, thirteen were bacilli, and one was a vibrio. The presence of saprogenic microbes in the stomach, therefore, being constant and not incompatible with health, it became necessary to inquire why fermentation or putrefaction of the food did not occur after every meal. In other words, how was practical antisepsis obtained by natural processes? Three things were to be considered in this connection: (1) the food, (2) the digestive fluids, and (3) the physical conditions attending the act of digestion. Laborious, painful, and imperfect digestion occurring habitually, when not symptomatic of other disease, constituted dyspepsia; and when it was accompanied by fermentation of the contents of the stomach and general toxic symptoms, the result of microbian development, it might properly be called infectious dyspepsia. The disorder was sufficiently prevalent, and gave rise to enough discomfort and actual suffering in its victims, not only to deserve our serious consideration, but also to enlist our best therapeutic skill in their behalf. The excessive growth of micro-organisms during digestion was favored by slow movements of the stomach and by defective quantity or quality of the gastric juice. Acid dyspepsia, or sour stomach, might be due in rare cases to excessive secretion of hydrochloric acid, but was generally caused by lactic, acetic, or butyric fermentation, due to the presence of appropriate forms of bacteria in the stomach. The object of treatment of infectious dyspepsia was to prevent the excessive development of micro-organisms during digestion. This was sought to be accomplished (1) by the use of articles of diet that were not in a fermenting condition or readily fermentable; (2) by adopting such hygienic and tonic measures as would invigorate the bodily powers and especially bring the gastric juice up to its normal standard of quality and quantity, and increase the muscular power of

the stomach; and (3) by local antiseptic treatment, including the administration of drugs that retarded fermentation, and especially by irrigation of the stomach with weak disinfectant solutions or simply recently boiled water.

Help and Hindrance to Medical Progress.—Dr. JOHN H. HOLLISTER, of Chicago, read a paper on this subject. He said the possibility of progress was conditioned upon the present imperfection of attainment: results were dependent upon our abilities, upon our methods, and upon the obstacles to be overcome. The profession must command a much higher average of native talent; that talent must receive a much higher grade of culture; and the present methods of research on the part of the profession must be greatly modified and improved.

(*To be continued.*)

NEW YORK ACADEMY OF MEDICINE.

SECTION IN SURGERY.

Meeting of October 13, 1890.

Dr. B. F. CURTIS in the Chair.

Fractures of the Fibula.—Dr. A. J. MCCOSH showed a patient, aged forty-six years, who, on May 22, 1889, had been injured while in the act of lifting a horse's foot. The animal had rolled over against the inside of his thigh at the same time that his leg slipped under the horse into a position of extreme adduction, when he felt a pain and "something gave way" on the outer side of his knee, and he found himself unable to get up. On examination, the injury was found to consist of a breaking off of the upper end of the fibula, a fragment about three quarters of an inch in length being drawn upward for an inch by the contracting force of the outer hamstring. There was considerable swelling about the outer side of the joint, but no luxation could be produced. The limb was flexed in a double-inclined plane about thirty degrees and the thigh slightly bent on the pelvis. A strip of adhesive plaster steadied and pulled down the upper fragment. In this position the distance was about half an inch. At the end of three weeks a plaster-of-Paris splint was applied, the leg being semi-flexed. The patient went about on crutches, and at the end of the sixth week the splint was removed. After three months the patient walked without a limp and his injured limb was practically as good as ever.

A second patient was shown, aged thirty-one years, who had several years before sustained, on two occasions, a fracture of the left femur, and in consequence had had partial ankylosis of the knee joint. On August 26th, while descending some stairs, he slipped, and made a violent and sudden effort to recover himself. In doing so he heard and felt something snap on the outer side of his left knee. He fell and was unable to get up. Fracture of the upper end of the fibula was found. The upper fragment consisted of the styloid process, which was drawn slightly upward by the biceps tendon. The leg was flexed on the thigh and a right-angled splint applied, a pad pressing the upper fragment into place. The patient now had bony union.

Dr. C. A. POWERS said that of the record of four hundred and forty-eight cases of fracture of the leg in the service of Dr. W. T. Bull, at the Chambers Street and Bellevue Hospitals, there had been only one case of fracture of the fibula immediately below its head. No nerve lesion or paralysis had supervened, and perfect bony union had taken place in about eight weeks, with no limp and no deformity.

Extensive Bullet Wound of the Knee without Injury to the Bones.—The next case was that of a police officer. On the evening of August 21st he accidentally shot himself through the knee joint. The bullet entered the upper part of the joint, which it traversed for nearly its whole extent, lodging just beneath the skin. In its passage through the joint not the slightest damage was done to any of the bony structures. Blood and synovial fluid had oozed from the joint, and a few fragments of clothing were picked out. The joint was irrigated with borosalicylic solution and a small drainage-tube inserted, the upper part of the wound being packed with iodoform gauze. The knee was kept immobilized until September 23d. On September 26th, thirty-five days from the accident, the patient had begun to walk. It was now seven weeks and he walked without a limp. The leg could be flexed to a right angle and was daily improving. There was no doubt that in another month the patient would have a perfect limb.

Two Cases of Hip-joint Disease treated by Immobilization.—Dr. A. M. PHELPS showed two patients, one cured and the other under treatment by means of his immobilization splints. [A report of these cases to be published.]

His argument was that, if a case were treated in time and upon proper surgical principles, no deformity ought to result. It had been urged again and again, as an argument against fixation of the hip joint, that ankylosis was sure, or very likely, to ensue. The patient, a little girl, whom he now presented cured, had been put under treatment and her limb had been immobilized for sixteen months. It would be seen that she could now walk well, there was scarcely any shortening, and the joint was freely movable.

The CHAIRMAN said that the cases presented were speaking witnesses of the freedom from danger and excellent results that were attainable by the method.

Trendelenburg's Operating Chair.—Dr. WILLY MEYER described and showed a new operating table that he had brought from abroad. The table was designed by Professor Trendelenburg, chief of the surgical clinic at the University of Bonn, Germany, for the purpose of facilitating operations in the posture bearing his name. The only difficulty that had been connected with this position, which became especially evident in operations occurring in private practice, was the providing of a proper and steady support for the patient without the help of an additional nurse. Trendelenburg's new table overcame this insufficiency in a simple and effective manner, and offered besides many new and important advantages. The table consisted of four parts, which could be put together easily and taken apart just as simply. They were small enough to be sent by an express wagon to the patient's home. The four parts were: 1. The pedestal. 2. The seat, which had the shape of a carriage seat. 3. The rest for the back. 4. The rest for the head. Two movable shoulder hollows were attached to the back-rest. If everything was in place, the table could be adapted to Trendelenburg's posture by pressing down the handle at the top of the back-rest. The back-rest and seat were connected by hinges. The table could be lowered to 2¾ feet from the ground and raised to 5 feet by means of a rack and pinion, and also swung around a vertical axis. If one was operating with the help of light from the side, a full daylight view could always be got of the true pelvis and its contents without moving the whole table. There was a trap-door in the seat of the chair, by which means the whole perinæum, rectum, urethra, bladder, or vagina could be brought into view and fully exposed while the patient remained entirely undisturbed in the recumbent posture. The patient was put on the table, as in an ordinary office chair. The feet were secured by straps, and the shoulders caught by the hollows mentioned above. The table was now fastened, the patient upon it, at any height or angle of inclination. The table could also be utilized for office use by using a narrower seat and divergent foot-holders. There was no doubt that Trendelen-

burg's posture had been made much more useful by his new table, and would consequently be still more generally adopted. The chair could be obtained or ordered from Mr. F. A. Esthbaum, Bonn, Germany. The price without duty was about $90; with substitute seat. $125.

Lessons taught by Three Fatal Abdominal Operations.—Dr. J. B. Roberts, of Philadelphia, read a paper with this title. The operations were: 1. An attempt at nephrectomy, by the abdominal route, for tubercular and calculous nephritis. The autopsy in this case had shown quite clearly that lumbar nephrotomy would have led to a definite diagnosis, and possibly, perhaps probably, would have been followed by cure after a prolonged course of treatment. 2. Cholecystotomy. Gallstones were not found, and the cause of jaundice was not discovered. The post-mortem examination revealed a fœtid abscess between the gall-bladder and adherent coils of intestine, and indicated that the jaundice was due to pressure on the common bile duct by this abscess and other inflammatory products. 3. An operation for radical cure of a large umbilical hernia, in which death had followed. The clinical history of the first case was as follows: The patient, a woman aged forty-two years, had previously suffered with what was said to have been pneumonia, from which time she had never been in good health. About nine months previous to the writer's seeing her she had been seized suddenly with severe pain in the right side, which extended down into the right leg. This was followed by an illness which confined her to bed for fourteen weeks. During this time the urine was scanty and cloudy, and produced a burning sensation when being voided. Her health had progressively failed, and she had lost nearly fifty pounds in weight in the two years following the pneumonic trouble. Before she came under the writer's notice a tumor was discovered in the right hypochondriac region. Examination had shown the patient to be extremely emaciated, very feeble, and with a hard, globular mass, of about the size of a fœtal head at term, situated in the right hypochondrium. Counter-pressure on the loin caused the tumor to project much more prominently against the anterior wall. The urine contained large quantities of pus. The diagnosis was of a growth of renal origin, which, in all probability, would be found to be a disorganized and suppurating kidney, perhaps containing calculi. After consultation, an abdominal incision was decided upon, with the expectation of removing the tumor radically. An incision was made over the convexity of the tumor corresponding with the right semilunar line. The omentum, which was spread over and adherent to the mass, was torn through with the fingers. The presenting part of the growth consisted of a sac filled with a whitish fluid. This was recognized as a puriform collection in the kidney, and was then removed as well as possible, the contents being too thick to flow readily. About half of the tumor was separated from its surroundings, but it soon became apparent that it would be impossible to enucleate it completely, because of the firm adhesions to the viscera and the posterior abdominal wall. It was determined that the only safe course was to abandon the operation of nephrectomy and to stitch the peritonæum, at the edges of the abdominal incision, to the surface of the disorganized kidney. A portion of the tumor would thus be exposed, so that after its adhesion to the parietal peritonæum it would be possible to split open the diseased kidney and scrape away the disorganized tissue. The shock of such serious and prolonged manipulations, added to the patient's previously bad condition, had caused death within twenty-four hours. Removal of the kidney even after death was exceedingly difficult, because of its strong adhesion to the liver, diaphragm, intestines, and spinal column. When the specimen was cut open, a multitude of sacs was disclosed, with diffluent or cheesy pus for their contents. Within the kidney, calculous sand was discovered, and in one place a calculus as large as the tip of the finger was found. A large lumbar incision would undoubtedly have been better, for then the disorganized kidney could have been laid open and the pus and calculi removed by curetting, without involving the peritoneal cavity.

The second case was that of a woman, aged forty-two, who had suffered for sixteen years with periodical pains in the right hypochondrium. Nine months before coming under the notice of the writer her condition increased in severity, and a lump was noticed in the right side of the abdomen. The case was looked upon as being one of biliary calculi which could be treated by medicinal remedies. After a month's treatment an operation was decided upon, and the abdomen was opened over the gall-bladder, which was found greatly distended with liquid bile and bound by adhesions to the intestines. After evacuation of the bile, an incision was made into the gall-bladder and search made for calculi, but none could be found. The patient was in a fair condition after the operation, but died within twenty-four hours. The autopsy revealed a pus-pocket between the bladder and the transverse colon. The delay in attempting exploration was unfortunate. It was also possible that death might have been avoided even at the time of operation if force had been used and the gall-bladder separated from the adherent colon; this would, at any rate, have disclosed the pus, which was the chief cause of the serious symptoms.

The third fatal abdominal section of the series was in a woman, aged forty-six, who was subjected to an operation for the radical cure of an enormous umbilical hernia which, it was stated, had existed for four years. An incision only large enough to admit the finger into the sac was first made, with the hope that reduction of the mass might be accomplished by tearing up the adhesions and enlarging the umbilical opening. Adhesions, however, were so generally present that this was impossible. A large incision, therefore, was made so as to uncover the protruding intestine thoroughly. During the making of the incision some fœtid fluid escaped. The intestines were congested. Thick masses of inflammatory lymph were stripped from the sac wall and a good deal of congested and inflamed omentum cut away. In tearing through the adhesions between the various coils of bowel the two outer intestinal coats were torn at one place for about an inch, leaving nothing but mucous membrane remaining. The rent was at once sutured with catgut. The adhesions at the lower border of the ring were finally separated, but at the upper margin of the opening they were too firm to permit of separation of the protruding omentum from the abdominal wall. The ring was enlarged by incision, and reduction of the intestines accomplished, although a part of the colon and the stumps of the excised portions of omentum were left adherent to the upper border of the ring. A drain was not put into the peritoneal sac, but one was left in the umbilical opening. The patient's temperature after being put to bed was 101·2°; pulse, 104. The next day the abdomen became somewhat tympanitic, and the bowels were thoroughly moved with saline purgatives. Her condition becoming serious about forty hours after the operation, the abdomen was opened and thoroughly irrigated and drainage-tubes were inserted. Death had occurred in a few hours. It was evident from the autopsy that death had resulted from acute septic peritonitis, due to the introduction into the abdominal cavity of coils of intestine in a state of septic inflammation.

Dr. J. D. Bryant thought the reader of the paper had set an excellent example in recording his results so frankly. If all the unfortunate issues were so told, more would be learned than from the flowery recitation of successes. As to the kidney case, he thought it was a pretty well established fact that the re-

moval of this organ through the loin, if permissible at all, was better than through the anterior abdominal wall. Some believed that the surgical handling of the abdominal cavity, under proper precautions, offered no more danger than manipulation of other regions of the body. The speaker did not believe it proper to open this cavity when the object could be effected without doing so. The rate of mortality after removal of the kidney was about ten per cent. in favor of the lumbar incision. As to drainage of the abdominal cavity for the various requirements met with in the surgery of the region, he made it a rule to employ drainage when there was evidence to warrant the belief that inflammatory action would ensue at the site of the operation or in the tissues contignous to it. If there had been any exposure by the stripping off of the serous coat which could not be covered by drawing them together, he employed drainage by means of the tube or an iodoform tampon. The question of introducing into the abdominal cavity quantities of water or other fluid for the purposes of its better toilet had been a point of serious consideration. He should hesitate very much, where there was a local disease, or where an operation had been performed for disease which had not extended beyond the reach of the surgeon, to wash out the abdominal cavity, fearing that other parts might become infected. He should prefer to rely on local washing or the careful use of the sponge, followed by the introduction of a drainage-tube. As to the hernia case, he did not see how any other termination could have been expected, and thought that all had been done surgically that was possible.

Dr. G. M. Edebohls thought that Dr. Roberts had been quiet justified in opening the abdominal cavity. This in itself was not an improper measure for purposes of exploration. In case the growth sought for could not be removed by the abdominal route, or some other organ was found to be diseased, as in the case of a kidney, the cavity might be closed and the operation finished by means of a lumbar incision.

Dr. W. W. Van Arsdale referred to a method which was an exploratory incision, but one in which the abdominal cavity was not opened. All the tissues were divided down to the peritonæum, which was not disturbed. Most of the tumors usually sought for by opening the cavity could be diagnosticated readily without running this risk.

Dr. T. H. Manley thought the fatal results that so often followed these abdominal sections, from what was presumably septic invasion, could hardly be accounted for always in this way. In many of the cases there was scarcely sufficient interval for the development of general septic peritonitis. He thought that the element of shock was very often a potent factor in the fatal issue.

Reports on the Progress of Medicine.

DISEASES OF CHILDREN.

By FLOYD M. CRANDALL, M. D.

Points in the Pathology of the Paralyses occurring during the First Two Years of Life.—Henry Ashby (*British Medical Journal*, Feb. 8, 1890) divides the paralyses of infants into six classes:

1. Intra-uterine lesions (meningo-encephalitis). Grave lesions may occur in the fœtus, and it may continue to live and be born at term. The results of meningeal inflammation appear in the brains of idiotic children, which show atrophy, sclerosis, or chronic hydrocephalus.

2. Meningeal hæmorrhage. This occurs under a variety of circumstances during early life, but the invariable immediate cause is asphyxia, the delicate vessels being readily ruptured when distended with venous blood. The most common cause of asphyxia and resulting hæmorrhage is prolonged and difficult labor. It may also occur during paroxysms of whooping-cough, violent attacks of vomiting, or convulsions. The bleeding is usually bilateral, and most commonly involves the parietal region. The clot separates the pia mater from the surface of the convolutions, tearing the vessels which pass from the pia to the gray matter. The result is interference with the nutrition of the nerve-centers and more or less degeneration. In a majority of cases there are no symptoms of a surface lesion at first. An extensive hæmorrhage may be present without paresis or even convulsions. This is, no doubt, due to the undeveloped state of the cortical centers at birth. Symptoms appear as the child develops.

3. Syphilitic arteritis and softening. Disease of the brain in connection with hereditary syphilis is not common in young infants. When it does occur, it usually takes the form of an arteritis.

4. Acute cerebral paralysis. Much controversy has taken place with regard to the cause of this condition. It usually takes the form of hemiplegia, and may be due to tubercular meningitis, meningeal hæmorrhage, or embolism of the middle cerebral artery. The paralysis appears suddenly, convulsions or an acute febrile disease being present at the onset. The cause of the primary illness is often uncertain, and the relation of the convulsions to the paralysis, in most instances, can not be determined. This is also true of the hyperpyrexia which is frequently present. It has been suggested by Strümpell that a polio-encephalitis takes place analogous to anterior poliomyelitis. This is suggestive, but is as yet only a theory.

5. Acute spinal paralysis (atrophic paralysis, anterior poliomyelitis). Here the lesions are found chiefly in the anterior horns of the spinal cord, and are regarded by the author as inflammatory in character.

6. Peripheral paralyses. These play an unimportant part in the paralyses of early life. The group includes diphtheritic paralysis and the various paralyses resulting from injury to the nerves.

The Spinal Cord in Infantile Paralysis.—Angel Money (*Provincial Medical Journal*, Jan. 1, 1890) reports a case of great interest. The patient was a girl two years of age. Two months before, paralysis had been noticed following a brief illness marked by fever and vomiting, but no convulsions. This paralysis involved both lower extremities, which were wasted, flabby, and relaxed, but not rigid. The knee-jerk was lost on both sides, the abdominal and gluteal reflexes were absent, but the epigastric was easily obtained. The wasting was symmetrical. None of the paralyzed muscles acted to the strongest faradaic current, but all responded to the constant current of thirty cells. Six weeks after admission to the hospital the child died of pneumonia.

At the autopsy the diagnosis of pneumonia was confirmed. The parenchymatous organs were in a state of cloudy swelling. The brain and eyes were normal.

The spinal cord, on removal from its canal, presented no signs of disease, but, on making transverse sections, certain alterations were discovered in the lumbar region. In the middle of the lumbar enlargement a red area was seen to occupy each anterior cornu, that on the right side being the more extensive. Each anterior cornu had at its periphera a translucent border, which Dr. Turner has described. These changes existed in varying degrees throughout the lumbar enlargement. A microscopical section from the part where the disease was most marked showed (1) great distention and thrombosis of vessels, especially in the anterior cornu; (2) infiltration of the cornua, with abundant leucocytes; (3) absence of large multipolar or other nerve cells. The disease was not confined to the anterior horns, but spread in every direction, though the focus of mischief was certainly in the anterior horn. The lesion was most marked farthest from the center of circulation. The author believes that the morbid signs were those of acute inflammation.

As to ætiology, it is probable that a study of the circulation of the spinal cord may furnish an explanation. There is evidence for the belief that the gray matter is not as well supplied with blood as the white. In proof of this are the researches of Young and Ross, Adamkiewicz, and Moxon. The spinal cord is not well supplied with pabulum; the lower part is not as well supplied as the upper, while the gray matter and nerve nuclei have a most precarious supply. By invoking Cohnheim's theory of inflammation, the matter is easily explained. Upon any dam-

age to the walls of the blood-vessels, the phenomena of inflammation follow. Such injury may result from an abnormal condition of the blood or blood-pressure, and a direct result of this is damage to the vital protoplasm forming the vascular walls. If damage to the walls be sufficient, actual hæmorrhages occur, as found by Clifford Allbutt. The essential feature of this view is the unimportant part played by the nerve-cells in originating the disease. They are simply damaged by disorder of the blood-vessels, and are the victims of the vascular disease.

The Nature and Treatment of Rickets.—Dr. Kassowitz (*Wiener med. Wochenschrift*, Nos. 28 to 38, 1889) contends strongly against the opinion that rickets is due to a diminution of lime salts in the food or to their insufficient absorption due to weakened digestion. He believes the essential cause to be an inflammatory condition of the bony tissues and not a lack of calcareous material. After Wagner had demonstrated the specific action of phosphorus upon the bones of animals during the period of growth, the author conceived the idea of availing himself of the drug in the treatment of rickets. The favorable results first published in 1884 have since been confirmed by numerous observers. He usually administers the phosphorus in cod-liver oil, giving a half milligramme a day. This oil of phosphorus is, as a rule, well tolerated and may be continued during the warm season. When not well taken, the phosphorus may be exhibited in an emulsion of lipanine, mucilage, and syrup.

A Case of Myxœdematous Idiocy.—Bourneville (*Arch. de neurol.*, March, 1890) reports another well-marked case of this disease. Nothing unusual was observed until the child was three years of age, when development ceased and he began to grow fat. He first came under observation at the age of twenty-five. He was three feet in height: the anterior fontanelle was still open; the eyes were scarcely visible, due to swelling of the lids; the lips were thick and prominent; the cheeks fat and puffy. The thyreoid was absent; the neck was short and thick, and on each side there was a lipomatous mass, while similar masses existed on the sides of the trunk and in the axillæ. The abdomen was prominent and there was an umbilical hernia. The hands and feet were short and fat; the skin was waxy-white, and in places translucent. The speech was slow, the voice harsh, the vocabulary limited, and intelligence poorly developed.

The Pathology and Treatment of Tubercular Adenitis in Children.—Dr. Wohlgemuth (*Arch. für Kinderh.*, v and vi, 1890) considers this subject in a lengthy paper based on 127 cases. Of these, 46 patients were treated without operation, of which 24 per cent. completely recovered; 36 underwent a slight operation, and 63·9 per cent. recovered; in the remaining 45 the glands were completely removed, and 70·5 per cent. recovered.

The following conclusions are drawn: 1. In tuberculosis, during the first ten years of life the most frequent seat of disease is the glands, those of the neck being most commonly involved. 2. Adults are also attacked in like manner. 3. The prognosis varies according to circumstances more in children than in adults. 4. The greater the diffusion of involvement, the less favorable the prognosis. 5. Removal is less dangerous than has usually been alleged, but radical removal does not positively insure against recurrence, either local or general.

Two Cases of Congenital Malformation of the Heart.—Dr. Ludwig Klepstein (*Arch. für Kinderh.*, v and vi, 1890) discusses abnormities of the heart, and reports two cases. He considers ætiology under two heads: 1. Simple lack of development. 2. Inflammatory action. Endocarditis or myocarditis, occurring during the process of development, checks further growth; occurring after complete development, destruction of existing parts is the usual result. Anomalies of the larger vessels may occur as follows: 1. No division, the vessels forming one large tube. 2. Abnormal relative positions. 3. Unnatural size. 4. Combination of the last two—the most common anomaly.

In the author's first case the heart lay in a peculiar cavity, and was twisted upon itself like a root. The right ventricle was contracted, the walls of the left were much thickened, and there was no septum between the two. The foramen ovale was open. The pulmonary artery was large. It was an utterly useless organ.

In the second case the heart was large, the right ventricle was distended, the foramen ovale open. The left ventricle contained neither mitral nor aortic opening, nor vestige of the aortic valves. The aorta existed, but was small, while the pulmonary artery was abnormally large. The thymus was of unusual size.

Lithotrity in Children.—Southam (*Med. Chronicle*, June, 1890) believes that lithotrity is applicable in most cases in children when the stone does not exceed three quarters of an inch in its greatest diameter. In his experience, larger stones than this are rare, and, in a large proportion of cases, are capable of being crushed. The larger the stone and the younger the patient, the greater is the reason for performing suprapubic lithotomy in preference to the lateral operation.

Disease of the Heart as it occurs in children possesses many peculiar features, which are discussed by Dr. Mitchell Bruce (*Brit. Med. Jour.*, April 26, 1890) in an article of unusual interest. The various periods of this eventful disease may be considered under three heads:

1. Acute inflammation. Among the numerous causes, rheumatism is by far the most common, but is frequently "latent" and very difficult of detection. Far behind rheumatism are chorea, scarlet fever, diphtheria, measles, and tonsillitis. Even pericarditis is frequently of rheumatic origin, and the sooner this is recognized the better it will be for all concerned. Four tests may be employed to determine whether pericarditis be rheumatic or not: (1) The presence of an endocardial murmur; (2) the effect of antirrheumatic treatment; (3) the discovery, after minute examination, of tenderness of the joints; (4) the family history.

The symptoms of cardiac disease in children are mild and often very obscure; the physical signs are relatively distinct, but are marked by numerous peculiarities. The heart lies higher, the apex-beat being usually in the fourth space and more to the left than in the adult. The impulse, as a whole, is often widely visible and palpable. The sounds have a puerile character and are frequently divided, both periods of silence being marked. Reduplication is more frequent than in the adult. Prominence of the præcordia is especially striking, friction fremitus is distinct, and friction sounds are relatively loud. The area in the back over which systolic murmurs are conducted is frequently very extensive.

The immediate prognosis should be guarded. It is true that uncomplicated inflammation of the heart rarely proves directly fatal in young subjects, but its complications are frequently the cause of death. Rheumatic pleuro-pneumonia, associated with endocarditis and pericarditis, is a condition full of peril to life. The ultimate result depends largely upon the hygienic surroundings and social condition of the patient. It is, as a rule, better in the child than in the adult. It is unwise to give a too unfavorable prognosis, for in a certain number of cases the signs of valvular disease ultimately disappear.

Much may be done to prevent endocardial inflammation by immediately and vigorously combating every rheumatic process and insuring proper care. Salicine and quinine sometimes succeed where salicylates fail. Entire freedom from excitement, absolute rest in bed, and proper nursing must be continued week after week. Food should be given in small quantities and at short intervals, and must be rigidly fluid. The disease runs an irregular course, sometimes continuing for weeks. Such cases must be managed rather than "treated." Lack of firmness, patience, and consistency in management must too often account for the severity of some cases of chronic valvular disease.

2. The establishment and maintenance of compensation. There can be no doubt that compensation occurs with exceptional completeness and rapidity in the child. The first cause of interference with compensation is impoverished blood-supply, which may result from anæmia, starvation, dyspepsia, or disturbed action of the liver. The second set of causes rises in connection with muscular exertion. A weakened valve is sometimes strained by a child at play, but this is rare compared with the damage which often occurs to the heart of hard-working men. Nervous influences, which are so fruitful of evil in the adult, are much less active in the child. Yet a child suffering from cardiac disease should be guarded against nervous shocks, worry, and anxiety. The chief source of worry in most cases is the lessons and school. We must be on the outlook for symptoms of mental strain—headaches, night-talking, sleep-walking, or irritability of temper. At the same time we must see that muscular exercise is neither abused nor neglected. We should speak definitely as to games. Quiet cricket

may be allowed, but match games, with their excitement, and violent games, like foot-ball, must be totally forbidden. Cycling would seem to be a safe form of exercise, but actual experience proves it to be dangerous, from a tendency to over-ride.

The subject of chronic valvular disease must be specially protected from rheumatism. The most trifling symptom of its approach must not be disregarded. The most trying period is from the tenth year to puberty. The heart is then especially susceptible, and in most cases requires constant attention. Periodical examinations should be made, however free from symptoms the child may be. As to medicinal treatment, the routine employment of such drugs as digitalis and its allies is frequently unnecessary and often positively harmful.

3. Heart failure. Symptoms appear only when compensation begins to fail. In several important respects they are peculiar to the child. Pain is less prominent than in the adult, but dyspnœa is a constant and striking feature. Cardiac dropsy and albuminuria are infrequent. Epistaxis is not uncommon. Failure of compensation never arises without a cause. No attack of palpitation or dyspnœa should be allowed to pass without search for the cause, for upon that the prognosis will largely depend. If it be injudicious treatment, nervous strain, or muscular exertion, a period of rest and judicious treatment will restore the heart. The danger is much greater if rheumatism or other intercurrent disease is at work. On the whole, the prognosis of cardiac failure in the child is better than in the adult. When the more unusual symptoms, as dropsy and albuminuria, occur, the prognosis is especially bad, being worse than when those symptoms appear in the adult. Dyspnœa, palpitation, and failure of the pulse demand instant and active attention. Of the various new remedies and cardiac stimulants there are a number of much value, but, on the whole, digitalis, if rationally employed, is still the best. As prompt stimulants, ether, ammonia, and alcohol are familiar to all, but strychnine used hypodermically has in some instances an effect little short of marvelous in restoring the action of the ventricles. A one-per-cent. solution of the hydrochloride should be employed.

Mitral Stenosis in Children.—Dr. Sansom, in the *Lancet* of Dec. 28, 1889, reports forty cases of mitral stenosis with nineteen autopsies, all in children under twelve years of age. In the less marked cases a ring of granulations was found on the mitral aperture on its auricular aspect. They are in some cases friable and fibrin-covered, in others fibrous and firmly fixed. The subjacent structures were more or less thickened. In the more pronounced forms the mitral curtains were fused to form a funnel. The button-hole opening, so common in adults, occurred in children in the proportion of but 1 to 8 as compared with the funnel-shaped opening. The left ventricle was usually of normal size; the right chambers were almost invariably dilated. Mitral stenosis was in no case congenital. It was extremely rare under five years, and was invariably the result of endocarditis. As to ætiology, rheumatism was the most common factor. In the more severe forms of rheumatism mitral insufficiency was far more common than stenosis, while in the milder forms the proportion of the latter greatly increased. The author believes that stenosis is the result of a limited and slow endocarditis, while insufficiency is due to retraction of the valves, the result of more intense inflammation.

Strophanthus in Cardiac Disease in Children. — Dr. Moncorvo (*L'Union médicale*, Jan. 9, 1890) has employed strophanthus extensively in children from fifteen months to fifteen years. He has seen no intolerance manifested to the drug even in the youngest cases. It strengthens the muscular force of the heart and frequently regulates the rhythm without prejudice to arterial tension. He reports eight cases of mitral disease with irregular rhythm and the symptoms common to cardiac disease in young children: palpitation, dyspnœa, insomnia, and precordial oppression. The symptoms were invariably relieved, sometimes immediately, and ultimately disappeared more or less completely. In some cases of an asthmatic type the irregular heart's action was improved without relief to the dyspnœa. In other cases the dyspnœa was made to disappear. In three cases of nephritis with lesions of the heart, œdema disappeared under the use of the drug, and the action of the heart was improved. In broncho-pneumonia and other pulmonary diseases complicated by dyspnœa and weakness of the heart, strophanthus rendered excellent service.

In most instances the good effects persisted after the administration was suspended. The temperature was not reduced nor was any effect noted on the nervous system.

Lipanine as a Substitute for Cod-liver Oil.—Galatti (*Arch. f. Kinderhk.*, xi, Fas. 1) reports twenty-seven cases of tuberculosis and rickets treated by this preparation with very favorable results. It was well tolerated and taken without difficulty. Although the appetite improved in all cases and there was a surprising increase in weight, the progress of the disease in tuberculous cases was unchecked. The dose is a dessertspoonful, pure or combined with syrup.

[Lipanine is an artificial compound of oil and a fatty acid. Mering uses a mixture of 100 parts of oleic acid with 6 of olive-oil.]

The Causes of Laryngismus in Infants.—Mantle (*Brit. Med. Jour.*, Feb. 8, 1890) describes a form of laryngismus characterized less by stridulous breathing than by a distinct catch in the breath, bringing respiration temporarily to a standstill. The infant is observed to awake suddenly from sleep and struggle for breath. He seems to be suffocating, but eventually recovers the breath. Sometimes there is a crowing inspiration, but frequently disturbance of the natural rhythm of respiration is the only symptom noticed. At first spasm is confined to the laryngeal muscles; but if the disease continues, other muscles are at length involved. Carpo-pedal contractions soon appear, and these may be succeeded by general eclampsia. In the words of Dr. Cheadle, "Laryngismus, tetany, and general convulsions are the positive, comparative, and superlative of the convulsive state in children."

Among the causes of this disorder, rickets is by far the most common. The best explanation for this would seem to be that the weakened and deformed chest wall of the rickety child interferes with the proper aeration of the blood. Increased venosity without doubt tends to irritation of the respiratory centers. Another cause described by Goodhart is excessive recurving of the epiglottis in its vertical axis, as if it had been bent in half down the middle, and that thus the ary-epiglottic folds are brought into apposition, and a mere chink is left between them. In cases of this character the symptoms gradually disappear, but are little relieved by treatment. Another cause is found in enlarged bronchial glands, but this accounts for but few cases. Enlargement of the thymus gland accounts for a still smaller number.

There is still another cause which has not before been recognized, except indirectly by Ringer. This is elongation of the uvula with thickening and congestion of the palatal folds. The history of an extremely interesting case is given in detail. A child, eight weeks old, suffered successively from laryngismus, carpo-pedal contractions, and general convulsions. Removal of the uvula, which was much elongated and congested, resulted at once in complete and permanent cure.

Congenital Laryngeal Stridor.—Dr. Suckling (*Lancet*, March 15, 1890) reports the case of an infant, one week old, suffering from laryngeal stridor. It had existed since birth and was persistent, though worse at times, especially during sleep. There was no evidence of syphilis. The stridor was attributed to some congenital abnormity in the larynx, possibly a recurved epiglottis. Such cases are unaffected by treatment, and the stridor gradually disappears.

Diphtheria and Croup.—It is believed quite generally in Germany that there is a simple idiopathic or inflammatory croup, less frequent than diphtheritic croup, but often so grave as to require tracheotomy. Goldschmidt (*Ctrlbl. f. klin. Med.*, No. 48, 1889) is inclined to doubt the existence of simple idiopathic croup. Though such a disease may occur, it is in most cases a manifestation of diphtheria. This is proved by the contagious character it often presents, by subsequent paralysis, and by the small membranous spots so frequently found upon autopsy. In these cases the results of tracheotomy are especially good, as they are rarely complicated.

Recent Investigations in Diphtheria.—The *Canada Medical Record* (May, 1890) reports the investigations of several government inspectors into the origin of certain outbreaks of diphtheria. The most interesting points are presented in parts of the report which deal with the influence of factories in disseminating the disease and the possibility of conveyance of the infection by clothing. Evidence is undoubted that factory women employed during the week in a town where diphtheria was prevailing communicated the disease extensively in villages where they spent Sun-

day. Instances are given of the families of clergymen and doctors in rural parts owing their attacks to the head of the family bringing the infection home in the clothes. It was also carried by coats and straw plaits sent out from infected houses. The potent influence of schools in disseminating and furthering the disease is proved beyond a doubt.

A Case of Chorea of unusual severity is reported by Dr. Henry Ashby in the *Medical Chronicle* for May, 1890. The patient was a girl, nine years of age. Choreic movements began early in June. On the 19th the power of speech was lost, a condition which lasted eighty-one days. At about the same time control over the limbs was lost and marked paralysis soon developed. Several joints also became tender and the choreic movements were greatly increased. Early in July a mitral regurgitant murmur developed, the rheumatic pains were constant, and subcutaneous nodules began to appear. At one time at least two hundred were present, being situated on the scalp, borders of the scapula, along the ribs, and in the tendons of the hands and feet. On the 12th of July a friction sound was heard over the heart, followed by a large effusion into the pericardium. This disappeared, to be followed by another attack in August. In August, emaciation and exhaustion were extreme and the paralysis marked. Gradual improvement then began to be noted, which continued till January. Heart failure then set in, accompanied by anæmia, dyspnœa, and œdema, and the patient died February 19th. The case illustrates in a remarkable manner the close association between chorea and the rheumatic state. The loss of speech was doubtless due to a loss of control over the muscles of the tongue and lips.

The Transmission of Aphthous Disease to Infants.—Weissenberg (*Allgem. med. Central-Zeit.*, No. 1, 1890) reports a case of aphthous stomatitis in which the cause could be clearly traced to tainted milk. It is probable that an epidemic of this disease in Berlin was due to diseased animals. It was not simple stomatitis marked by a shallow round ulcer, but true vesicles occurred, which dried and disappeared without leaving a cicatrix. Contagion may result from direct contact, or through the milk of infected animals. The disease was produced even when one part of the infected milk was mixed with eight parts of sound milk. Sibberty isolated a micrococcus from the milk of the diseased cows, but reached no positive conclusion.

Insomnia in Infants.—Dr. Jules Simon (*Revue mens. des mal. de l'enfance*, March, 1890) considers insomnia a symptom of much importance in infants. In many diseases it is a symptom of minor importance and of no special interest. In others it is one of the chief manifestations of the disease. The influence of dentition has been greatly exaggerated. Unless congestion of the gums or surrounding parts is present, it causes but little disturbance of the sleep.

Dyspepsia and indigestion are the most common and universal cause of disturbed sleep, even without the definite symptoms of vomiting, diarrhœa, or marked constipation. A discussion of the treatment would involve a review of the whole subject of dietetics.

Causes referable to the nervous system probably occur next in frequency. All young infants may, even in the first year, present evidences of acute cerebral congestion. Extremes of either cold or heat may produce the same result. A child who has been exposed to a strong wind during its daily airing, or one who has had insufficient protection from the sun, may pass a restless and uncomfortable night. This condition must be distinguished from the insomnia of meningitis, which, in some cases, is for many days the only sign.

In older children, headache due to overtaxing of the brain is not uncommon. Anæmia and rapid growth, in conjunction with over-study, is a fruitful cause of insomnia. In children of rheumatic parents this tendency is especially marked. Among nervous causes in these older children, hysteria, chorea, and epilepsy are the most common. The young hysterical subject is always liable to insomnia, with or without headache. Some attribute all headaches of this period to hysteria, but the author believes that the distinction should be carefully made between such headaches and those due simply to rapid growth and over-study.

The insomnia of epilepsy is peculiar to itself, and is sometimes the only symptom for a considerable period. The child suddenly wakes from profound sleep, sits up, and begins to cry, but soon lies back, as if exhausted, and falls into a deep sleep. These attacks are always accompanied by incontinence of urine. Insomnia complicating chorea is an exceedingly grave symptom.

Earache is always accompanied by insomnia, and usually by continuous crying. Hernia is a cause of pain and sleeplessness that is frequently overlooked. Intermittent fever is in some cases marked by wakefulness at a definitely recurring period. Insomnia and headache are prominent and early symptoms of albuminuria. Disturbed sleep is frequent in children of six or seven years of the rheumatic diathesis, and is accompanied by profuse sweating and severe headache.

New Inventions, etc.

A RETINOSCOPE AND STRABISMOMETER COMBINED.

By John Herbert Claiborne, M. D.

The instrument represented by the following cut consists of a plane mirror an inch and three quarters in diameter, perforated centrally by an aperture for the eye. As a handle to the mirror a strabismometer has been employed. The handle is attached by a joint which snaps and holds fast when extended. Its length is such that when flexed over the mirror it exactly spans it and, being slightly arched in the center, protects the glass from fracture. As may be seen, the handle at its broad extremity is crescentic in shape, and is marked off in lines. The width of the scale is an inch and two eighths, so that a deviation of five eighths of an inch in the visual axis may be measured.

The instrument is handy and may be carried with comfort and safety in the waistcoat pocket. It is of value in the diagnosis at a distance of errors of refraction and in the estimation of the amount of strabismus. It is made by Messrs. Schmidt & Berlin, 16 East Forty-second Street.

A NEW ADJUSTER FOR APPROXIMATING AND INVERTING THE EDGES OF WOUNDS, ESPECIALLY IN OPERATIONS ON THE CERVIX UTERI.

By Sinclair Tousey, A. M., M. D.,
HOUSE SURGEON TO THE ROOSEVELT HOSPITAL.

The instrument that I have devised (that has been in successful use in the Gynæcological Division of this hospital) is seven inches long (of just twice the size of the illustration), and is in effect a miniature pitch-

fork. The points are as sharp as those of an ordinary tenaculum, and the notch between them is a little less than an eighth of an inch in breadth and depth.

Puncturing the edge of the wound, it can be accurately adjusted and inverted as required while the sutures are tightened. In most operations upon the cervix, especially in Schroeder's and Emmet's operations, the adjustment is much more readily accomplished than by the ordinary tenaculum.

Mr. Clarence Ford has carried out my idea in the construction of an instrument of a single piece of polished steel, which can be readily kept aseptic.

Miscellany.

The Evils of Early Marriage in India are thus spoken of editorially in the September number of the *Indian Medical Gazette*, of Calcutta:

The case of fatal rupture of the vagina in a child-wife consequent on sexual intercourse with a mature husband which we reported in our last issue has attracted attention to a subject of very great social importance—namely, the nubile age of females in this country. The appearance of menstruation is held by the great majority of natives of India to be evidence and proof of marriageability, but among the Hindu community it is considered disgraceful that a girl should remain unmarried until this function is established. The consequence is that girls are married at the age of nine or ten years, but it is understood or professed that the consummation of the marriage is delayed until after the first menstrual period. There is, however, too much reason to believe that the earlier ceremony is very frequently, perhaps commonly, taken to warrant resort to sexual intercourse before the menstrual flux has occurred. This came out clearly at the recent trial, and was indeed advanced in extenuation of the prisoner's "rash and negligent act" by his counsel, and from evidence which we have gathered since the trial it may be accepted as true that pre-menstrual copulation is largely practiced under the cover of marriage in this country.

From this practice it results that girls become mothers at the earliest possible period of their lives. A native medical witness testified that in about 20 per cent. of marriages, children were borne by wives of from twelve to thirteen years of age. The state of matters thus revealed implies consequences of a very hurtful nature to the victims of the practice of immature sexual congress, to the welfare of the race, and to the tone and well-being of society in general. As regards the unfortunate children, apart from the demoralization entailed by premature sexual intercourse and the evils consequent on the assumption of the functions of womanhood in childhood, there is abundant evidence to show that pain, damage, and death result from premature copulation. Cases of death caused by the first act of sexual intercourse are by no means rare. They are naturally concealed, but ever and anon they come to light. Dr. Chevers mentions some fourteen cases of this sort in the last edition of his *Hand-book of Medical Jurisprudence for India*, and Dr. Harvey found five in the medico-legal returns submitted by the Civil Surgeons of the Bengal Presidency during the years 1870–'72. But very serious injuries may be inflicted by a mature male in intercourse with an immature female short of being fatal—lacerations of the external genitals and severe tearing of the vaginal canal. These are inevitable under the circumstances in every case in which mechanical measures have not been previously resorted to for dilating the sexual passage. There is reason to believe that such measures are not infrequently used, and it is difficult to decide which is the greatest evil and disgrace—the injury caused by the natural method, or the degradation due to the artificial. But more physical injury and mortality are probably due to premature maternity than to premature copulation. The function of parturition demands a higher degree of maturity of the skeleton and soft parts than the function of copulation. Difficult and delayed labor, laceration and sloughing of the passages, death of the child, exhaustion, fever, abscesses, contractions, and fistulæ are the principal consequences of premature maternity, and all of these are more common than is generally known. Then early maternity causes premature aging, and accordingly the women of this country lose the bloom of youth and vigor of adult life long before they ought or would if they were allowed to mature before becoming wives and mothers. Menstruation is not a sign of maturity. It is in the great majority of cases a sign of puberty—of ovulation and impregnability. It is not even an infallible sign of that. Some female children menstruate long before they begin to ovulate, others menstruate once casually and the regular establishment of the function is delayed for many months; in others ovulation commences long before menstruation appears. Recent researches tend to show that menstruation and ovulation are by no means so closely related as they were supposed to be, and menstruation is not therefore the certain and infallible sign of marriageability it is supposed to be in India. But maturity—physical, mental, and moral—is not attained in women for many years after menstruation has appeared, and it is true beyond question or doubt that maternity as a function and duty should be undertaken by mature women and not by immature girls. As regards the race, there can be equally little doubt that the marriage of children, often with aged males, tends to the physical deterioration of the human stock, and physical deterioration implies effeminacy, mental imperfection, and moral debility. The effect of premature covering and bearing is very well understood in stock-breeding, and the more robust races of the world contract and consummate marriage after and not before maturity in every sense of the term has been reached by both man and woman. The social evils caused by infant marriage are a theme rather for the moralist than the physician, but they are very evident, more especially in connection with rape and prostitution. Social customs find in vice and crime hideous exaggerations, and the legalized love of child-wives in marriage is apt to be represented by lust for female children outside of marriage.

The medico-legal returns submitted to the Inspector-General of Hospitals by the Civil Surgeons in the Bengal Presidency for the year 1868 and 1869 formed the subject of a report prepared by Dr. K. McLeod, and those for the years 1870–'71 and 1872 by Dr. R. Harvey. Dr. McLeod's report includes forty-eight cases of rape. In two the age is put down as five years, in seventeen between six and ten, in ten between eleven and fifteen, in seven between sixteen and twenty, in three above twenty, and in nine the age was not stated—that is to say, about half of the victims were under ten and about three fourths of them under fifteen. Most of these children had been badly hurt, some had venereal disease, and in some "the parts gave evidence of habitual or repeated intercourse."

Dr. Harvey's report includes 372 cases, of which 205 were considered certain and 167 doubtful. Of the 205, one was two years old; one, two and a half; one, three; three, four; five, five; nine, six; nine, seven; eighteen, eight; twenty-one, nine; twenty-six, ten; nineteen, eleven; twenty, twelve; thirty, between twelve and fifteen; and nineteen above fifteen. That is to say, of those whose ages are given, 51 per cent. were under ten, and eighty-nine under fifteen. Five of these cases were fatal, and in twenty-five instances, besides external injuries, laceration of the vagina was found. The perinæum was torn in fourteen cases.

Among the "doubtful" cases, "in sixty instances children from nine to thirteen years of age were reported as 'accustomed to intercourse.'"

Statistics of this kind are fortunately peculiar to India, but they tell a ghastly tale. We have no facts in our possession regarding infant prostitution, but very cursory observation in Calcutta suffices to indicate that females are trained and prepared for a life of vice from a very tender age. It is time that native society bestirred itself in this matter. The evil is one which saps national vigor and national morality. Reform must come from conviction and effort as in every other case, but meantime the strong arm of the law should be put forth for the protection of female children from the degradation and hurt entailed by premature sexual intercourse. This can easily be done by raising the age of punishable intercourse which is now fixed at the absurd limit of ten years. Menstruation very seldom appears in native girls before the completed age of twelve years, and if the "age of consent" were raised to that limit, it would not interfere with the prejudices and customs which insist on marriage before menstruation. This would be a step in the right direction; but we would impress strongly and earnestly on the native community that maturity and not puberty is, on physiological as well as social grounds, the true time and condition of marriage.

The Southern Surgical and Gynæcological Association will meet in Atlanta, Ga., on Tuesday, Wednesday, and Thursday, November 11th, 12th, and 13th, under the presidency of Dr. George J. Engelmann, of St. Louis. Besides the president's annual address, the preliminary programme mentions the following: How shall we treat our Cases of Pelvic Inflammation? by Dr. R. B. Maury, of Memphis, Tenn.; The General and Local Treatment of Gangrenous Diseases and Wounds, by Dr. Bedford Brown, of Alexandria, Va.; A Further Study of the Direct and Reflex Effects of Lacerations of the Female Perinæum, by Dr. J.

H. Blanks, of Nashville, Tenn.; Abdominal and Pelvic Surgery in America, by Dr. Joseph Price, of Philadelphia; Intraligamentous Ovarian Cystoma, by Dr. Cornelius Kollock, of Cheraw, S. C.; The Anatomy and Pathology of the Ilio-cæcal Region, by Dr. Richard Douglas, of Nashville, Tenn.; Wet Antiseptic Dressings in Hand Injuries, by Dr. W. Perrin Nicolson, of Atlanta, Ga.; The Best Route to the Bladder in the Male for Disease or for Foreign Bodies, by Dr. Hunter McGuire, of Richmond, Va.; Suprapubic Cystotomy in a Case of Enlarged Prostate, by Dr. W. H. H. Cobb, of Goldsboro, N. C.; The Indications for Cholecystotomy, by Dr. A. M. Owen, of Evansville, Ind.; Uterine Moles and their Treatment, by Dr. J. T. Wilson, of Sherman, Texas; Strictures of the Male Urethra, by Dr. W. F. Westmoreland, of Atlanta, Ga.; The Treatment of Urethral Strictures by Electricity, by Dr. W. Frank Glenn, of Nashville, Tenn.; The Surgical Treatment of Empyema, by Dr. J. A. Goggans, of Alexander City, Ala.; Cases in Abdominal Surgery, by Dr. I. S. Stone, of Lincoln, Va.; Rectal Medication in Pelvic Troubles, by Dr. W. Hampton Caldwell, of Lexington, Ky.; Conservative Surgery in Injuries of the Foot, by Dr. J. T. Wilson, of Sherman, Texas; The Management of the Infantile Prepuce, by Dr. George B. Johnston, of Richmond, Va.; The Ultimate Results of Trachelorrhaphy, by Dr. Virgil O. Hardon, of Atlanta, Ga.; Further Observations on the Dangers of Operative Delay in Prostatic Troubles, with Personal Experience, by Dr. R. D. Webb, of Birmingham, Ala.; The Clinical History of the Epicystic Surgical Fistula, with Cases, by Dr. J. D. S. Davis, of Birmingham, Ala.; Foreign Bodies in the Air-passages, with Report of Cases, by Dr. John E. Pendleton, of Hartford, Ky.; Cholecystotomy, by Dr. W. E. B. Davis, of Birmingham, Ala.; Two Cases of Laparotomy for Intestinal Obstruction, by Dr. J. T. Jelks, of Hot Springs, Ark.; Is Gonorrhœa Ever a Cause of Pelvic Inflammations? by Dr. J. R. Buist, of Nashville, Tenn.; and papers, the titles of which are not determined, by Dr. W. O. Roberts, of Louisville; Dr. L. S. McMurtry, of Louisville; Dr. W. D. Haggard, of Nashville, Tenn.; and Dr. Hunter P. Cooper, of Atlanta, Ga.

The Fairchild Digestive Preparations are said to have formed a part of the outfit of Stanley's Emin expedition, and articles of food predigested with Fairchild's extractum pancreatis to have been used exclusively by Mr. Stanley during his recent illness.

The New York Pasteur Institute.—Dr. Paul Gibier, director of the institute, informs us of the results of the preventive inoculations against hydrophobia performed at this institute since its opening (February 18, 1890).

To date, 610 persons bitten by dogs or cats came to be treated. These patients may be divided into two categories:

1. For 480 of these persons it was demonstrated that the animals which attacked them were not mad. Consequently the patients were sent back after having had their wounds attended to during the proper length of time, when it was necessary. Four hundred patients of this series were advised or treated gratis.

2. In 130 cases the antihydrophobic treatment was applied, hydrophobia having been demonstrated by veterinary examination of the animals which had inflicted the bites or by inoculation in the laboratory, and in many cases by the death of some other persons or animals bitten by the same dogs. All these persons are to-day enjoying good health. In 80 cases the patients received the treatment free of charge.

The persons treated were:

64	from	New York.	3	from	Pennsylvania.	1	from Ohio.
12	"	New Jersey.	2	"	New Hampshire.	1	" Arizona.
12	"	Massachusetts.	2	"	Georgia.	1	" Iowa.
8	"	Connecticut.	2	"	Texas.	1	" Nebraska.
9	"	Illinois.	1	"	Maryland.	1	" Arkansas.
3	"	Missouri.	1	"	Maine.	1	" Louisiana.
3	"	N'th Carolina.	1	"	Kentucky.	1	" Ontario (Can.).

Intra-uterine Death and Placental Disease.—"Dr. Prinzing, of Munich, has examined a series of placentæ under the microscope, with a view of obtaining fresh knowledge as to the pathology of placental disease. He minutely investigated six specimens; four belonged to dead and macerated fœtuses born at term or prematurely. The histological changes resembled those which have been observed in the vessels of the brain in syphilis. Endoarteritis was marked, and the vascular disease involved plugging, induration of surrounding connective tissue, and calcareous degeneration. The fifth placenta was from a premature birth; the child was dead and macerated. A large white infarct lay in its substance, the result, in Dr. Prinzing's opinion, of coagulation from anæmia. Unlike Ackermann, he attaches less importance to periarteritis in this form of placental disease. In a sixth case, where the fœtus was delivered at the fourth month and was not macerated, intraplacental hæmorrhage was evident even to the naked eye. In the last two cases there was no evidence of syphilis. In all six the diseased condition of the placenta sufficiently accounted for death. The above researches are of scientific interest; diagnosis before birth or abortion is impossible."—*British Medical Journal.*

ANSWERS TO CORRESPONDENTS.

No. 334.—We are not aware of any book that gives them all.

No. 335.—Our impression is that more cases occur in Austria than in any other country. See an article by W. G. Lumley, in the *Journal of the Statistical Society of London*, vol. xxv, 1862, page 219.

No. 336.—We know of none.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Original Communications.

RETENTION OF URINE FROM PROSTATIC OBSTRUCTION IN ELDERLY MEN: *ITS NATURE, DIAGNOSIS, AND MANAGEMENT.**

BY JOHN W. S. GOULEY, M. D.,
SURGEON TO BELLEVUE HOSPITAL.

WHILE urethro-vesical obstruction occurs in young and middle-aged men from bladder and prostate stones, from acute prostatitis, from contracture of the vesical neck due to the extension of chronic urethritis, or from malignant disease of the prostate, it should not be confounded with the gradual and slow process of prostatic obstruction which rarely begins to impede urination before the age of fifty-five and is as rarely known to begin after the age of seventy.

To the question, What is it that causes this impediment to urination in elderly men? a common but incomplete answer is enlargement of the prostate. This answer is incomplete because of its failure to specify the kind of enlargement, for it is known that elongation and also uniform general enlargement of the prostate do not obstruct the urethro-vesical orifice or impede urination. Very large prostates have been discovered after death in elderly men who had never suffered the least inconvenience in urinating and whose bladders were in a normal condition. On the other hand, small prostates—*i. e.*, of even less bulk than natural, with only moderate increase of the lower isthmus, sufficiently obstruct the urethro-vesical orifice to give rise to stagnation of urine, cystitis, and even to complete retention of urine.

It is then only when the prostate is unequally enlarged that it interferes with urination, and to this even there are exceptions, for multiple tumors at its base sometimes cause true incontinence of urine, as do other forms of prostatic enlargement which prevent the closure of the urethro-vesical orifice and allow the urine to flow constantly from the bladder as fast as it trickles out of the ureters. In this connection, enlargement of the prostate, conveying as it does only a general notion that the organ is in an abnormal state, needs to be specified, and it can ordinarily in some measure be specified after due observation of its immediate effects; for instance, an elderly man from whom normal urine is constantly dribbling and who suffers no other inconvenience presumably has true incontinence of urine due to some form of enlargement of the prostate which keeps open the urethro-vesical orifice, while another elderly man from whom fœtid purulent urine is constantly dribbling presumably has chronic retention of urine due to urethral or to urethro-vesical obstruction from some one of the forms of prostatic enlargement specified below, urethral stricture or the impaction of a calculus in the urethra having been excluded.

Of the several forms of unequal enlargement of the prostate which obstruct the urethro-vesical orifice the following only need now be named: (1) General enlargement with excessive development of the posterior third of the lower isthmus, called supra-montanal portion by Mercier and third lobe by Home; (2) enlargement of the posterior third of the lower isthmus without apparent increase in the rest of the prostate, sometimes called centric enlargement; (3) enlargement of one lobe which encroaches upon the opposite lobe and obstructs the prostatic urethra; (4) unequal enlargement of both lobes, rendering the prostatic urethra tortuous and obstructing it; (5) multiple intra-urethral tumors; (6) intra-vesical enlargement of one lobe. Such are the principal forms of prostatic enlargement that impede urination.

These alterations of structure differ somewhat in their component elements. The majority of cases are diffuse leiomyomata, with a very small quantity of fibrous tissue accompanying the blood-vessels, and ectasia of the prostatic crypts, the sympexia of the crypts often dying and becoming coated with phosphate of calcium, and consequently increasing considerably in volume. They are those prostates which are softer than normal and which attain the greatest size. In some cases there are multiple circumscribed leiomyomata. Other cases are of diffuse and circumscribed inomata. They are the small, hard prostates which sometimes contain retention epithelial cysts. Adenomata are not so frequently found as are the myomata and inomata, and are circumscribed.

The first effect of urethral or of urethro-vesical obstruction is stagnation of urine in the bladder. The stagnant urine, even a few drachms, soon decomposes, and, acting as an irritant foreign body, gives rise to cystitis. The inflamed bladder then makes vigorous but vain efforts to expel this offending urine, in consequence of which its muscular coat increases in thickness. In certain cases the larger part of the stagnant urine is expelled, but the small quantity which remains is sufficient to induce such frequent spasmodic contractions of the bladder that the capacity of this organ gradually decreases until it is reduced to only two or three ounces. In other cases the bladder is dilated and capable of containing a quart, or even several quarts, of stale urine. In either class of cases, unless artificial relief be promptly obtained, the consequences are of the gravest order. The urine, thus dammed up, leads to dilatation of the ureters, ureteritis, pyelitis, nephritis, and death.

It may be asked, Is it possible to make a reasonably accurate diagnosis of these several kinds of prostatic obstruction? Yes, at least in four of the six just enumerated, and it is of no little practical consequence that they be differenced, for some of them require modifications in their surgical management.

The early manifestations of prostatic enlargement do not always cause anxiety and are often overlooked. The patient, having perhaps only vague notions of his condition, generally misinterprets the gradually increasing frequency of the calls to urination, does not perceive that his urine is slimy, pays little attention to the slight sensation of scalding during urination, is not aware of the significance of the

* Read before the New York State Medical Association, October, 1890.

changes in the mode of propulsion of the urine, notably the vertical direction of the jet, fails to notice the diminished size of the stream whose sudden cessation induces him to think that the act of urination is accomplished, when, to his surprise, more urine is expelled drop by drop, to be succeeded by the former perpendicular stream and again by the drops, and does not solicit the advice of his physician until all these symptoms are greatly intensified or until he is already distressed by complete retention of urine.

Of the several steps in the diagnosis of abnormal urination and retention of urine due to prostatic enlargement, chiefly the following are employed:

The history of the patient's prior ailments, of his actual infirmity, and of his habits of life, having been obtained, an inspection of his general condition is made. His mode of urinating, if he can urinate, is noted, and his urine is duly examined. Then follows physical exploration.

The first step in this exploration is palpation, then percussion of the hypogastric region. If there is no tumefaction, if percussion is clear, it will be inferred that the bladder is empty or nearly so; and if at the same time it is noticed that normal urine is constantly flowing, it will be fair to infer that there is incontinence rather than retention of urine, although the involuntary flow of urine indicates oftener its retention than its incontinence; but if there is a rounded, tense, and painful tumor, dull or flat under percussion, and with this a constant desire to urinate, the inference will be that there is acute retention of urine. If, however, there happens to be a diffuse, slack swelling with fluctuation, also flatness under percussion, a dull instead of an acute pain, and no urgent desire to urinate, but slobbering of urine, the existence of chronic retention of urine will be inferred.

It is proper to state that, while percussion possesses some value in the diagnosis of retention of urine, it is not to be absolutely depended upon. For example, flatness on percussion does not necessarily indicate the presence of urine in the bladder, for, in the hypogastric region, flatness may be owing to a solid tumor in front of the bladder. Circumscribed flatness and fluctuation may indicate a pelvic abscess as well as stagnation of urine in the bladder, with more or less distention. Resonance on percussion does not indicate absence of retention of urine, for such resonance may be owing to the presence of knuckles of small intestine between a distended bladder and the anterior abdominal parietes.

The second step in physical exploration consists in making a digital examination of the prostate through the rectum, by which some idea may be formed of the size and consistence of the organ. As a general rule, hard prostates are little if at all enlarged, while soft prostates are large and sometimes attain enormous dimensions. By this same digital examination, the form as well as the size of the prostate is estimated. It may be simply elongated; one of its lateral lobes may be larger than the other; it may be uniformly enlarged; it may be nodulated, and this suggests the existence of multiple tumors; or it may not be larger than natural, but its apex may be rounded instead of being insensibly lost in the membranous region of the urethra. These are the principal circumstances to be noted from a rectal exploration.

The third step in physical exploration consists in ascertaining the particular kind of prostatic enlargement which affects urination. The exploration is made by introducing certain metallic instruments through the urethra into the bladder. This method was suggested and practiced by Mercier many years ago, and is as follows: A rectangular, short-beaked metallic sound (Fig. 1) or catheter is slowly

Fig. 1.—Mercier's rectangular sound.

introduced until it reaches the prostatic region of the urethra. If then the handle turns to the right of the patient, it is because the point of the instrument has been deflected by an intra-urethral projection of the left lobe of the prostate, and *vice versa*. If first to the right and then to the left half an inch or thereabouts farther back, it is because the point of the instrument is deflected first by a projection of the left and then by a projection of the right lobe of the prostate, showing unequal enlargement of both lobes. If the sound meets no impediment until it has nearly reached the bladder, and then its blunt heel encounters an obstacle, it is because there is enlargement of the posterior third of the lower isthmus (supramontanal portion, third lobe). By moderately depressing its handle and gently pushing the sound onward, it enters the bladder. Its beak is then reversed, and turned to the right and to the left in order to form some idea of the general character of the obstacle, if there be intravesical projection.

But for greater precision the cysto-pylometer (Figs. 2 and 3) may be used. By means of this simple instrument the thickness of the obstacle can be accurately measured, and it can be ascertained if this consist of a crescentic valvule, of a "bar," or of a sessile or a pedunculated tumor.

Fig. 2 represents the first cysto-pylometer devised by the author. It is so constructed that the vesical extremity of the male blade can easily override any urethro-vesical barrier without giving pain to the patient. This construction of the jaw of the male blade rendering the prehensile part a trifle too short, a new pylometer (Fig. 3) with the male prehensile part one third longer was lately contrived with the view of remedying the defect of the first instrument, but in this new pylometer the inclination of the jaw is so abrupt that it is necessary to observe the greatest care in opening the jaw of the instrument to carry the male part over a urethro-vesical barrier.

The several forms of prostatic enlargement already indicated give rise to acute and to chronic retention of urine.

By acute retention of urine is meant a sudden hindrance to the expulsion of urine from the bladder. It is characterized by great pain in, and an almost intolerable sense of distention of, the bladder; by a scalding sensation in the urethra; and by a constant desire to urinate which seems incessantly on the point of without being gratified.

Acute retention of urine occurs as well among elderly

men with incontinence as among those who have no hindrance to normal urination, or only a very slight impediment—*i. e.*, the beginning of prostatic obstruction.

Fig. 2.—The author's first cysto-pylometer.

Fig. 3.—The author's second cysto-pylometer.

The mechanism of acute retention of urine is as follows: After exposure to cold, venereal excess, or a debauch, the pelvic vessels sometimes become so gorged with blood that the prostate swells, principally in the direction of the urethra and urethro-vesical orifice, to the extent of occluding the passage. This sudden engorgement is soon followed by exudations which do not always entirely disappear. Resolution is occasionally very slow, and even fails; the swollen prostate is then little, if at all, diminished, and acute retention may thus pass into chronic retention of urine.

Acute retention of urine is ordinarily preceded by dysury for an hour or two. Urination is unduly frequent, irregular, scanty, and accompanied with scalding pain in the whole urethra until strangury occurs; then urine mixed with mucus and blood escapes only in drops at each spasmodic contraction of the bladder. Finally, a few hours after the exposure or debauch, comes ischury. The patient is now unable to discharge a single drop of urine and is tormented with violent straining, which favors the escape of fæcal matter and even causes prolapse of the rectum. The passage being entirely occluded, the urine accumulates from hour to hour until the bladder is greatly overdistended and loses its power of contracting, generally for a time only, sometimes indefinitely. At the expiration of the first day the suffering is still very great, the patient becomes more restless, feverish, and thirsty; his face is congested from the constant straining, his skin is dry, and his intestines are distended with gas. On the second day the pain extends to the lumbar regions, and the dryness of the skin is succeeded by profuse perspiration having a urinous odor. The urine then begins to dribble, and this is delusive to the patient and to his family, who imagine that spontaneous relief has come, when in truth the urine is still accumulating in the bladder, a little only slobbering out from overflow. The consequence of this misinterpretation of a symptom is failure to invoke medical aid until it is deemed proper to repress what is wrongly believed to be a superabundant flow of urine. Meanwhile the patient lapses into a muttering delirium, his utterances being obscured partly by the extreme dryness of his tongue and mouth. The secretion of urine is now lessened (oligury), and may soon be abolished (anury), although the bladder is distended to the extent of four or five pints. In some cases the physician is not summoned until many nauseous, useless, and often hurtful nostrums and diuretics have been administered.

In the management of acute retention of urine to temporize or to rely solely upon the use of medicaments in any case is to place the life of the patient in great jeopardy. Having informed himself of the circumstances connected with the case and having made a preliminary examination, the physician selects the form of catheter best suited and forthwith introduces it, allowing the urine to flow very slowly, and every few seconds stopping up the distal end of the catheter. If called during the first twenty-four hours, he may empty the bladder at one sitting of three quarters of an hour, but if on the second day, he should draw off slowly only about one third of the contents of the bladder, and after this once every two or three hours he should introduce the catheter and allow more urine to flow, until in a day or two he finally empties the bladder, or he may leave in the catheter with its distal end closed and direct that six ounces be drawn off every two hours. The reason for these precautions is that the too precipitate evacuation of an overdistended bladder is sometimes followed by distressing and dangerous effects, such as profuse hæmorrhage from its mucous membrane and consequent general cystitis, polyury, etc.

The after-treatment should accord with the particular necessities of the case. The use of the catheter should not be abandoned until the patient is able to empty spontaneously his bladder, which should not again on any account be allowed to become overdistended. If the swelling of the prostate does not diminish, the use of the catheter should be continued indefinitely. In the mean time the urine should be kept bland by the internal administration of diluents, and the bladder should be irrigated once daily with a warm boric-acid solution, three grains to the ounce, with the addition of one fourth of peroxide-of-hydrogen solution.

By chronic retention of urine is meant a gradual and slow hindrance to the expulsion of urine from the bladder. Its characters are not generally perceived by the patient

and are not always manifest to the physician, partly because this retention of urine does not become complete for many weeks or months, or even may never become complete. When incomplete it is at first characterized by much irritability of the bladder, which is constantly wrestling against the obstruction to force out the urine; but this subsides in the course of a few months, when the sensibility and contractility of the bladder are somewhat impaired, as evinced by less painful, less urgent, and less frequent urination, and by the stream being small, feeble, frequently interrupted, and replaced by a succession of drops. When the retention is complete it is characterized by inability on the part of the patient to expel a single drop of urine.

As already stated, chronic retention of urine is the outcome of gradual, progressive, but ordinarily incomplete closure of the urethra or urethro-vesical orifice by unequal enlargement of the prostate which obstructs the canal. From being incomplete, this retention of urine becomes complete when the enlarged prostate further swells to the extent of closing the passage. It again becomes incomplete when from overdistention of the bladder the urethro-vesical orifice opens sufficiently to allow the urine to overflow and slobber out.

The differential diagnosis of acute and chronic retention of urine having been set forth in a paper read before the Medical Society of the County of Kings and published in its proceedings in January, 1882, will not now be discussed.

Grave errors are occasionally made in certain cases of extreme distention of the bladder from neglect to use the catheter as a means of diagnosis, for in elderly men the urine sometimes accumulates so slowly and gradually that the vesical distention causes little or no pain, or the slight pain is attributed to something else, and increases, in the course of weeks or months, to such an extent as to mislead the unwary. Such cases have been confounded with ascites, with abdominal tumors connected with the omentum, intestines, liver, or kidneys, with hydatids, with hydronephrosis, and even with fæcal impaction. In one instance a trocar was plunged into the abdomen, two inches below the umbilicus, the physician believing the case to be one of hydatid cysts, and seven pints of fluid drawn, which proved to be urine.

To the question, What is the most suitable catheter in cases of retention of urine from prostatic obstruction? the reply is that one catheter can not answer in all cases. The catheter should, as far as possible, be adapted to a particular kind of obstruction. Therefore the physician should be supplied with several very different catheters, and, after due exploration, as before indicated, be able to select one which is adapted to the particular deformity found in the prostatic region.

For exploration the metallic instruments already described should be used, but after this, and for evacuative catheterism, metallic catheters should be avoided, for it is by their use that false passages are so commonly made. The most dangerous among these is the so-called prostatic catheter of great curve and extra length. The main difficulties in catheterism, as a general rule, are not due to increased length of the prostatic urethra, but to its several deviations; and a rigid catheter of great curve, even when used with caution, ordinarily fails to pass, besides being very apt to tear the urethra.

The catheters which are indispensable in the physician's armamentarium, all but one—*i. e.*, the soft, vulcanized India-rubber "velvet-eyed" catheter—consist of a tubular fabric of silk, coated with a pliable material, with a single eye close to the vesical extremity; the form of this extremity being in accordance with the particular use to which each instrument is designed. The most useful are the five forms indicated below.

The catheter (Fig. 6) woven upon a curved stylet is well adapted to cases of moderate supramontanal (centric) enlargement, or of urethro-vesical bars. When greater curvature is needed, as in a case of very large tumor of the supramontanal region, or when a false route impedes catheterism, a stylet may be inserted, and the catheter introduced after the method of William Hey. This efficiently replaces the so-called prostatic catheter. All the pliable catheters are from twelve to fourteen inches in length.

The olivary catheter (Fig. 7) is also woven upon a curved stylet; but the straight olivary catheter, very pliable for an inch from the point to the eye, is useful in cases of extremely tortuous urethræ from unequal enlargement of both prostatic lobes.

The elbowed catheter of Mercier (Fig. 4) is particularly well adapted to cases of intra-urethral tumors, of uni-

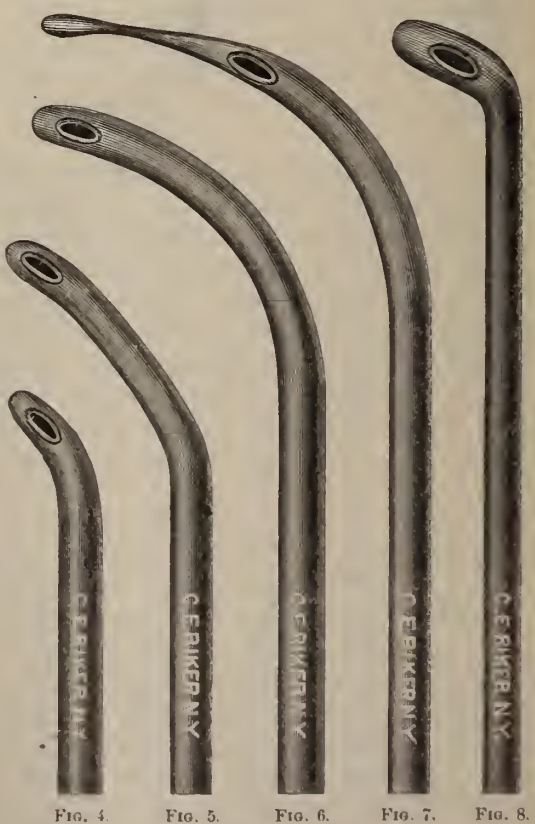

Fig. 4. Fig. 5. Fig. 6. Fig. 7. Fig. 8.

lateral enlargement, or of unequal enlargement of both lobes of the prostate, but is also successfully used in cases of urethro-vesical barriers.

The crutched catheter (Fig. 8), more angular than the elbowed, answers well in cases of great enlargement of the supramontanal region, the heel instead of the point of the instrument coming in contact with and gliding over the obstacle.

The double-elbowed catheter of Mercier (Fig. 5) is adapted to cases of enlargement of the superior isthmus, together with supramontanal increase, causing great depression of the floor of the prostatic sinus.

Respecting the size of the catheters, the question, Should they be small or large? is very commonly asked. The answer is that they should be neither large nor small, but adapted to the particular urethra to be catheterized. A catheter of full size for a urethra under the average is too small for a urethra of extraordinary large caliber. A No. 14 (English) is small for the latter, and entirely too large for the former, to which a No. 7 (English) is likely to be much more suitable. These, however, are extreme cases. The most convenient size to the physician and to the patient, one that strikes a fair average, is No. 9 (English). It is rare to find urethræ that will not admit a No. 9, particularly in cases of stagnation of urine from prostatic obstruction, stricture being excluded. Many patients who are obliged to catheterize themselves labor under the delusion that small catheters are safest and give least pain. To the use of small catheters may be ascribed the majority of prostatic false routes and the frequent attacks of urethritis and orchitis from which auto-catheterists suffer. The best sized and safest catheter for each individual is the catheter that moderately fills and therefore does not stretch the urethra. Such an instrument gives less pain than the too large or the too small catheter.

The India-rubber "velvet-eyed" catheter is ordinarily the safest for general use by the inexperienced and for auto-catheterism, but its long-continued use upon or by the same patient is not advisable. The security felt by the patient is often a source of danger, for he is soon heedless of the precautions advised by the physician and suffers much in consequence. How much more frequently the physician is called upon to remove from the bladder fragments of or entire India-rubber catheters than of other firmer instruments! But, aside from these accidents, the urethra is often greatly irritated by the rubber catheter, not on account of this material itself, but of the carelessness, boldness, and undue frequency of its use, which come of its easy introduction. Painstaking, prudent, and intelligent patients soon acquire sufficient skill in the use of any of the several pliable catheters and learn to keep them in good order.

An important advantage of the India-rubber catheter is that it can be kept in an aseptic condition without injury to its structure. Very lately Vergne, a Paris manufacturer, has announced that he has succeeded in making pliable catheters which are susceptible of being rendered aseptic without injury.

It frequently happens that the physician is called upon to relieve patients from retention of urine when ordinary catheterism is impossible by reason of false passages in the prostatic region. In such cases the common practice has been to make a suprapubic puncture with an ordinary trocar and insert a catheter or a silver tube, to be opened as often as necessary for urination. Twenty years ago capillary puncture with aspiration was introduced to the profession by Dieulafoy, and this novelty soon became the fashion. Many successful cases were reported, and capillary puncture with pneumatic aspiration was to be *the* operation in retention of urine. Although at first no reference was made to accidents, in a few years the vogue of the process was on the wane; now it is employed with more discrimination, and only to relieve extreme distention once or twice, and not ten, twenty, or thirty consecutive times in the same case. Capillary puncture with pneumatic aspiration is an excellent resource in medicine and surgery; it can not be too highly praised, but its abuse should be loudly decried.

No kind of puncture of the bladder ever can remove a false route, and capillary puncture is not so safe a process as was at first believed. The consequences of the escape of a few drops of urine in the prævesical connective tissue have been so disastrous in a number of cases as to deter cautious physicians from employing this method of relief except under circumstances of the greatest urgency; but there is an equally forcible objection to its general employment—to wit, a simple, safe, and efficient procedure has existed for the past forty years. Why it has not been more frequently employed is not apparent, but it is nevertheless valuable. In the year 1850 Dr. Mercier published in the *Union médicale* an account of his invaginated catheter for use in cases of prostatic false routes. Descriptions and drawings of the instrument have appeared in different books and periodicals, but little heed seems to have been otherwise taken of this precious device. It may be fairly stated that in ninety-five per cent. of cases of prostatic false routes the invaginated catheter can be successfully applied. The instrument (Fig. 9) as now made consists of two catheters—

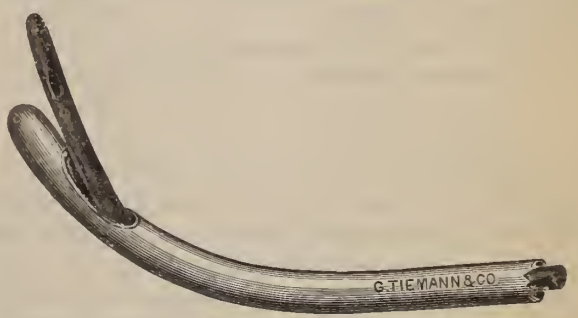

Fig. 9.—Mercier's invaginated catheter.

one metallic, the other non-metallic. The first or female part is a thin-walled No. 10 (English) silver catheter eleven inches long, very slightly curved, and having in its concavity, about half an inch from the point, an oval eye five eighths of an inch in length and three sixteenths in breadth. From the vesical extremity of the eye is an inclined plane, which is lost in the floor of the opening at the distance of a quarter of an inch, serving to tilt up the point of the male part. This male part is a flexible but firm "gum" catheter (No. 7 English) eighteen inches long, fitting loosely in the lumen of the female part, and having a single eye an eighth of an inch from its point. The way to use the invaginated

catheter is to introduce the male into the female part as far as the eye of the latter, then to pass the instrument as far as the obstacle and engage the point of the metallic part in the false route, and finally project the male part, which will override the false route thus blocked and enter the bladder. If no urine should flow, it would be owing to closure of the eye of the male part by a blood-clot, which might be forced out by the injection of a little water through the male catheter. The female part can then be withdrawn and the male left in as long as may be required; this is the reason for the increased length of the male part.

In twenty cases the author has resorted to divulsion of the prostatic false route during catheterism with the invaginated catheter. This process, though comparatively easy, is not advisable except in the most experienced hands. While the immediate result has generally been good, it has not been lasting, for he has not known spontaneous urination to continue more than two years in any case after this operation.

The management of ordinary cases of chronic retention of urine from prostatic obstruction, without false routes, may be summarized as follows: Catheterism having been successful, only a part of the stagnant urine should be drawn off, and the bladder not completely emptied for a day or two, and sometimes not for a week, but the quantity of retained urine should be lessened every day. Then the bladder should be daily washed. In many cases it is not wise to begin at once with irrigations, or to use them too frequently. Bladders that have long contained purulent, slimy urine do not bear the contact of limpid fluids of low specific gravity well at first. It is therefore necessary to increase the density of the water used for vesical irrigation in such, and, indeed, in the great majority of cases. A good formula for vesical irrigation is the following, after dilution of one in twenty:

℞ Hydrarg. chloridi corrosivi... gr. v;
Ammonii chloridi..... gr. xx;
Spir. gaultheriæ..... fl ℥ ss.;
Acidi borici..... ℥ j;
Glycerini..... fl ℥ viij. M.

To half a fluidounce of this solution are added seven fluidounces of warm water (110° F.) and two fluidounces and a half of peroxide-of-hydrogen solution.

These ten ounces of fluid are sufficient for four washings of two ounces and a half at each sitting. Only in very exceptional cases should the bladder be irrigated more than once a day. After the bladder has been completely emptied, evacuating catheterism should be employed every five or six hours, except in cases of contracture with diminished capacity, when the catheter may be needed every two hours. In these cases it is necessary to resort to gradual hydraulic dilatation, a very delicate operation, which is successful when there has not been too long continued cystitis with connective-tissue sclerosis.

The general treatment in cases of stagnation of urine should be conducted in accordance with sound hygienic principles and little else. Opium, belladonna, or hyoscyamus should be used only to relieve extreme pain and spasm. The urine should be kept bland by the use of diluent beverages and the rectum completely emptied every day, for, next to stagnant urine in the bladder, the accumulation of fæces in the rectum is the greatest source of discomfort. A little generous wine at dinner, and a drink of brandy or whisky and water at bed-time, may be allowed without fear of causing local irritation; it is only in excess that alcohol is hurtful in these as in all circumstances.

The question of prostatotomy and prostatectomy, internal and external, will not now be discussed, but a few words will be said of circumstances under which a portion of the prostate may be excised during suprapubic cystotomy for a tumor or stone. When epicystotomy has become necessary for the extraction of a stone or the ablation of a morbid growth, it may be proper to excise a portion of the prostate or a pedunculated prostatic tumor projecting in the bladder and interfering with urination. Pedunculated tumors can be excised by means of scissors with rectangular blades; but if a bar or median outgrowth is to be cut, the rectangular intravesical, suprapubic prostatcetome (Fig. 10), constructed on the principle of the hawk-bill scissors of Dr. Skene, will be found to answer the purpose of excising as considerable a portion of the prostatic obstruction as may be desired, leaving a V-shaped chink for the escape of urine.

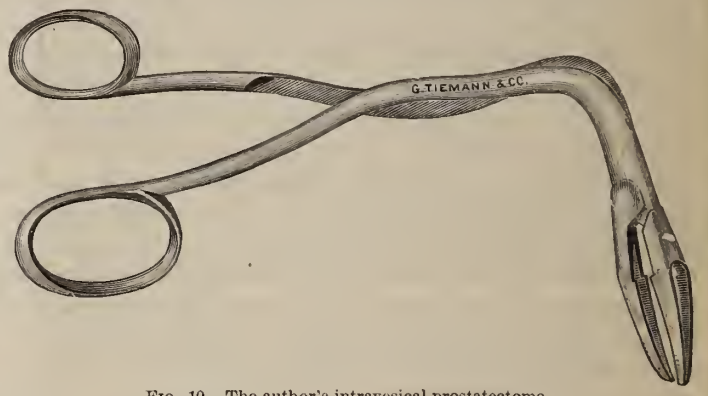

Fig. 10.—The author's intravesical prostatectome.

The removal of a urethro-vesical tumor of the prostate during suprapubic lithotomy was done about half a century ago by Amussat.

HOARSENESS AND LOSS OF VOICE CAUSED BY WRONG VOCAL METHOD.*

By S. W. LANGMAID, M. D.,
BOSTON.

Such a case as the following often presents itself in my own practice, as I suppose it does in the practice of all who see many singers' throats.

A young person, generally a female, complains of hoarseness, of difficulty in producing such tones as still remain to the singing voice, of a constant tired feeling in the region of the larynx, and of aching or pain there after singing.

The history is generally as follows: The patient is a

* Read before the American Laryngological Association at its twelfth annual congress.

student of vocal music. Before commencing the study of vocalization she sang freely, thoughtless of her manner of doing so, with no sense of fatigue, but, on the contrary, with a feeling of physical enjoyment; in fact, as a child of musical aptitude and a naturally good singing voice always sings.

Very soon after beginning to receive instruction she began to experience some of the above-mentioned symptoms, and the highest notes of the voice were produced with increasing effort. After a time these high notes were lost, and at last the speaking as well as the singing voice became hoarse. To such a recital is added the remark that before taking singing lessons there had never been any throat affection or hoarseness.

The examination of the throat reveals perhaps a moderate naso-pharyngitis and a catarrhal laryngitis, and, upon attempted vocalization, one or both vocal bands are seen to be paretic. The closure of the cartilaginous and ligamentous glottis is imperfect and there is defective tension.

Now to the patient as well as to the physician such a history and such appearances reveal nothing more than a catarrhal affection of the mucous membrane, and consequent paresis of the laryngeal muscles, caused by hostile climate. Especially would this be likely if the patient had formerly resided in an inland region and was pursuing her studies in a seaboard or lake city. Of course, under any circumstances, the first command given by the physician would be entire rest of the singing voice and as much as might be possible of the speaking voice also.

The ordinary treatment for the catarrhal condition would be instituted, and, should the paresis not disappear, faradization and strychnine would probably assist the action of the vocal bands and help to restore the quality and capability of the voice.

Such a result will naturally lead to mutual congratulations. But should the cure prove to be short-lived, and the same treatment be required almost as soon as the lessons or practice are resumed, the physician and patient may well ask if a disease which yields so readily to rest and almost routine treatment in an otherwise healthy young person has not some causative factor besides atmospheric conditions.

The natural inference would be that singing had something to do with it. Now singing, properly performed, never injured a healthy throat. I believe, on the contrary, that declamatory exercises and singing are not only restorative to throats which have congestive tendencies, but are also most efficient in preventing catarrhal inflammations. If this is true, and I think no one will dispute it, the decision will not be that singing must be abandoned, but inquiry must be made with regard to the manner of using the voice.

Let it not be said that this is not within the province of the medical adviser. Granted that the laryngologist is not expected to teach vocalization, it is, nevertheless, the fact that the anatomy and physiology of the vocal organs are his daily study.

Most of us are fully competent to detect a wrong physiological procedure by inference, if not by the result which special training or a musically appreciative ear instantly stamps as vocally wrong—that is, physiologically wrong. To abandon the practice of singing may entail in our patients great individual deprivation, as well as loss to a community, small or large, as the case may be.

The medical adviser in the case described above will not be able to prevent the return of the morbid conditions except by determining the fact that wrong use of the voice is probably the cause of its deterioration.

And now it may be properly asked of me to show how the voice has been improperly trained or used.

First of all, let me say that the defects in vocal production are many, and the various wrong ways of singing are almost numberless. The peculiar morbid conditions of the throat which I have described are most frequently caused by the instruction which is given by some teachers, and not infrequently inculcated by treatises on singing, that the tongue should be forced to lie flat in the mouth during vocalization.

If I should assert that this was wrong, I should simply answer one dogmatic assertion by another. Therefore we must examine the mechanism of the natural emission of tone, and contrast this with what we have found will produce the diseased condition which we have described.

A different position of the laryngeal parts is demanded for each note of the scale. In a previous paper I have said that the muscular arrangements of the larynx are capable of adjusting the position of the larynx for every note of the scale independently of the action of the breath. In order that these adjustments may take place rapidly, there must be no hindering, opposing action of antagonistic muscles.

The theory which induces the teacher to insist upon the depression of the tongue is that the cavities of the mouth and pharynx are thereby enlarged, and the corollary is that the larger these cavities are the larger the tone is. Not only is this deduction erroneous, but, if true, the method employed would be the least suited to gain the desired result.

The attempt to depress the tongue necessarily causes tension of the posterior and especially of the anterior pillars of the pharynx, and the isthmus faucium is thereby narrowed. Whatever may be the explanation, the fact remains that such instruction is given by many teachers, and the effects are as pictured above.

Forced flattening of the tongue prevents the necessary free movement of that organ as well as of the jaw and the velum palati. The epiglottis is bent backward and the larynx is driven down and held in a constrained position.

We know that constant alteration in the shape of the mouth takes place during singing, because its shape varies for every different vowel sound.

We all witness, many times each day, that the base of the tongue changes its position or form with each different vowel sound which the patient is asked to produce during the ordinary laryngoscopic examination.

To insist that the root of the tongue should remain flat in singing the vowels *e* and *i* (Italian) is demanding that opposing, hindering muscular efforts shall be put into ac-

tion; moreover, the natural, frank emission of these vowels is impossible. To *hold* the tongue flat for such vowels as are *naturally* produced with a lower position of the tongue and larynx, *a* and *u* (Italian) is to prevent the free action of the muscular adjustments which are necessary for every successive note of the scale.

So far I have spoken only of the effects of this evil instruction upon the pharynx and the laryngeal movement *en masse*. The constrained and unnatural positions into which the pharyngeal muscles are forced will largely account for the catarrhal processes, but the greatest injury is produced within the larynx itself.

I have said that a different adjustment of the laryngeal parts is demanded for each note of the scale. That a variation in the action of *intrinsic* muscles is necessary is proved by the changed appearance of the glottis with every group of notes which constitute the so-called registers. At a certain note of the scale, differing with the character of the voice—soprano, contralto, tenor, etc.—a well-marked change in the shape of the glottis is perceived by the mirror.* The cartilaginous glottis is closed and the vibration is confined to the ligamentous portion. Again, the shape of the ligamentous glottis changes as the scale is sung upward. Now, all these changes in the shape of the glottis are produced by changing muscular action.

If we consider how rapidly these changes occur we must admit that no restraining force, by opposing muscular action, can be permitted. Add to this the variation in the longitudinal tension of the bands and we need say nothing further with regard to the freedom of action which is demanded for all laryngeal movements.

The fatigue of the intrinsic laryngeal muscles which results in a real paresis arises from the unnaturally forced endeavor of these muscles, together with their assisting extrinsic ones, to form the glottis into the proper shape for the production of the different tones of the scale; for, if the position of the larynx is not the natural one for the production of any note, the glottis-shaping muscles can not perform their function unassisted, and the help of the increased wind-blast is called for.

The contest can not be carried on forever, and sooner or later the tired muscles are incapable of the required contracting force, and tension, as well as adducting power, is lost. The cartilaginous and the ligamentous glottis of one or both sides remain inactive, and congestion of the relaxed bands and an open glottis result. I might stop at this point, but I can not refrain from the brief citation of a few cases which seem to illustrate my argument.

In two cases I have seen extravasation of blood under the mucous membrane of the vocal band—a condition which I venture to call the spirit-level form of hæmorrhage, for the globule of blood during phonation changes its position as the drop of air in the level does at any departure from the horizontal. I first saw this extravasation in the vocal band of a young lady who was being taught to force the tongue flat while singing. I saw the same condition in the vocal band of a favorite actor, whose wonderful character acting has astonished and delighted the public for a few years past. The rôle in which he has been so successful demands a double impersonation—the constant use of a peculiar low voice, quickly alternating with a quite different higher voice of contrasted timbre. The extraordinary low voice is evidently produced by forcing down the larynx, while the result is great vocal fatigue and, certainly on one occasion, has been hæmorrhage into the substance of the vocal band.

Case of a Young Tenor.—A few months ago a young tenor desired my advice for exactly the conditions which have been described in the beginning of this paper. It so happened that for two or three years I had listened to his singing and had had abundant opportunity to know that his voice was a true tenor of large compass and of pleasing quality, but for some months past I had noticed that it had lost much of its brilliancy and purity, and that the upper tones were sung as if with unusual effort. Upon inquiry, I found that he had been studying with a teacher who had insisted that all the different vowel sounds should be sung with flat tongue and low larynx. Abstinence from singing and the complete abandonment of the vicious instruction, together with the usual treatment for the catarrhal inflammation, quickly restored the natural quality and compass of the voice.

What has been so far said is the result of my own observation and belief. It is agreeable to find corroboration in the writings of teachers and physicians. With your indulgence I will make but two quotations which seem too apposite to be omitted.

Patton says:* "But the aim of all vocal practice consists in establishing perfectly normal relations between the motor power and the cords. Now, this result is only to be reached by the absence of all undue efforts; and, whereas certain vocal theorists, who rely wholly for success on various muscular movements, may occasionally produce some local benefit, yet in general they impart to the pupil an idea that singing is laborious work, and the latter seldom reaches, judging from experience and various instances, the case of tone-emission which is a charm both for the singer and the listener. Therefore, would it not seem far better, as a general rule, that the vocal scholar were told to think as little as possible about his tongue, for instance, excepting to let it alone and at rest, relying for vocal effect exclusively on the correct breath action? . . . Let the vocal student learn to open his mouth with the utmost ease. Let him learn to drop the lower jaw in uttering a tone with the same absolutely unconscious ease, even as the eyelids drop apart, and let him in this natural way develop any other set of muscles called in play for vocal purposes in the most gentle manner, ever remembering how quietly Nature performs all her normal functions. I desire to impress it on the minds of vocal scholars that any abnormal and strained muscular gymnastics for vocal purposes—as, for instance, the pulling up and down of the larynx as a whole, apart from its natural movements, as in swallowing, etc.—must be pernicious, because all such movements are unnatural in singing. The muscles involving the production of the

* Although this change is not so exact as would appear from the foregoing statement, it is sufficiently so for the argument.

* *The Art of Voice Production*, New York, 1882, pp. 84 *et seq.*

voice are *instinctively* set to work, and their wonderful adjustment far surpasses all human conception and ingenuity."

Sir Morell Mackenzie* writes:

"If the master persists in making the pupil sing in a way that is *felt* to be a severe strain, if every lesson is followed by distressing fatigue of the laryngeal muscles, pain in the throat, or huskiness of the voice, then I say, whatever be the authority of your instructor, do not listen to him, but rather heed the warning that is given you by your overtaxed organs."

I am aware that the picture I have drawn exhibits fatigue of the vocal organs and is to be treated as such, but it is not fatigue caused by the legitimate or necessary use of the voice, which may occur to the best singers from the exigencies of the exercise of their profession. It is a fatigue which occurs from wrong vocal training, and has ruined many a good voice.

The pupil is ignorant and trusting, and the teacher conscientiously inculcates a method which, so far as I know, always produces injury. The physician must heal and restore the injured organ, and, if possible, prevent recurrence of the diseased condition. It seems to me that he should warn the pupil that unnatural, unphysiological processes will render his treatment abortive.

OBSERVATIONS ON THE VARIABILITY OF DISEASE GERMS.†

By THEOBALD SMITH, Ph. B., M. D.,
OF THE BUREAU OF ANIMAL INDUSTRY, DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C.; LECTURER ON BACTERIOLOGY IN THE COLUMBIAN UNIVERSITY MEDICAL SCHOOL.

The problems relating to this subject may, for convenience, be grouped under three heads:

1. The variation of a given species at will in the laboratory by subjecting it to special conditions.

2. The observed variation of a given species in nature.

3. The relation to one another of bacteria which can not be distinguished by our present tests, but which produce disease in different species of animals.

Under the first head I might cite, by way of illustration, the investigations of Pasteur on vaccination of anthrax and rouget, those of Chauveau on anthrax, etc.

Under the second head I might cite a number of observations now on record. Thus recent investigations of Brieger and Fränkel have shown that diphtheria bacilli from different sources are liable to vary in virulence as well as in intensity of growth on culture media. I have observed marked variation in the virulence of swine-plague bacteria from different epizootics. In cultures of glanders bacilli I have noticed considerable variation in the intensity of growth and production of pigment. Among saprophytes this tendency to vary is still more pronounced.

The problems arising under the third head are very puzzling, and their provisional interpretation has a determining influence upon our conception of the origin and distribution of certain infectious diseases. We know, for example, bacteria, such as the bacilli of mouse septicæmia and rouget, which, as regards appearance and pathogenic properties, are certainly very closely related. One is the cause of a disease of swine in Europe, the other is occasionally present in putrefactive substances and is fatal to mice and pigeons. A still better illustration is furnished by a large group of diseases among animals, including some cattle diseases (*Wildseuche* of Bollinger), fowl cholera and swine plague, which are caused by bacteria very closely related—in fact, scarcely, if at all, distinguishable from one another. Can the germ of one of these diseases produce epizootics of another at any given moment and under certain conditions, or are the barriers which separate these germs insurmountable? If we admit the former—if, for instance, we grant that fowl cholera can give rise to swine plague under certain conditions—we evidently regard the germs of these diseases simply as varieties of one species. If we regard the diseases as wholly distinct and not convertible one into the other, we must consider the respective germs as distinct species.

Without delaying to discuss these problems or express any opinions which I may hold temporarily concerning them, I pass on to the subject of this communication.

Several years ago I presented a brief paper to this Section in which I described a variety of the hog-cholera germ, which presented the minor peculiarity of forming speedily a membrane on the surface of liquid culture media, a feature not possessed by the hog-cholera germ found by me in 1885. This fact, although of apparently slight significance to-day, was of more importance at that time, since our conception of disease germs, formulated by Koch and his school, endowed germs with little if any capacity to appear under varying characters. Since that time, as I have pointed out before, slight variability among disease germs has been detected by many observers.

Early in 1889 an epizootic came under my observation from which I obtained a bacillus departing still more from the original type. It is beyond the scope of this paper to give in detail the biological, morphological, and pathogenic characters of the hog-cholera bacillus. I must refer you to the published reports of the Bureau of Animal Industry, especially those of 1885 and 1886, for this matter. I shall simply refer to those points necessary to bring into relief the differences between the two germs to be compared. I shall designate the original germ of 1885, since found in a large number of epizootics in different parts of the country, as bacillus α, that of 1889 as bacillus β. I should add that neither of the germs has anything in common with the swine-plague germ, which, in truth, belongs to a wholly different group of bacteria.

If I were asked to state in a general way the difference between bacillus α and bacillus β, I should say that the bacillus β was in every way nearer the saprophytic stage than α. This is readily apparent from the following considerations:

On gelatin plates, β grows more rapidly, its deep as well as surface colonies attain much larger dimensions than

* *Hygiene of the Vocal Organs*, p. 103.

† Read in the Biological Section of the American Association for the Advancement of Science, August, 1890.

those of *a*, the surface colonies frequently reaching a diameter of four to five millimetres, while those of *a* usually show little, if any, tendency to spread out. In alkaline bouillon with peptone, *a* barely clouds the liquid, while *β* produces a high degree of turbidity. In other culture media there are no differences perceptible. Bacillus *β* in cultures appears slightly larger than *a*: in the tissues of animals, however, the difference in size is not appreciable.

Bacillus *β* has much less pathogenic power than *a*. Pigs are readily infected with a fatal disease when fed with bouillon cultures of *a*. When fed with cultures of *β* they become very sick, but recover within a week. Only one succumbed to feeding, and in this case the bacilli had penetrated the body only as far as the mesenteric glands.

When we come to smaller experimental animals, the rabbit is perhaps the best to illustrate the differences between *a* and *β*.

When inoculated subcutaneously with bacillus *a* (as little as one millionth of a c. c. of a bouillon culture has been sufficient to produce a fatal disease), the rabbit dies within from seven to ten days. The temperature rises 4° to 5° F. from three to four days before death. At the autopsy the spleen is found very large, due to blood engorgement; in the liver are small foci of yellowish necrotic tissue. The kidneys have undergone parenchymatous inflammation. The urine contains albumin and casts. The heart muscle is far advanced in fatty degeneration. Peyer's plaques in the small intestines are frequently reddened. There are usually hæmorrhagic patches in the duodenum at the pylorus. The bacilli are present in all the organs and in the blood.

When I came to test bacillus *β* on rabbits I was astonished to find that they remained alive even after the injection of a quarter of a c. c. of bouillon culture. It had not happened to me since the discovery of the germ, with the probable exception to be mentioned farther on, to find rabbits survive inoculation. I soon found, however, that the injection of a minimum dose into an ear-vein ($\frac{1}{50}$ to $\frac{1}{100}$ c. c.) gave rise to a fatal disease which differed in the following particulars from the disease as described above: It lasted nearly a week longer. The spleen was not enlarged; the necrotic foci were not found in the liver; there was no hæmorrhage in the duodenum, but, on the other hand, a striking disease of the intestines was present. The Peyer's patches of the small intestines were very much thickened and appeared as aggregations of whitish dots. The mucous surface over these patches was not infrequently covered by a slough. In the appendix vermiformis, part or all of the solitary follicles were enlarged, whitish, nodular, occasionally ulcerated. The Peyer's patches at the ileo-cæcal valve —one in the ileum, the other in the cæcum—were, as a rule, much thickened and covered by sloughs. In several cases the mucosa of the cæcum was covered with ulcers, probably due to bacilli discharged from the ulcerating Peyer's patches and localized here. The bacilli were readily demonstrated in the form of clumps in the infiltrated Peyer's patches and in all the internal organs. The disease might be denominated typhoid fever of rabbits.

The question will be asked, Was this really hog cholera and not some other disease like it? In swine the disease from which the bacillus *β* was obtained was identical with hog cholera as usually observed, with the exception that it lasted somewhat longer, and seemed to affect the digestive tract much more severely than the hog cholera of former outbreaks did.

The following results of experiments which can only be summarized here show that we really have a less virulent form of hog cholera before us:

1. When through attenuation by heat, according to Pasteur, bacillus *a* was so modified as to produce a prolonged disease in rabbits, the same post-mortem lesions were obtained as those produced by *β*.

2. When the disease produced by *a* was prolonged by making the rabbit less susceptible (by vaccination with *β*), the intestinal lesions were likewise present.

3. A series of investigations have shown that rabbits protected by two inoculations of bacillus *β* have resisted inoculation of bacillus *a*.

These results indicate not only that the disease produced by *a* is convertible into the disease produced by *β*, but that *β* may be used in rabbits as a vaccine for *a* when the dose is chosen sufficiently small. In short, the disease produced by *β* is simply a more chronic type of hog cholera in rabbits than that caused by *a*.

I might proceed to draw a great many inferences and lessons from this clear case of variability of a most interesting pathogenic organism, but a few of the most important must suffice. In the first place, the tendency to vary enhances the difficulties surrounding the differentiation of bacteria, especially when the test of animal inoculation upon which so much reliance has been placed should not prove a final test.

As an illustration of this difficulty I may cite a personal experience of my own. Several years ago I was directed by Dr. Salmon to make an investigation of an epizootic of swine disease in one of the Eastern States. From two cases I isolated a bacillus which, though resembling the hog-cholera germ, was not quite like it, and it did not prove fatal to rabbits on subcutaneous inoculation. I was unable to come to any conclusion as to the nature of the germ at the time. When more than a year later I became acquainted with bacillus *β*, I again carefully looked over the notes of this investigation, and, although the cultures had in the mean time been discarded, I felt confident that I had at that time the bacillus *β* in my hands. This tendency to vary also enhances the difficulties arising between observers in different parts of the country. One may find one variety, another a second, and when to this difficulty are added insufficient preparation for such work, hasty conclusions, faulty and incomplete descriptions of experiments as actually performed, of facts as actually observed, mutual distrust is the result.

When we come to such germs as the typhoid-fever bacillus, for which tests upon animals have thus far proved useless, because the bacilli seem to have little or no effect on them, the difficulty of pronouncing a given bacillus the genuine typhoid bacillus or not in the face of possible variation becomes very great, especially when we consider that such investigations have a very great influence upon the

administration of public health. The remedy in such cases consists in a thorough, exhaustive knowledge of all the biological phenomena of any given germ.

The experiments with bacillus β on rabbits, which have shown that a veritable typhoid fever may be induced in rabbits, illustrate once again the care which must be exercised in the interpretation of the results of animal inoculation. In the early days of bacteriology an observer might have readily come to the conclusion that this bacillus β could produce typhoid fever in man because it caused ulceration of Peyer's patches in the rabbit. And indeed a prominent observer in this country did make such a diagnosis a few years ago, when inoculation of some germ into cats revealed some lesion of these patches.

The discovery of bacillus β has furnished the means of grouping the hog-cholera bacilli (at least provisionally) with a very common saprophyte living in the intestinal tract of animals, the *Bacillus coli communis* of Escherich. If gelatin plate cultures are made of the contents of the intestines, especially the rectum, of slaughtered healthy cattle and swine, colonies of this bacillus will largely predominate—in fact, superficial observers might consider the fæces as a pure culture of this bacillus. This is not true, however, as there are many forms present which fail to multiply in gelatin. This bacillus may thus be considered a regular inhabitant of the intestinal tract. The bacillus β stands between α and the *Bacillus coli*, forming, as it were, a connecting link. The most obvious differences between the hog-cholera bacilli α and β and the *Bacillus coli*, barring a slight difference in the form of the colonies on gelatin, are the feeble pathogenic power of the latter and its power to cause coagulation of milk by splitting up the milk sugar. The *Bacillus coli* sometimes penetrates into the internal organs in swine diseases, where I have several times detected it during the past three or four years. The dangers of confounding it with the true hog-cholera germ are, therefore, not insignificant. In grouping these forms together I am far from implying that the *Bacillus coli* can be converted into the hog-cholera bacillus, and thus be an ever-present source of hog-cholera germs. The change of saprophytic into parasitic or disease germs probably goes on as slowly as changes in higher organisms, and has nothing sensational about it. The theoretical advantages of thus grouping organisms together will be admitted by all biologists. But there are certain practical advantages most easily discerned by the active worker. We are put on our guard not to confound organisms which may be mistaken for one another, but which are really quite unlike. On the other hand, the facts which have been presented to you show that the danger of keeping apart organisms which in reality belong together is almost as great as that of failing to distinguish between them. In any case, as I have suggested before, a thorough knowledge of all the biological phenomena of groups of organisms, some of which may be pathogenic, some not, and a true sense of the relative value of different properties which are variable will, I think, generally guard us from falling into extreme errors. Finally, in bacteriology, as in the older departments of research, it is the care we bestow upon apparently trifling, unattractive, and very troublesome minutiæ which determines the result.

In the prosecution of this work I received valuable aid from my assistant, Dr. V. A. Moore, as well as from the veterinarian of the Experiment Station of the Bureau, Dr. F. L. Kilborne.

A CASE OF DOUBLE EMPYEMA.

DOUBLE PLEUROTOMY: RECOVERY.

By GEORGE R. WESTBROOK, M. D.,
BROOKLYN.

In the *Transactions of the American Pædiatric Society*, 1889, Dr. Francis Huber, of New York, reports the history and treatment of two cases of double empyema that came under his observation, in both of which the patients recovered; and gives a list of several others, which are about all the cases that have been reported, so far as I have been able to find.

As these cases are seldom seen, and, as recovery is probably not the usual termination, the following case, coming under my care last spring, is of interest:

February 15, 1890, was called to see F. M. P., female, aged four years; was told that the day before she had walked across the river on the Brooklyn Bridge, about a mile and a quarter. During the night she was ill with symptoms of croup; the family had used some domestic remedies, which had partially relieved her. I found her with a croupy cough, slight dyspnœa, and slight rise in temperature; prescribed one tenth of a grain of calomel every hour; saw her again in the evening, when the croupy symptoms had disappeared; the cough was then loose and the temperature normal, and she was feeling quite comfortable.

Next morning found her with a dry cough, temperature 101°, pulse 120, respirations 40, and complaining of pain in her right side. On examination, found dullness on percussion and bronchial breathing over lower lobe of right lung. Diagnosticated pneumonia.

20th.—Coughs a great deal; cough is loose, but she does not expectorate. Temperature 100°, pulse 120, and respirations 48.

22d.—Her condition is about the same. To-day Dr. F. H. Stuart saw her in consultation and confirmed the diagnosis of pneumonia.

March 1st.—During the past week she has had severe pain in the abdomen, bowels loose, passing undigested food, and occasionally complaining of nausea. Her pulse has ranged from 120 to 130, temperature 100° to 101°, and respirations from 50 to 60. Fed her with peptonized milk, beef juice, and brandy. Her cough still continues loose, though there is occasionally a day when it seems tight.

5th.—During the past few days the area of dullness has increased; to-day made an exploratory puncture with a hypodermic syringe and found pus.

6th.—Assisted by Dr. B. F. Westbrook, after giving her chloroform, an incision was made between the seventh and eighth ribs a little posterior to the axillary line, when about a pint of pus drained away; a soft-rubber drainage-tube was inserted and the wound dressed with marine lint and absorbent cotton. The quantity of pus discharged for several days was sufficient to saturate the dressings. The wound was dressed daily. Notwithstanding the free drainage, her condition did not improve, her temperature keeping between 100° and 102°, pulse 120 to 130, and respirations from 50 to 60. Her stomach troub-

led her more now than at any time during her illness, and she had constant pain and frequent vomiting.

12th.—As pus was found last evening by means of a hypodermic syringe in the left pleural cavity, it was aspirated to-day and four ounces removed.

18th.—Since the aspiration on March 12th her condition has not changed; temperature fluctuating between 100° and 102°, pulse 120 to 130, and respirations 50 to 60. To-day the left pleural cavity was again aspirated, but only about two ounces of very thick pus were obtained, when the needle became plugged; it was removed and inserted in a new place, but with a negative result. During the past week the right pleural cavity has been washed out daily with a warm 1-to-5,000 bichloride solution; suppuration was very free and very offensive in odor.

27th.—To-day the left pleural cavity was again aspirated and six ounces of pus were taken away.

Her condition does not seem so good; she is weaker, and it is with difficulty she can be induced to take any nourishment; her pulse and temperature have kept about the same, but her respirations are accelerated, running from 60 to 70. Before the aspiration to-day had intended to do a pleurotomy, but her father would not consent.

April 12th.—For four or five days after the last aspiration her condition improved; her pulse and temperature became lower and her respirations less frequent; her appetite improved, and she had very little trouble with her stomach and bowels, but during the past week the unfavorable symptoms have returned; to-day she was aspirated for the fourth time and ten ounces of pus were removed.

19th.—She has not improved since the last aspiration, her pulse, temperature, and respirations still keeping very high. To-day she was aspirated for the fifth time, but only two ounces of pus were obtained.

May 6th.—As there has been no improvement, and as the left pleural cavity is evidently filling up, her father consented to have an operation done. So to-day, assisted by Dr. B. F. Westbrook, after giving her chloroform, an incision was made into the left pleural cavity and about eight ounces of thin, dark-colored, and foul-smelling pus were evacuated. A soft-rubber drainage-tube was inserted and a dressing of marine lint and absorbent cotton applied. There was considerable shock following the operation; she was put on an ounce of champagne every hour, which was retained after the second dose; after five or six hours the interval was increased to two hours. The next day she commenced to take a little peptonized milk.

The left pleural cavity was washed out daily with a 1-to-5,000 bichloride solution for four days, when her temperature came down to normal and remained there. From this time there was a steady improvement, though her pulse and respirations did not come down to normal for three or four weeks.

The tube was removed from the right side on June 8th, three months after the operation, and the sinus had closed ten days later.

On June 22d the tube was removed from the left side, seven weeks after the pleurotomy, and the sinus was closed in a week.

At this writing, three months after the second tube was removed, the child seems well. The percussion-note and auscultatory sounds are normal; her appetite is good and she has gained in weight.

Indubitably the second pleurotomy in this case should have been done at least a month earlier, but it was impossible to get the consent of her family.

How many times it is advisable to aspirate a pleural cavity containing pus before making an incision I can not say. There is nothing very formidable about the operation, and certainly in this case there was no benefit derived from aspiration.

THE TREATMENT OF INTERNAL HÆMORRHAGES.

By JOHN FERGUSON, M. A., M. D.,
L. R. C. P., L. F. P. S.,
DEMONSTRATOR OF ANATOMY, MEDICAL DEPARTMENT, UNIVERSITY OF TORONTO, AND LECTURER ON NERVOUS DISEASES IN THE SUMMER SESSION.

There are few more trying positions which the practitioner of medicine can find himself suddenly forced to occupy than that of facing a severe internal hæmorrhage—cerebral, pulmonary, gastric, intestinal, or uterine. At the lonely hour of midnight and far away from consultation he may be called upon to act; and it is well to have one's mind already made up as to the course that should be pursued in the various forms of hæmorrhages, for "to be forewarned is to be forearmed." It is with the view of summing up our knowledge on this subject, and with the hope of adding a few new points, that this contribution is offered to the medical profession.

In the first place, it is very apparent that the amount of blood that will flow through a rent in the wall of any vessel must be greatly influenced by the total amount of blood in the system and the amount of pressure upon the vessel from within. This being the case, the first step to take in dealing with a hæmorrhage is to cut off the supply of liquids. In this way the amount of blood is kept down, while it becomes thicker in quality and better fitted for the forming of a good, firm clot in the torn or ruptured vessel. Another step in the same direction is to reduce the volume of blood by actively eliminating water from the system. The hypodermic injection of pilocarpine rapidly unloads the body of water and inspissates the blood left behind, lessening thereby the freeness of the flow. This would not, however, be suitable in cases of pulmonary bleeding. Other diaphoretics might be selected, according to the judgment of the physician, or the nature of the case and the condition of the patient.

Another group of remedies is of much value in dealing with such cases. Those purgatives that produce copious watery stools, and at the same time are not irritating or depressing, must be placed high on the list of things we may use for the relief of the sufferer intrusted to our charge. Of these purgatives there is none so good as Epsom salts—the sulphate of magnesium. When given in saturated solution, without water, in free doses, and oft repeated, very free watery evacuations are produced, the amount of fluid in the vascular system is speedily lessened, and the hæmorrhage to this extent controlled. By maintaining this action for some time, the ruptured vessel has time to heal, because the pressure is largely taken off it, and it is put into the condition of rest. In addition to this, however, the blood is thickened. In some cases of cholera—sporadic or epidemic—where the rice-water stools have been very abundant, the blood becomes so reduced in volume and so inspissated as not to flow from a wound made in a large vein. In the event of the hæmorrhage being due to the ulceration of typhoid fever, this plan could not be had recourse to,

although I have used it with advantage in the bleeding of gastric ulcer. In the hæmorrhage, often so free, from soft and rapidly growing uterine fibroids, it is specially useful, if continued long enough—say for months.

Some persons have a strong tendency to bleed, and any hæmorrhage is hard to stay. The mucous membranes of the nose, stomach, bowels, or bronchial tubes ooze away, and though the flow may not be very rapid at any one time, the total amount lost is very considerable. I once saw a girl of thirteen brought almost to death's door by such a hæmorrhage from the mucous membrane of her lip. In purpura we know how readily patients suffer from subcutaneous extravasations. For this form of slow, continuous oozing the following formula may be found highly serviceable: Mix one ounce each of absolute alcohol and oil of turpentine in a glass or Wedgwood mortar. To this add very slowly, stirring all the while, one ounce of sulphuric acid. When all chemical action is over, the mixture may be bottled. Of this, ten or fifteen minims may be ordered every two, three, or four hours as needed. I have found these "black drops" of very great value in some exceedingly troublesome cases.

In the event of a very severe post-partum hæmorrhage the medical attendant may try ergotine hypodermically, or hot vaginal or rectal injections; but these may fail. It is a belief, not yet quite dead, that the uterine sinuses are closed by clots. This is quite erroneous. The uterine vessels and sinuses are interlaced by muscular fibers, and it is the contraction of these that arrests the hæmorrhage. This muscular tissue, as it were, ligates the vessels that would bleed; and so long as the contraction is good there is no danger. Now, for the maintenance of this tonic action of the muscular tissue in the uterus I have found the application of heat to the lumbar portion of the spine very useful. It stimulates this portion of the nervous system by bringing more blood to it. There is a greater influx of nerve energy to the uterus and contraction is brought about. It is true that the uterus seems to be very independent of the spinal cord, and labor may take place in a paraplegic. This does not, however, invalidate the fact that heat—applied to the spine by a large sponge dipped into hot water—does much good in the way of rousing the uterus to action. But when all things fail, as fail they will at times; when ergotine, acetate of lead in large doses, hot injections, and heat to the spine disappoint us, we have one last resort: Tampon the uterus and vagina thoroughly with iodoform gauze, or, if this is not at hand, some cloths to which glycerin is added. This plan I am quite sure will not fail. The bleeding is soon arrested, the uterus begins to contract, tone in its walls is secured, and one can feel at ease that the patient is out of all immediate danger.

As a means of arresting hæmorrhages and gaining time for other remedies, I would suggest the following plan, one great feature of which is that it is always available and does good. It is applicable to cases of capital operations on the body, such as the removal of large and vascular tumors from the neck, the female breast, etc. The plan is simply to tie bands around the legs and arms close up to the body. This arrests the return of blood to the body, while the flow of blood into the limbs still goes on. By this means a very large amount of the blood in the body is rapidly collected into the four extremities and the pressure taken off the central vessels. One day, when in my last year as a student, in 1879, I was walking along the streets, when I came upon an excited little crowd of people. I saw that one of the number, a young man of about thirty years, was bleeding freely from his lungs. I had nothing with me, but had just been thinking about venesection and the swollen condition of the veins in the arm. I seized the present opportunity, tore up a handkerchief, and tied the strips very firmly around the four extremities. The results were very gratifying. Ever since I have made extensive use of these bands, and now feel a good deal of confidence in recommending them to others.

I have already mentioned the usefulness of the hot sponge to the lumbar region in post-partum hæmorrhage. Now, in other cases of internal hæmorrhage—as from the mucous membranes of the stomach, nose, and bowels—the spinal ice bag is no mean therapeutic agent. It induces anæmia of the spinal cord and a marked dilatation of the surface blood-vessels. The internal strain is reduced, and consequently the hæmorrhage lessens.

A CASE OF TRAUMATIC NEURITIS

ILLUSTRATING THE MEDICO-LEGAL VALUE OF ELECTRICITY IN DIAGNOSIS.

By WILLIAM BROADDUS PRITCHARD, M. D.,
LECTURER ON MENTAL AND NERVOUS DISEASES, NEW YORK POLYCLINIC.

The statement was recently made in the presence of the writer that the number of civil suits for damages for injury received through accident or carelessness averaged, in the courts of the cities of New York and Brooklyn alone, as many as five hundred weekly. The additional statement was made that at least one third of these cases were fraudulent, the trivial character of the injury received, or some other factor, entitling the plaintiff to neither damages nor commiseration. The important point in such cases is the difficulty in discriminating between the honest suitor and the malingerer. With a skilled expert this is ordinarily not a troublesome task. It should be remembered, however, that, in the majority of instances, these suits are for small amounts, and the insignificance of the sum at stake does not justify the employment of an expensive specialist. The only medical testimony introduced in such cases is that of the attendant physician, who is usually a general practitioner, and, by reason of that fact, not competent to express an expert opinion. In many instances the injury is of such a gross and palpable character that the simple appearance of the plaintiff in court is all that is necessary to convince both judge and jury of the justice of his claim. Such cases rarely come to trial, however, for the defendant recognizes the strength of the suitor's position and his own consequent weakness, and the case is settled out of court. Very serious injury may have occurred, however, and of a permanent character, of which there may be no evidence superficially, or even upon fairly close examination, except the sensations of the patient. The pa-

tient's statements, when he is also plaintiff and a money issue is at stake, are notoriously unreliable. The most striking and conspicuous illustration of the difficulties encountered in adjusting such cases upon a basis of merit is to be met with in the numerous suits in which the plaintiff's injury is that of so-called spinal concussion. The medico-legal literature of the subject alone represents an expenditure of money which would afford a generous income for life to every honest victim of this injury. There is another class of cases which bids fair to rival the now famous "railway spine" in the obscurity which often surrounds a correct diagnosis and a consequent correct estimate of the amount of damage incurred. For this new class of cases we are indebted to the investigations of the neurologists, who have added to the nosology of medicine a comparatively new and distinct entity in disease in neuritis, or inflammation of a nerve. While it is true that nerve inflammation, from injury or other cause, has been for many years recognized pathologically and, to a certain extent, symptomatically, it is only within the recent past that the symptomatology and clinical diagnosis have been accurately understood, or the disease classified as a distinct affection in text-books upon medicine. Even to-day, full as is our knowledge of the subject, cases are not infrequently encountered in which the absence of objective symptoms renders a diagnosis a matter of much obscurity and doubt. Such a case recently occurred in the practice of the writer, and is taken as the occasion for this paper. The history is as follows:

On November 6, 1889, I was called to see B., aged fifty-nine, a janitor by occupation. I found him suffering from an injury to the right shoulder, said to have been received two days previously, caused by a fall through an open coal hole in the sidewalk. Upon removing the bandages and dressings, which had been applied at the hospital immediately after the receipt of the injury, I found his shoulder very much swollen and discolored from bruises involving the outer aspect of the shoulder and upper arm, the region occupied principally by the deltoid group of muscles. Careful examination showed no evidence of fracture or dislocation, though there was considerable interference with motion from soreness and swelling, especially in abduction. The swelling was sufficient to produce a difference of an inch and an eighth in the circumference of the two shoulders, as shown by measurement. The patient freely announced his intention of bringing suit for damages, and insisted upon a careful and accurate examination of his condition, which, however, revealed nothing beyond the symptoms detailed above. The swelling and inflammation gradually disappeared under treatment, and the interference with motion became less. On December 23, 1889, nearly eight weeks after the injury was received, the patient called at my office complaining of continued pain and a loss of power in the arm affected. I had not seen him for nearly two weeks previously. The pain, he stated, was confined to the outer aspect of the shoulder. Upon examination, I found no special painful spot, but tenderness on pressure and pain on motion in areas supplied by the supra-acromial branch of the cervical plexus and the circumflex nerves. The swelling had disappeared entirely, and motion in every direction was normal, except that elevation of the arm at the shoulder was done quite slowly on account of the pain produced in the attempt. There existed a state of cutaneous hyperæsthesia and a subjective sensation of numbness in the part affected. Measurement of the two arms showed no special wasting or atrophy. The right-hand grasp was slightly diminished. Pain, tactile and muscular sense were normal in the forearm and hand. A mild current from the secondary coil of a faradaic battery gave a painful, irritable response. To the galvanic current the response was at that time normal. Although neuritis was suspected, a diagnosis could not at that time be made which would conform to the requirements of a medico-legal standard. The patient's condition remained practically unchanged up to May, 1890, the pain and weakness varying in intensity and degree, the periods of temporary amelioration corresponding to treatment by electricity, which was kept up, though with great irregularity and at infrequent intervals. Examination on May 2d showed slight atrophy, which, however, might have been (apparently) due to non use. Pain was still complained of, and the loss of power had increased, as shown by the patient's greater helplessness and the dynamometer, neither test, however, being absolutely reliable. The hyperæsthesia had disappeared, though the subjective sensation of numbness still remained. I failed to demonstrate absolute loss or very marked diminution of either tactile or pain sense in the upper arm and shoulder. Muscular sense, on account of the difficulty of testing it in this locality, I did not investigate. So far my diagnosis of traumatic neuritis, while more plausible, was not established, but, upon testing the circumflex nerve by the galvanic current, all doubt was at once dispelled, the reaction showing a reversal of the normal polar formula of Erb—an indication of degeneration.

A brief *résumé* of the history and circumstances of the case will bring out the more clearly the points which it is intended to illustrate. A man received an injury under circumstances which gave him good grounds for a suit for damages. Carelessness on the part of the defendant could be easily established and was practically not denied. The extent and permanency of the injury received, by which the amount sued for was to be regulated, was the only point at issue. It can readily be seen that here was a strong motive for exaggeration, in both particulars, in a man whose social sphere and surroundings were such as to almost preclude the possibility of any extraordinary sense of moral or ethical responsibility. There was little tangible evidence of serious injury for a long time. The arm, after the swelling disappeared, looked like its fellow, and the symptoms of pain and loss of power might have been readily assumed. Such, at any rate, was the plea of the defense, and upon it they expected to either defeat the plaintiff outright, or so far to reduce the amount of damages awarded as practically to win in any event. On the other hand, the plaintiff's case was a just one; he had been seriously and more or less permanently injured (for the prognosis is not extraordinarily good in such cases and never certain), but how was he to prove it? His personal statement, that of the interested party, was almost the only evidence to support his claim. The physician might have testified as to a probable diagnosis, but, until after the demonstration by the galvanic current of a degeneration in the nerve, his evidence would have been problematical and necessarily uncertain in its effect. This demonstration, however, altered the whole aspect of the case. Becoming satisfied of its correctness, the attorneys for the defense, foreseeing defeat, would not allow the case to come to trial, but paid over at once almost the full amount claimed as damages.

My object in reporting this case is to illustrate the value of electricity as a means of diagnosis, already firmly established, in diseases of the nervous system. In this particular instance it transformed a prospective failure into an absolute success, it proved an invaluable aid to the administration of justice, and it lifted the black shadow of suspicion from an honest man.

Correspondence.

LETTER FROM LONDON.

Post-graduate Instruction in London.—The University of London Scheme.—The Commencement of the Winter Session.—The Clinical Society.—A New Dictionary of Practical Medicine.

London, *October 11, 1890.*

The third session of the London post-graduate course is about to begin, and the present time may therefore seem not inopportune to review its working and success so far. It was framed originally with the intention of affording to practitioners in our own country or to those from foreign parts an opportunity of brushing up their knowledge and becoming familiarized with modern methods of diagnosis and treatment, and for this purpose our leading special hospitals united to give a combined programme of clinical lectures and demonstrations. Five hospitals originally took part in it, representing diseases of the chest, of the nervous system, of the eye, of the skin, and of children; and subsequently arrangements were made whereby the patients at one asylum for the insane and one poor-law infirmary were made available for the purposes of the class. The hospitals that joined in the scheme were the best known in their respective branches. The lectures and demonstrations were so arranged as not to clash with each other, and yet so that the members of the class should have their time fairly well occupied, and the fee for the course was ridiculously small. Moreover, it was permitted to any one to join for only certain portions of the course if he wished to do so and pay a proportionate part of the fee. Notwithstanding all the advantages which the scheme appeared to offer, the number of entries was absurdly small, and the second course did not meet with more success than the first in point of numbers, and, if this third course does not attract students in greater numbers, the scheme will almost inevitably die a natural death. The lecturers and teachers engaged in it are almost without exception men who hold appointments at the general hospitals, with plenty of teaching to do at their own schools, and it can not be expected that they will continue to take part in this post-graduate teaching unless there is much better evidence than has hitherto been supplied that their efforts are appreciated. It is my firm belief that the great majority of English, Scottish, Canadian, and American practitioners, who every year spend a lot of time and money in Paris, Berlin, or Vienna, would do far better if they spent the time in studying at the special hospitals of London.

In my last letter, I believe, I referred to the University of London scheme as on the point of being satisfactorily arranged. I was a little too premature in doing so, for at the last minute the senate of that body found themselves quite unable to reconcile the conflicting views pressed upon them from all sides, and gave up the task in despair. Such a contingency had been foreseen, but it is one thing to be able to foresee what may happen and quite another to be able to prevent it. What will probably happen now is that the commissioners who were formerly appointed to consider this subject, and by whose advice the existing university was requested to undertake the settlement of the questions, will be called upon to resume their labors, and that they will frame a scheme which the Government will endeavor to carry into effect, whether the existing bodies like it or no. In their former report the commissioners were divided as to whether a new university should be founded or not. It is tolerably certain that a new university is inevitable now, a fact which I think the great majority of those who have followed the question have long since realized.

Another winter session has begun, with its usual complement of introductory addresses and old students' dinners, and the chief topic at present is as to the relative number of entries at the different schools. I suppose they will be published next week. At present I have no very reliable information to give on the subject, but I should not be surprised if this year and next the entries were unusually good, for in 1892 the new regulation will come into force requiring a five-year curriculum instead of four, and that will presumably mean an increase of fees—a fact to which parents and guardians will be fully alive.

The Clinical Society is the first to get under way this year. It held its first meeting yesterday evening. It is also the first in the field with its annual volume of *Transactions*, which was distributed to the members a few days ago. The volume is quite up to the average of its predecessors, the majority of the papers, as usual, being surgical. Perhaps the first is as valuable as any. It is by Mr. Mayo Robson, and refers to a series of fourteen cases of cholecystotomy.

The only book that has come out lately of any importance is a *Dictionary of Practical Medicine*, published by Messrs. Churchill and edited by Dr. Kingston Fowler. It is of convenient size, and those who like having their subjects condensed for them ought to be pleased with it, for the writers include all the best men of the rising generation of physicians. The articles are short and to the point, and, for the most part at any rate, do not waste the reader's time with long dissertations upon theoretical points. The book has come out none too soon, for Quain's *Dictionary* is undergoing revision, and will be a formidable antagonist for its younger rival.

Two well-known names have been added to our death roll during the last few weeks. Handfield Jones has passed away in the fullness of years after a long and active career as a clinician and pathologist. A stupendous worker, he never became widely known, but at his own hospital (St. Mary's) he was greatly respected. Dr. Matthews Duncan, on the other hand, was of world-wide renown, and as a clinical teacher and lecturer had few if any superiors, certainly none in his own line. He will long be missed at St. Bartholomew's Hospital, where his lectures were immensely appreciated.

The Mortality of Widowers from Phthisis.—"In a paper on Tuberculosis in Belgium MM. Destrée and Gallmaerts come to the conclusion as the result of their investigations that, in comparing the mortality from phthisis of bachelors, married men, and widowers, the last are very much more subject to this disease than either of the other classes. The same statement holds good for all ages, and it is, they say, also true that widows are more liable than single women to die of phthisis. The authors do not think this is to be explained except by direct contagion of wife to husband or husband to wife. They can not think irregularities and excesses indulged in by widowers can be answerable for it, for advanced age does not seem to make any difference. They would ascribe it to infection occurring during married life, the disease claiming its second victim some time after the death of the first."—*Lancet.*

THE

NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Edited by Frank P. Foster, M. D.

NEW YORK, SATURDAY, NOVEMBER 1, 1890.

ACUTE PLEURISY AND ACUTE RHEUMATISM.

In 1883 Aufrecht drew attention to the decided results he had obtained in the treatment of acute pleurisy with the salicylates. Recent writers, notably Tetz (in the *Therapeutische Monatshefte*, No. 7, 1890), have confirmed his observations. We must allow that the title of a remedy to cure acute pleurisy must be very well substantiated. Acute pleurisies have a way of stopping short without treatment, of beginning with a fierce pain which suddenly abates, and of suddenly going on into the stage of extensive effusion with very little warning pain at all. Nevertheless, the successful results of the administration of salicylates in acute pleurisy, as recorded by these writers, are sufficient to raise in our minds the question as to whether acute rheumatism and acute pleurisy are not the same disease. Long ago Mr. Hilton, in his admirable lectures on *Rest and Pain*, pointed out the resemblance between the pleura and pericardium and the joints. The pleural cavity represents a huge joint constantly in motion. It has the two surfaces covered by serous membrane and gliding smoothly upon each other by the aid of a lubricating fluid. And Mr. Hilton went on to apply his law of associated muscular action, nerve supply, and function to the pleura, showing how, when inflammation took place, the nerves of the pleura that were directly in communication with those supplying the intercostal muscles called for cessation of movement, and how the pain felt in the skin over the inflamed area was the agent by which this needed rest was obtained. Practically the same thing occurs in the joint that is inflamed and painful from acute rheumatism. Probably the resemblance between inflammation of a serous membrane and that of a joint would be more striking were the conditions exactly similar. But in the case of the serous membrane complete rest of the opposed surfaces can not be obtained. The lungs can not cease taking in air, and the heart can not stop beating. Probably this accounts for the more fibrinous and adhesive character of the effusion, a further effort of Nature to secure rest. In the case of the joint immediate rest is secured, and the effusion is not adhesive in ordinary cases.

The clinical features of acute rheumatism point to a common origin with pleurisy, if not to a practical identity. Many cases of acute articular rheumatism are complicated with effusion into the serous membranes. We say *complicated*, but we mean really that the pleural joint or the pericardial joint has been attacked as well as the wrist joint or the elbow joint. And pleural effusions are of much more frequent occurrence in the course of rheumatism than is commonly supposed. In the ordinary run of cases of acute rheumatism the joints are so very painful that an examination of the bases of the lungs is not quite practicable, and, moreover, there are many practitioners who do not injure themselves with overzeal in the clinical examination of patients, particularly after a good working diagnosis has once been made out. We are satisfied that, if pleural effusions in rheumatism were more frequently looked for, they would be oftener found, and those who found them would be more disposed to regard rheumatism as a general attack on all the joints, including the serous membranes.

The general tendency to look with suspicion upon "exposure to cold" as a cause for so many diseases, to regard chilliness as an effect consequent upon the poisoning of the system by some external agent, rather than as a cause of disease, makes us skeptical as to whether such a thing as *pleuritis a frigore* exists. Is it not more rational to regard it as being due to some inherent tendency in the individual to inflammations of an arthritic form, and to infer that, when pleurisy occurs alone, it simply means that only one joint is affected, or perhaps that the main attack has been upon one joint, the others escaping lightly? The frequent occurrence of pleurisy without effusion into other joint cavities might arise from the fact that into the pleura a quantity of fluid may be effused rapidly, while when the joints are the main point of attack but little can make its way into them. To borrow an old expression, the *materies morbi* readily leaves the blood to fill up the pleural cavity, but, attempting to pour itself into a joint, it meets with resistance and seeks an outlet elsewhere. The effect of the salicylates, so well marked in rheumatism, ought to be equally good in this disease, and we trust that many observations will be made in this interesting subject.

FAULTY METHODS OF SINGING.

Physicians have from time to time called attention to the injurious effects of faulty methods in the use of the singing voice. We do not recall, however, so pointed and convincing an argument against the practice of forcing the tongue to lie flat on the floor of the mouth while singing as is contained in Dr. Langmaid's article, published in this issue of the Journal. That the author speaks with the authority of one well versed in vocal physiology, and having had abundant opportunities for observing the actual relationship of cause and effect between certain styles of vocal exertion and the physical impairments that he attributes to them, everybody conversant with what has been going on in laryngology in this country for a number of years past is fully aware; but it seems from his article that, in addition, he speaks with no little knowledge of the real requirements of the art of singing. Even were all this not the case, however, the presumption in this matter would be altogether in favor of his contention, for attempts to trammel an organ in the performance of any of its functions seldom if ever accomplish anything that can be called advantageous, all things considered, and almost as rarely anything desirable considered by itself. Forced depression of the tongue in singing probably increases the reverberation that takes place within the cavity of the mouth and swells the volume of sound, but mere quan-

tity of clang is a small factor in vocal music, and, if it were the chief factor, it might perhaps be obtained by devices that, however grotesque they might seem, would not interfere with the play of any of the parts concerned in phonation and articulation.

We do not know how general the practice of forcing the tongue down is among singers, or what proportion of those who resort to it escape the serious disability that was observed in Dr. Langmaid's cases; but it is evident that there is a good deal of defective enunciation among public singers, and it seems reasonable to suppose that it may be due in great measure to the practice in question. The tongue is not absolutely essential to intelligible articulation, as is shown in persons who have had the misfortune to have the member excised; but its importance to that function is unquestionable. Vocal music is defective so long as the words are not distinctly uttered, no matter what the excellence of phonation may be. Probably the best results as regards both elements are to be attained, other things being equal, only when the composer is his own librettist, for it is well known that certain notes are easier of production with some vowel sounds than with others. If the proper conformity of words to notes were always maintained, perhaps such devices as restraining the tongue in singing might be resorted to with an approach to impunity, for possibly it is the tax they impose on articulation rather than on phonation that proves injurious. Until it is shown, however, that this is the case, vocalists will show their prudence by avoiding them.

MINOR PARAGRAPHS.

THE SLEEPING SICKNESS OF AFRICA.

At the Harley House, London, there is a young man, a native of the Congo River valley, who has journeyed to England for the purposes of an autopsy. He believes himself to be in the incipient stage of the mysterious and incurable disease known as the sleeping sickness, and he has left his wife and children to place himself and his body, after death, at the disposal of the medical men, in order that they may so study his case as to ascertain the cause, morbid changes, and means of relief of this comparatively unknown malady. The young man's name is Mandombi, and he is a member of the missionary church at the Banza Manteka station, where not fewer than sixty of his fellow-converts have been carried off by the sleeping sickness. His own sister is dying by it; she becomes almost maniacal at the full of the moon. His brother, by marriage, died by it at about the time of his departure, which was a spontaneous action on his part, in order that by dying in a foreign land he might perchance benefit his yet unafflicted countrymen. Mandombi is yet well and able to work, but he is smitten with the trouble, as is shown to others by some little impairment of his mental alertness. The disease is not believed to be contagious, although several members of the same family may die by it. So far as the observation of the missionaries goes, no case has been saved from a fatal termination by treatment. The duration may extend for three years, or it may be only two or three weeks. As the disease progresses the patient is said to sleep his life away, although in severe cases maniacal symptoms develop. Great emaciation marks the chronic cases. "Nelavan" is a term used by Déclat and some other French writers as descriptive of the sleep disease of Africa at some points to the north of the Congo, but on the west coast, where it appears to be endemic, Déclat thinks he has found some points of resemblance between nelavan and the chicken-cholera. Mr. Stanley makes no reference in his last volumes to the occurrence of the disease among his carriers, not a few of whom were probably taken from the lower Congo districts, where the disease is most frequent.

THE SEXUAL PERVERSION OF HAIR-CUTTING.

Dr. A. Motet, the well-known alienist, has reported to the *Société de médecine légale*, as recorded in *Le Progrès médical*, a case of unusual sexual perversion. A young man was arrested for attempting to cut off a young woman's hair. The police were led to make a search of the rooms occupied by the accused, and there found a considerable quantity of hair, the motive for the cutting off of which had been sexual and not mercenary in origin. It was subsequent to an attack of herpes intercostalis in 1886 that his erratic behavior began; he then for the first time began to have the imperative propensity to cut off women's hair. So soon as the shears would touch the hair he had an erection, and the cutting off was followed by an ejaculation. It was found that his parents, on both sides, had transmitted to him a marked neurotic tendency, but this had not prevented his acquiring his trade and becoming a skillful and intelligent artisan. He was adjudged insane and confined for a time in an asylum. He recovered under treatment and was set free from his peculiar perversion. He was enabled afterward to resume work at his trade.

ANÆSTHESIA BY HYPNOTISM.

According to the *British Medical Journal*, Dr. Schmelz, of Nice, recently removed a sarcomatous breast from a girl, aged twenty years, during anæsthesia produced by hypnotism. The entire breast, with the aponeurosis of the pectoralis major muscle, was removed by the usual oval incision, drainage-tubes were inserted, and the wound was closed with thirty-two metallic sutures. The operation lasted an hour, the patient remaining in a state of anæsthesia during the entire period, though she encouraged the operator by her words, laughed, and was quite gay. The only symptom noticeable during the operation was great pallor of the countenance, but there was no dilatation of the pupil or weakening of the pulse. She had no pain after the operation, and the wound healed on the fifteenth day.

A SLUR ON THE POLYCLINIC CORRECTED.

The statement having been made in one of the New York newspapers that a young Alabama clergyman had "died from the effect of an operation performed in the New York Polyclinic eight months since and pronounced at the time 'highly successful,'" the father of the deceased, also a clergyman, has had the manliness to write to the editor of the newspaper assuring him that the operation was indeed completely successful, and that his son's death could in no way be attributed to it.

THE SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

The meeting to be held shortly in Atlanta will undoubtedly be one of great interest and profit to the members of the association. This is to be inferred from the programme, which we have already published, as well as from the character of the past meetings. The association must be set down as one of exceptional vigor. It includes most of the leading surgeons and gynæcologists of the South, and is evidently well managed.

THE PUBLIC SCHOOLS OF NEW YORK.

Much has been said from time to time about the bad sanitary state of some of the public-school buildings of New York, but little impression seems to have been made on those who are charged with their supervision. Last Monday evening, however, the committee on hygiene of the Medical Society of the County of New York made a report setting forth the defects of certain of the buildings most pointedly, and this report, having been summarized in some of the newspapers, seems likely to prove more effective.

DEATH FROM FOOTBALL INJURIES.

A fatal casualty is reported by the *Lancet* resulting from a football match. A young man came into collision with another player and was injured in the groin on Saturday, September 20th. On Monday he was dead, although meanwhile an operation had been attempted for his relief.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 28, 1890:

DISEASES.	Week ending Oct. 21.		Week ending Oct. 28.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	44	9	37	7
Scarlet fever	25	1	42	1
Cerebro-spinal meningitis	0	0	0	0
Measles	52	5	82	6
Diphtheria	57	17	67	21
Small-pox	1	0	0	0
Varicella	2	0	1	0

The Johns Hopkins University.—It is announced that a committee of ladies who had resolved to raise the sum of $100,000 for founding a medical college to which women would be admitted has succeeded in its object, and that the trustees of the Johns Hopkins University have accepted the fund in accordance with the following terms, stated in a communication to them from Mrs. Davis:

"The committees formed for the purpose of raising a fund to procure the most advanced medical education for women can now place at your disposal the sum of $100,000 for the use of our medical school, if you will by resolution agree that women whose previous training has been equivalent to your preliminary medical course shall be admitted to the school, when it shall open, upon the same terms which may be prescribed for men. There is little doubt that a sufficient number of women ought to be educated and trained in such manner as to be fully able to care for sick women who may wish or ought to be treated by women. We have devoted ourselves to the furtherance of this object. We have reason to hope that a university which proposes to found a medical school intended to teach advanced methods in the treatment of those diseases which afflict mankind will not refuse to women the opportunity of learning such methods. There is now a general interest in our movement. In order that this interest may be sustained, we ask you to consider our offer at the earliest possible moment."

The Medical Society of the County of New York.—At the annual meeting, held on Monday evening, the 27th inst., officers for the ensuing year were elected as follows: President, Dr. Orlando B. Douglas; vice-president, Dr. Arthur M. Jacobus; secretary, Dr. Charles H. Avery; assistant secretary, Dr. William E. Bullard; treasurer, Dr. John S. Warren; and censors, Dr. George E. Abbott, Dr. S. O. Van der Poel, Dr. Alexander S. Hunter, Dr. William M. McLaury, and Dr. Richard Van Santvoord.

The Mount Sinai Hospital Alumni Association.—At a meeting held at the hospital on Tuesday evening, the 28th inst., Dr. Abraham Jacobi read a paper on Some Points in the Pathology and Therapeutics of the Genito-urinary Organs, and Dr. Charles H. May read one on The Early Eye Symptoms of Chronic Alcoholism.

Changes of Address.—Dr. Augustin M. Fernandez, to No. 209 West Tenth Street; Dr. Maurice L. Healey, to No. 220 East Thirty-sixth Street; Dr. Elizabeth Johnson, to No. 68 West Thirty-eighth Street; Dr. M. R. Richards, to No. 77 East One Hundred and Sixteenth Street; Dr. Edward F. Schwedler, to No. 43 East Fifty-ninth Street; Dr. Winslow W. Skinner, to the Adirondack Cottage Sanitarium, Saranac Lake, N. Y.; Dr. J. E. Welliver, from Rushville, Ind., to the northeast corner of Second and Ludlow Streets, Dayton, O.

The Death of Dr. George T. Foster, of Pittsfield, Mass., occurred on October 22d, of gastro-enteritis. He was born in Lyndon, Vt., in 1810, and graduated from the Albany Medical College in the class of 1847. He began practice in Windsor, Mass. He remained there but a short time, when he removed to Chatham, N. Y., where he practiced for a number of years. Finally his health failed and he again removed to Pittsfield, where he afterward resided. For over twenty years his health did not permit him to engage in active practice, but he was well and favorably known in the vicinity as a consultant. He is survived by his son, Dr. M. L. Foster, of New York.

The Death of Dr. Justus E. Gregory, of Brooklyn, occurred suddenly on October 26th, while he was absent from his home. He was a great sufferer from neuralgia, and occasionally obtained from chloroform inhalation a sufficient relief to enable him to complete his round of visits. On Sunday last he had recourse to this treatment while resting in an apothecary's shop not far from his office, but death ensued suddenly. He was an expert, in the minds of his professional neighbors, in the administration of anæsthetics. He was a native of Troy, and an alumnus of the Albany Medical College.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 19 to October 25, 1890:*

Glennan, J. D., First Lieutenant and Assistant Surgeon, is granted leave of absence for one month, to take effect about the 31st instant. Par. 1, S. O. 146, Department of the Missouri, October 23, 1890.

Jarvis, N. S., Assistant Surgeon, is granted leave of absence for one month on surgeon's certificate of disability. S. O. 107, Department of Arizona, October 14, 1890.

Pilcher, James E., Captain and Assistant Surgeon, is granted leave of absence for four months, by direction of the Secretary of War. Par. 12, S. O. 244, A. G. O., October 18, 1890.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending October 25, 1890:*

Cordeiro, F. J. B., Passed Assistant Surgeon. Detached from U. S. Steamer Nipsic and granted three months' leave of absence.

Heffenger, A. C., Passed Assistant Surgeon. Placed on the Retired List, October 20, 1890.

Society Meetings for the Coming Week:

Monday, *November 3d:* New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society (private); Brooklyn Anatomical and Surgical Society (private); Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vt., Medical Association; Providence, R. I., Medical Association; Hartford, Conn., City Medical Association; Chicago Medical Society.

Tuesday, *November 4th:* New York Obstetrical Society (private); New York Neurological Society; Elmira Academy of Medicine; Buffalo Medical and Surgical Association; Ogdensburgh Medical Association; Hampden, Mass., District Medical Society (Springfield); Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Me., County Medical Association; Baltimore Academy of Medicine.

Wednesday, *November 5th:* Society of the Alumni of Bellevue Hospital; Harlem Medical Association of the City of New York; Medical Microscopical Society of Brooklyn; Medical Society of the County of

Richmond (Stapleton), N. Y.; Penobscot, Me., County Medical Society (Bangor); Bridgeport, Conn., Medical Association.

THURSDAY, *November 6th:* New York Academy of Medicine; Metropolitan Medical Society (private); Society of Physicians of the Village of Canandaigua; Medical Society of the County of Orleans (annual—Albion), N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington).

FRIDAY, *November 7th:* Practitioners' Society of New York (private); Baltimore Clinical Society.

SATURDAY, *November 8th:* Obstetrical Society of Boston (private).

Proceedings of Societies.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Sixteenth Annual Meeting, held in Louisville, October 8, 9, and 10, 1890.

The President, Dr. J. M. MATHEWS, of Louisville, in the Chair.

(*Concluded from page 469.*)

Coffee.—Dr. I. N. LOVE, of St. Louis, in a paper on this subject, said that his experience for five or six years past had been strongly in favor of taking a cup of strong, black coffee, without cream or sugar, between two glasses of hot water, before rising every morning—at least an hour before breakfast. The various secretions were stimulated, the nervous force was aroused, an hour later a hearty meal was enjoyed, and the day's labor was begun favorably, no matter how the duties of the day and night preceding might have drawn upon the system. Another cup at four in the afternoon was sufficient to sustain the energies for many hours. In this way the full effect was secured. If, along with this, the proper diet was taken at the proper times—and the ideal diet for those who make large drafts upon their nervous systems and expected to have them honored was hot milk—and at least eight hours of sleep were taken out of every twenty-four, one's capacity for work would be almost unlimited.

Mechanical Obstruction in Diseases of the Uterus.—Dr. GEORGE HULBERT, of St. Louis, read a paper on this subject. He submitted the following conclusions: 1. That in the natural order of things we find the uterus in form and structure endowed with a power and capacity for the performance of the function of menstruation far in excess of any legitimate demand, to the extent that with a quarter-inch diameter of the canal the excess equals 7724·8 times the demand, and with a one thirty-second-inch diameter the excess equals 120·7 times the requirement. 2. That in the pathological conditions considered essential for mechanical obstruction we find that the conservation of force is capable of regulating, and does so regulate, conditions that the capacity is not abolished, but persistent in an eminent degree, so that in the presence of the normal physiological energy the function is accomplished, save in one emergency, that of total annihilation of the normal state—namely, atresia. 3. That the phenomena considered as attendant and dependent upon mechanical obstruction are not due to the forcible expulsion of retained fluids through the uterine canal, but are resident and produced *within the tissues*, and are dependent upon *disturbed rhythm of physiological forces*, evolved through abnormal innervation, muscular action, and circulation. 4. That the demand upon the uterus for the passage of blood-clots, membranes, mucous plugs, uterine sounds, sponge tents, uterine dilators, etc., in order that the diagnosis of mechanical obstruction may be made, is not only vicious in the extreme, but irrational, illogical, and unscientific. 5. That the correct and rational interpretation of the testimony offered by symptomatology, pathology, and therapeutics removes mechanical obstruction from the domain of gynæcology as a demonstable fact, save in atresia uteri.

Professor Flint's Doctrine of the Self-limitation of Phthisis was the subject of a paper by Dr. WILLIAM PORTER, of St. Louis, in which he said that some time before his death Professor Flint had promulgated the doctrine of the self-limitation of phthisis, and presented it with all his well-known power and great ability to the profession. This very interesting proposition had been at the time the subject of free debate in various medical societies. Recent years had been full of the wonderful results of the study of pulmonary disease and bacteriological research, and the possibility of a positive diagnosis had overshadowed the equally interesting question of prognosis. After having carefully examined the facts cited in support of the proposition, Dr. Porter had no hesitation in asserting that he found no sufficient evidence to warrant us in accepting the statement that phthisis was self-limiting, or that the element of self-limitation had a decided influence upon the result in any given case. He did not mean that all patients with phthisis necessarily died from this disease, but he did mean that where phthisis was firmly established there was nothing in the nature of the disease itself that indicated in any stage a fixed boundary—a line of demarkation, as it were—but rather that all its tendencies were progressive and downward.

Cough; its Relation to Intra-nasal Disease.—Dr. A. B. THRASHER, of Cincinnati, read a paper on this subject. The cough due to nasal disease might sometimes be recognized by its metallic ring and the absence of expectoration. It could, as a rule, be provoked at will by touching the irritable spot in the nose with a probe. Dr. Thrasher recited three cases illustrative of nasal cough.

The Medical Student was the title of a public address by Dr. JOHN A. WYETH, of New York. The hall was literally packed with people, and many members of the association who had come to hear the lecture were turned away, the students of the Louisville University having taken possession of nearly all the seats, thus literally freezing the members out. The address was listened to very attentively, and Dr. Wyeth received applause several times during its delivery.

He said the first or preliminary stage of a medical student's life was his preparatory or academic life; the second, his medical-college life; the third, his post-graduate or practical life, and it lasted from the day he left his alma mater until usefulness ceased. In the acquirement of a practical training three ways were open, and in order of preference they were: 1. Service as an interne, preferably for a term of two years, in a general hospital. 2. Service in some post-graduate institution where all departments of practical medicine were taught by teachers specially trained in their respective branches. 3. Service as an assistant to one or more well-qualified practitioners in general medicine.

Gunshot Wound of the Intestine.—Dr. M. T. SCOTT, of Lexington, Ky., reported a case. (To be published.)

The Cranial Development of Criminals.—Dr. G. FRANK LYDSTON, of Chicago, exhibited the skulls of a number of the most notorious criminals of the world, and made some remarks with reference to their peculiarities, shape, size, etc.

Cases of Penetrating Stab Wounds of the Abdomen; Laparotomy; Results.—Dr. H. C. DALTON, of St. Louis, read a paper thus entitled, in which he reported six cases of laparotomy in which there was visceral injury. One of them had ended in death and five in recovery. He laid particular stress on the necessity of following the wounds to the bottom and

making ocular inspection of the same rather than trusting to the introduction of the finger. He deprecated depending implicitly on Senn's hydrogen-gas test, on account of its fallibility.

Wiring the Separated Symphysis Pubis, supplemented by a Novel Pelvic Clamp, was the title of a paper by Dr. W. P. King, of Kansas City. He reported a case of separation of the symphysis pubis, with fracture of the interposed fibro cartilage and fracture of the descending ramus of the pubes with deep lacerations of the surrounding soft parts, and spoke particularly of the methods resorted to in order to support the pelvis and re-enforce the stitches after the pubic bones had been wired together. The case suggested the following points: 1. The operation of wiring so completely coaptated the parts that it would seem that scarcely any other method of dealing with this condition could be equal to it. 2. The manner of applying the plaster-of-Paris support in the first place, with the use of the water-bag to make an arch under which to dress the wounded parts, was new and original so far as the author knew, and it was a method that might be adopted and easily practiced by any one who knew how to use plaster of Paris. 3. The steel hip clamp as a permanent support was also new, so far as he knew, and was a means that might be adopted with benefit in any case of fracture of the pelvis in which immobilization of the fractured part would contribute to the comfort of the patient and to the union of the fracture.

Inguinal Colotomy.—Dr. Archi Dixon, of Henderson, Ky., in a paper on this subject, said that colotomy had during the past decade met with much attention from the surgical world. As a measure intended to ward off imminent death, it was called for in all cases of obstruction in the colon, from whatever cause arising. For imperforate anus the operation held a special position. It was intended to prevent impending death, but it might or might not be a cure for the disease. In many cases it was the first step in the process of cure. In every infant born with an imperforate anus an operation of a local nature was first attempted; if this failed, colotomy by some method was performed to ward off death. Later on an attempt might be made to get the bowel to discharge through the anus. In a few words, it might be said that the indications to operate in any given case depended, in the first place, on the chance that the patient had of getting well without an operation; and, in the second place, on the degree of probability of success following the operation. To cases of acute obstruction in the sigmoid flexure or elsewhere there was practically but one termination—death. No case of volvulus, whether of the large or small intestine, had as yet been known to recover under treatment purely medicinal. Here, then, the indication was clear enough, as clear as the indication to tie a bleeding carotid—an operation. Dr. Dixon reported an interesting case, after which he dwelt upon the comparative merits of the two operations, inguinal and lumbar colotomy.

Hypnotism in its Relation to Surgery.—Dr. Emory Lamphear, of Kansas City, read a paper on this subject and reported cases. He reported a case of double talipes in which the subject had chronic Bright's disease, which contra-indicated the use of ether, and at the same time had an organic heart trouble, which prevented the safe use of chloroform. The patient wanted to be operated upon, and the author hesitated to give the ordinary anæsthetic, and so hypnotized him. This was the first séance, and, contrary to the generally accepted idea that at the first trial a sufficient degree of anæsthesia could not be produced to admit of an operation, he performed the operation for talipes, and the patient lay upon the table as fixed and immovable as a piece of marble during the whole procedure. Another case (reported by permission of Dr. Shaw, of St. Louis) was that of a patient suffering from Jacksonian epilepsy due to brain tumor. He was hypnotized and trephined, and made no manifestation of pain.

Certainty in the Diagnosis of Tuberculosis.—Dr. Theodore Potter, of Indianapolis, presented a paper in which he mentioned features of the disease that called in a peculiar way for early treatment. But this must depend upon early diagnosis. In spite of constant progress from the time of Laennec to that of Flint, there had been no one sign and no combination of signs that was absolute. There was always some uncertainty, especially in the early or unusual cases. But now, with the new light of the present added to the knowledge of the past, we were able to make the diagnosis in the great majority of cases not only early, but with absolute certainty.

The Hypodermic Use of Arsenic.—Dr. Harold N. Moyer, of Chicago, contributed a paper on this subject. He said the hypodermic use of Fowler's solution had been recommended by various writers, among others Hammond, who stated that the dose that could be administered in this way was much greater than could safely be administered by the mouth, he having given as high as fifty drops of Fowler's solution as an initial dose. Again, he had often carried the amount given by the mouth to the utmost bounds of prudence, till the eyes were puffed and vomiting was almost incessant, and then had continued the use of arsenic in larger doses by hypodermic injection, with the result of the cessation of all gastric symptoms and the cure of the disorder. In a case of chorea in a girl, the patient had been placed immediately upon the hypodermic use of arsenic, beginning with three minims of the five-per-cent. solution and increasing every second day until three weeks after beginning treatment she was receiving thirteen minims of the solution at each injection, with an amount of arsenic equivalent to about thirty-six minims of Fowler's solution. At the ninth injection she was discharged cured. In the case of a woman who presented herself at the clinic in Rush Medical College with an enormous lymphadenoma of the side of the neck, after a few deep injections into the glandular mass it began to diminish rapidly. When it had lessened one half, the patient ceased attending, and the further results could not be noted. Dr. Moyer's observation was in accord with that of numerous writers who had reported equally good results from the use of Fowler's solution in various forms of glandular enlargement passing under the terms lymphoma, lymphadenoma, and Hodgkin's disease. The action of arsenic given under the skin, if it had any virtue, must certainly be greater than when it was taken by the stomach. Thrown into the cellular tissue in the form of a feeble alkaline and readily soluble salt, it was at once absorbed by the blood and carried to all the tissues.

Perineal Cystotomy versus Suprapubic Cystotomy.—Dr. H. O. Walker, of Detroit, read a paper on this subject. (To be published.)

Two Cases of Tubal Pregnancy were reported by Dr. Edwin Walker, of Evansville, Ind. He thought that laparotomy was the safest procedure to adopt.

The Treatment of Organic Stricture of the Male Urethra.—Dr. Seaton Norman, of Evansville, Ind., contributed a paper thus entitled, in which he said that in the practice of urethral surgery the operator could not be too emphatically impressed with the fact of the exquisite tenderness and sensitiveness of the urethra, and the employment of the slightest amount of force in the introduction of an instrument should be regarded as a relic of barbaric surgery. When commencing the treatment by gradual dilatation in sensitive patients, he always produced local anæsthesia by the injection of twenty to thirty minims of a four-per-cent. solution of hydrochloride of cocaine. Relative to internal urethrotomy, he believed that when it was properly and thoroughly executed, and special care was exer-

cised to maintain the patency of the canal until the wound was entirely healed, recontraction was of rare occurrence. Authority was divided in regard to the performance of internal urethrotomy in the bulbous and membranous urethra. Judging from the results obtained by Harrison, the combination of external and internal urethrotomy offered encouragement for the permanent cure of stricture. Dr. Norman had performed external urethrotomy without a guide only three times, and his results as regarded the non-recurrence of contraction had been entirely satisfactory. Of the various scales that had been proposed for urethral instruments, only the French, in his opinion, was worthy of consideration. To have urethrotomes graduated in millimetres—and all with which the author was familiar were so manufactured—and the sounds corresponding to the English or any other scale, was a manifest absurdity.

The Application of Antiseptic Methods in Midwifery Practice.—Dr. L. S. McMurtry, of Louisville, Ky., made some impromptu remarks on this subject. He said many medical practitioners could remember the time when they had heard that the wards of certain hospitals were closed and undergoing renovation because puerperal fever had become epidemic in such institutions. The hospital to-day was the safest place in which a woman could be confined. A few years ago, led by Fordyce Barker, we had been taught that puerperal fever was an entity, a distinct fever, dependent upon a separate materies morbi, just as malarial fever was an entity. To-day we knew that puerperal fever so called was a septic peritonitis, just as when a woman became infected after abdominal section or after wounds of the peritonæum from any cause, or from infection of the endometrium and, through the Fallopian tubes, of the peritonæum. A woman after labor was a wounded woman. She had undergone certain physiological processes; she had received certain injuries in the process of labor which opened the lymphatic channels by which she might have become infected from without. There was no such thing as a woman having a peritonitis unless she was infected from without. To prevent this infection, the vagina must be sterilized, the bed surgically clean, the examining finger clean, the nurse clean, and the atmosphere as approximately aseptic as it was possible to make it, etc.

Officers for the ensuing year were elected as follows: President, Dr. C. H. Hughes, of St. Louis; vice-presidents, Dr. John H. Hollister, of Chicago, and Dr. S. S. Thorn, of Toledo; secretary, Dr. E. S. McKee, of Cincinnati. It was voted to hold the next meeting in St. Louis, beginning on the third Wednesday in October, 1891.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN PÆDIATRICS.

Meeting of October 10, 1890.

Dr. L. Emmett Holt in the Chair.

Stricture of the Rectum following an Operation for Imperforate Anus.—Dr. H. D. Chapin presented an infant, thirteen months of age, which he stated had been discovered at birth to have imperforate anus. It had been operated upon by simple incision at once. Since that time the child had suffered from chronic constipation, and when brought to the hospital was in bad condition, having had no passage from its bowels for several days. A very tight stricture was found to exist just within the anus. An enema was given of ox-gall and glycerin, and a free evacuation resulted. This treatment was repeated daily. Examination revealed a large concretion of fæcal material just above the stricture. During the last twenty-four hours the child had had diarrhœa. A catheter had been passed some ten inches into the bowel, and a partially successful attempt made to break up the hard mass. He had brought the case before the Section with a view to gleaning what had better be done. His own feeling would be to put in something and divulse the stricture.

Dr. C. B. Kelsey called attention to the fact that the child had already been operated upon unsuccessfully. If this were done again, the condition of things would probably not be changed. It was very easy to put in a blunt-pointed bistoury, divide the septum, separating the anus from the cavity of the rectum, and thereby give immediate relief; but this would not be permanent. Mere incision and subsequent dilatation would be futile. A more radical operation was called for.

That which offered the most promising results was a complete circular resection of the thickened tissues and the drawing down of the gut from above and joining it to the skin below. If the stricture was too high to admit of the drawing down of healthy rectum to the healthy skin, then it was usual to excise a portion of the coccyx. He would advise an early operation. It would have been better to have it done immediately after birth. If the operation did not succeed, there was still left an inguinal colotomy. The time had gone by when a child was to be relegated to the grave rather than make for it an artificial anus. If the necessary care was taken to insure regularity of the bowels, the condition was by no means an insupportable one. He believed that inguinal colotomy was the best operation at birth in a very large number of cases.

Congenital Hydrocephalus without Enlargement of the Head.—The Chairman presented a brain removed from a child, who had died at the age of three weeks, in which a very marked degree of hydrocephalus existed, the head, however, being of normal size. The lateral ventricles were much dilated and contained six ounces of fluid. The brain outside was a mere shell. Spina bifida also existed. Death was caused by suppuration in the spina-bifida sac, which had extended upward along the whole cerebro-spinal axis. No operation had been performed.

This was the second case this year in which an autopsy had revealed this condition without enlargement. There was no history of blood disease in the case just reported, and the child had died of acute empyema.

A Study of One Hundred Cases of Pneumonia in Children.—Dr. W. L. Stowell read a paper with this title.

Dr. Francis Delafield said that it seemed necessary to have a well-defined idea of the kind of pneumonia under consideration—whether it was a broncho-pneumonia or croupous pneumonia. He thought the difference well marked, not because there was bronchitis in the one and not in the other, because, as a matter of fact, bronchitis, to a greater or less extent, was present in all forms of pneumonia; not because of the consolidation of a portion of a lobe in the one and of an entire lobe in another, for consolidation of the whole of one or more lobes was common enough. The real difficulty seemed to lie in the character of the inflammatory processes. Croupous pneumonia appeared to be an exudative inflammation in which the blood-vessels alone were concerned, the affected portion of the lung becoming infiltrated with serum, fibrin, and pus. These inflammatory products were, if the case was of moderate severity, absorbed, and after a time the site of the inflammation became practically in the same condition as before the attack. Broncho-pneumonia was, however, quite different. It was an inflammation with the formation of new connective tissue in the walls of the bronchi and air vesicles surrounding the inflamed parts. The inflammatory processes were likely to last a long time, it was much more difficult for the tissues to return to their normal state, and there was great probability of a subacute or chronic inflammatory condition being left. Broncho-pneumonia was the

characteristic variety in young children, though the croupous form did occur. In adults the opposite was the rule, while in the intermediate ages a greater variety was met with. As to whether alcohol was likely to further or to hinder recovery, he had, he said, a very strong objection to giving alcohol to children under five years of age. For adults he was in the habit of ordering it, when indicated, in very large quantities. He had never seen a child with pneumonia take alcohol without, in his opinion, being the worse for it. The question of the advisability of antipyretics in pneumonia must be subdivided—on the one hand, whether they should be given to secure greater comfort to the children or with a view to lessen their chances of dying. He did not believe they had much effect on the mortality, unless given in unreasonably large quantities. They might be used in small doses for the purpose of promoting comfort, and he thought that children bore the disease better by reason of their use. He looked upon an abortive case as an acute inflammatory process running a short course. He had never been able to believe that these short cases were short as the result of treatment.

Dr. J. E. Winters thought croupous pneumonia comparatively frequent in children. He thought the majority of physicians would admit that they saw very little broncho-pneumonia in private practice. It was likely to occur in certain epidemics of pertussis and of measles. When one saw cases of circumscribed consolidation of the lung in infants, running a rapid course and terminating in recovery, these might be put down as being cases of croupous or lobar pneumonia. His views on the subject of alcohol in croupous pneumonia were the same as those of Dr. Delafield. As to antipyretics, it was not often that the temperature in lobar pneumonia needed any interference. If an attempt was made to reduce the temperature in broncho-pneumonia, more harm than good would be done. As to aborting the attacks, he had seen a great many of these cases in which it was stated that the attack had been aborted. It was a question whether these were cases of pneumonia at all. Certainly it was possible to find cases of an inflammatory process with some exudation which would terminate in from forty-two to seventy-two hours, but such were rare. A child with some disturbance in the alimentary canal, with a cold added thereto, would soon get up a high temperature and exhibit many of the signs indicative of pneumonia. After the use of medicines acting upon the intestines and skin, the symptoms disappeared and nobody could say whether pneumonia had existed or not.

Dr. J. L. Smith said he thought it convenient to recognize three forms of pneumonia in children: (1) catarrhal or bronchial, (2) croupous, and (3) hypostatic. He thought that the first-named might be aborted. He was surprised to hear Dr. Delafield's views on alcohol. He thought its medicinal value unquestionable. Of course, like any other medicine, it would be harmful in over-doses.

AMERICAN GYNÆCOLOGICAL SOCIETY.

Fifteenth Annual Meeting, held in Buffalo, September 16, 17, and 18, 1890.

The President, Dr. John P. Reynolds, of Boston, in the Chair.

(*Continued from page 441.*)

The Question of Amperage in the Treatment of Fibroid Tumors by Electricity was the title of a paper by Dr. W. C. Ford, of Utica, N. Y. Myomatous growths, he said, were easily managed by galvanism. They were of comparatively low resistance, a very large and hard one offering but 300 ohms. The question had been asked, What happened when the current passed through a fibroid mass? Simply the separation of the fluids in this mass and their re-formation into different chemical combinations, that interfered with the intra-uterine existence of the growth. This was merely a process of electrolysis. The current necessary to produce this electrolysis was not one of tension, but of volume or quantity, and this depended entirely on the cell used. The small bichromate-of-potassium battery with a single plate of zinc and carbon, so much in use, unless a very large number of cells was employed, did not give sufficient volume, and had not sufficient ampèrage to effect the necessary electrolysis, but by using a larger cell, having a zinc plate between two good-sized carbon plates, say seven by two, we got a greater surface exposed for chemical action, and hence a greater volume or ampèrage of current, which afforded sufficient electrolytic action to decompose the fluids of the fibroid tumor and arrest its growth; but with high tension and low ampèrage, as in the small-cell battery, this result could not be accomplished without employing a great number of cells. The latter had an electro-chemical action or cauterizing action, while the former produced simple electrolysis.

The author used the negative or active electrode in the uterus, and the positive electrode externally over the abdominal wall. His uterine electrode consisted of a pure platinum needle with a blunt end, like Apostoli's needle. He had also used the gas-carbon electrode. For an abdominal electrode, a plate of copper covered with punk was substituted for Apostoli's clay electrode. The plates were of all sizes. The fluids of the tumor decomposed at the internal, negative, electrode and bubble up and run out over the electrode in sufficient quantity to be caught in a spoon speculum, after a few minutes' application, if the current had the proper ampèrage. The author had accomplished this with a battery of fifteen of the large bichromate-of potassium cells referred to. The fluid of the tumor had an intense chlorine smell and was strongly alkaline. The current was well distributed by the abdominal electrode, and there was no risk of blistering the abdomen, as there was absolutely no cauterization produced. The author was convinced that the cure of these fibroids by electricity could be brought about in no other way than by having a sufficient volume of electricity carried by the electrode to produce perfect electrolysis.

Dr. Tremaine, of Buffalo, had not been able to obviate intra-uterine cauterization even with a very mild current, and after an experience of sixteen cases he was rather disappointed with the electrical treatment. He believed the actual value of Apostoli's treatment of fibroids was still *sub judice*, and raised the question as to what became of the abdominal walls and other thin tissues; if the electrolytic action, which passed through them to get at the tumor, was sufficient to completely decompose and dissipate the tumor, why these tissues were not also decomposed.

Dr. Skene believed there was a certain amount of electrolysis going on in the abdominal walls and in the tissue intervening between them and the fibroid tumor, but that they remained intact while the tumor was dissipated, for the reason that it was of lower vitality and could not resist the decomposing action of the current. Even if the normal tissues did sustain a certain electrolytic action, their great vitality enabled them to soon regain their original condition, while the fibroid did not. He did not believe that cauterization was ever necessary to stop the growth of the tumor, and that in avoiding it all the dangers of electrolysis would be obviated. He would never carry electrolysis to the point of cauterization. He believed that electrolysis with the positive pole in the cavity of the uterus produced stenosis, and that it could be avoided by the use of the negative pole. Very few cases could ever be

said to be cured in the sense that the tumor entirely disappeared; but if we limited the word cure to mean an arrest of the growth, in that sense many had been cured. In many cases the tumor had been very much diminished in size and the symptoms had been cured, which might be called "symptomatic cure." He thought that Apostoli meant to be honest, but, like all other enthusiasts, he was inclined to overestimate his work, but in the main he was correct.

Dr. H. P. C. Wilson, of Baltimore, believed that for violent bleeding myomata the carbon uterine electrode was the proper one, and he much preferred it to the platinum electrode; that electricity was not applicable to intra-uterine pedunculated myomata, or subperitoneal pedunculated myomata, or soft œdematous myomata; but that the intramural form could be cured in the sense referred to by Dr. Skene. He believed that much of the dissatisfaction with the use of the electrical treatment was due to the fact that operators were too sanguine and used electricity for all kinds of tumors when it should only be used in selected cases.

Dr. H. Mynter, of Buffalo, called attention to Dr. Ford's statement in regard to the difference between electrolytic action and electro-chemical action, the former being produced by a moderate number of cells with a large surface and low intensity, while the latter was caused by the application of a battery of very small cells having a very high tension, and thought that perhaps the diversity of opinion in regard to electricity was due to the fact that many who administered it did not have the proper battery. He was also convinced that the electro-chemical action frequently caused sloughing.

Dr. George Keith, of Edinburgh, emphasized the importance of first making a correct diagnosis and then proceeding to treatment.

Dr. Rosebrugh, of Hamilton, Ontario, asked whether in the cases alleged to be cured there had been any other form of medication, such as with ergot employed conjointly with electricity.

Dr. Wilson had used no medication except enough to regulate the bowels and nervous system with bromide of potassium, etc. He considered ergot absolutely worthless in fibroids.

Dr. Forn had never found that the soft œdematous fibroids would not yield to electricity, but in the very hard ones he had found it necessary to cauterize in order to make any impression on them.

Dr. Gehrung, of St. Louis, believed that better results would be obtained by puncture, where it was admissible, than by treating the tumor through the walls of the uterus, and that the large exudation tumors filling the pelvic cavity and firmly adherent to all the pelvic organs—where any operation was impossible—could be treated successfully by puncture and electrolysis. He used the trocar-electrode and double cannula, with two tubes attached, through which, by the use of the aspirator, he could wash out the cavities of the tumor if it was a cystic one.

Dr. Skene thought that ergot was only useful in submucous uterine tumors with a tendency to become pedunculated, or those that were undergoing a natural process of elimination—cases which did not call for electrolysis. In cases of bleeding fibroids he would remove a portion of the hypertrophied mucous membrane of the uterus to control hæmorrhage; then apply iodine to the mucous membrane, which acted as a disinfectant; and then electricity. In cases where the hæmorrhage was not severe he would use ordinary disinfectants, but in obstinate cases he believed that *Hydrastis canadensis* was valuable and that it had a beneficial effect on the mucous membrane of the uterus. He frequently used it in connection with curetting, iodine, and electricity.

Vaginal Fixation of the Stump in Abdominal Hysterectomy.—Dr. Henry T. Byford, of Chicago, presented a paper as a supplement to one written by him a year before, in which a certain operative procedure was recommended. Extended experience had shown the advisability of making some changes in the details of the operation, particularly in the fixation of the stump. The characteristic steps of the operation as now performed were as follows: Ligate the broad ligaments; separate the bladder from the cervix; put on a temporary elastic ligature below the tumor; transfix and cut off the mass above; ligate the stump in several parts with silk; remove the elastic ligature; perforate the anterior vaginal wall in front of the cervix; turn the stump forward into the vagina, and clamp it firmly there; sew the peritoneal edge, that was separated along with the bladder from the anterior surface of the uterus, to the posterior surface of the stump, so as to close off the peritoneal cavity from the vagina; close the ventral incision, with or without toilet and drainage, as in other cases. A small piece of iodoform gauze stuffed from below into the rent in the anterior vaginal wall, and left for twenty-four to thirty-six hours, might be useful in preventing any possible accumulation of discharge at that point. The time occupied in separating the bladder and the anterior vaginal wall from the cervix and putting on the clamp-forceps should not be greater than for adjustment of the stump in ventral fixation. The other steps were practically the same. Bladder wounds could be treated extraperitoneally, without displacement of the viscus.

Dr. Byford reported eight cases, one of which had resulted fatally, but this result could not be attributed to the operation. In the others, the shortened upper end of the stump had worked its way back into the connective tissue behind the bladder, so that in a few weeks the os and cervical canal were normal as to position and mobility.

Vaginal Fixation of the Stump after Myomectomy.—Dr. Howard Kelly, of Baltimore, would divide fibroids into four classes: 1. Those that were pedunculated and intra-uterine, which could be removed from the cervix. 2. Those that could be removed through the abdominal wall by myomectomy without removing any substantial portion of the uterus. 3. Those with a distinct pedicle, which could be removed by supra-vaginal hysterectomy; also those in which a pedicle could be formed, but where it was necessary to cut under the tubes and ovaries and through the broad ligament to get at it. 4. Atypical cases, where the tumor was spread out laterally in the broad ligament, almost filling the pelvis, where it was impossible to make a pedicle, and the patient usually died from hæmorrhage and shock. These latter cases could not be treated by section, which was limited to cases with a distinct pedicle; and there was no well-defined method of treatment for them. In treating these fibroids, one must consider first that there was a very large, fleshy pedicle, the ligating of which controlled the hæmorrhage at the time of operation, but that it might bleed profusely after it had been dropped back into the abdominal cavity, and thus prove a source of contamination. He compared Hegar's method of treatment—the extraperitoneal—and its modification by Zweifel; Schroeder's—the intraperitoneal; his own—a modification of the two; and Dr. Byford's. The first had had such a death-rate that it had been abandoned, but subsequently rendered legitimate by Zweifel, who performed it with more care. Hegar's method of allowing the stump to slough off he considered as unsurgical a procedure as to tie a string around the finger and allow it to slough off. It was also very difficult where the stump was short. To overcome this difficulty, he had adopted the plan of suturing the stump with buried and superficial sutures and suspending it in the lower angle of the abdominal

incision. A square pad of iodoform gauze was placed over the external end of the stump, through a hole in the middle of which the sutures, left with long ends, were drawn and could be grasped with the forceps at any time in case of accident, thus giving complete control of the stump. This had stood the test of nine cases with but one death, which had been due to vascular lesions. Dr. Byford's method was good for the smaller tumors, but it would be very difficult to deal with a broad pedicle by it. It had the advantage of avoiding the risk of hernia which followed from suspension of the tumor in the angle of the abdominal wound, and also afforded excellent drainage.

Dr. William M. Polk, of New York, referred to the fourth class of tumors mentioned by Dr. Kelly, which he treated by a plan that was a modification of the one suggested by Dr. Miner, of Buffalo, in the treatment of non-pedunculated ovarian tumors —a process of complete enucleation. He would ligate the uterine artery, and in some cases where there was a good deal of hæmorrhage from the posterior wall he thought it advisable to cut down and ligate the utero-sacral ligament on either side, in order to control the hæmorrhage. He burned a hole with the cautery through the cervical canal, burning the tissues well around the hole, after which the cavity was packed with a long strip of iodoform gauze, which was brought out of the opening, and the abdominal incision was closed in the ordinary manner adopted in the treatment of ovarian tumors that were enucleated in a like manner, thus affording complete disinfection of the cervix.

Dr. E. C. Dudley, of Chicago, had performed Byford's operation in two cases with perfect success, with a simple modification in the packing of iodoform gauze.

Dr. A. J. C. Skene, of Brooklyn, thought that Byford's method was only adapted to cases where the stump was small. He believed that complete removal of the cervix might be substituted for Byford's operation, also in dilatation of the cervix and complete inversion of the same. Before adopting Byford's method the relative value of these other two methods should be ascertained.

Dr. Dudley had tried inversion of the stump, and found it exceedingly difficult and almost impossible to accomplish, no matter how much dilatation was used. He had also attempted the removal of the entire stump by applying the lock forceps through the vagina to secure hæmostasis, but believed it a very difficult and not very practicable operation. Dr. Byford's method should be adopted in all cases of large fibromata which completely filled the uterus and spread out into the broad ligament, especially if the size of the cervix was reduced by the cautery, as spoken of by Dr. Polk. The vagina was quite capacious and would hold a pretty large stump.

Dr. Joseph Taber Johnson, of Washington, had successfully performed five operations by the Bantock method. He thought it was better to have a long convalescence caused by the sloughing off of the stump in this operation than to try some other operation and have no recovery at all. He believed the method referred to by Dr. Skene of the complete removal of the infected stump, providing proper drainage, would be the ideal method.

Dr. Polk agreed with Dr. Dudley that the operation for the complete removal of the uterus and cervix by applying clamps through the vagina to control hæmorrhage was a very difficult and unsatisfactory operation, and was inferior to the complete removal of the uterus by the use of the ligature, notwithstanding the fact that in some cases where the cervix was deep that operation was prolonged by a good deal of bleeding. Dr. Byford's method had the advantage of simplifying and shortening the operation. Another method suggested about the same time, or since Dr. Byford's, that accomplished about the same end, was that in which, after the stump was cut off and the bladder dissected away, instead of making an opening into the vagina, with one blade of the scissors in the cervix and the other outside, the cervix could be cut down into the vagina and the mass turned inside out, on the same principle as in the Porro operation.

Dr. Kelly believed there was still another class of cases in which hæmorrhage could not be controlled by the methods described by Dr. Polk and others, and for those cases he had devised a corrugated uterine sound by which he could discover the relative position of the uterine arteries when they were displaced, and in that way control the hæmorrhage. These tumors, no matter how large, seldom reached to the ovarian arteries and veins at their points of emergence from the abdominal aorta, and he would in cases of excessive hæmorrhage tie these arteries and veins in the abdominal cavity, and in desperate cases, where it was impossible to get the tumor out, he would adopt the heroic treatment of temporarily compressing the abdominal aorta; and he was convinced that there was a certain class of cases that could not be treated in any other way. In his own operation, if there was any oozing after the stump was sutured, he ligated the uterine arteries, and had always succeeded in checking any hæmorrhage that might have occurred. Bantock's operation was fitted only for cases of pedunculated fibroids, and, if it was applied strictly to such cases, the mortality should be *nil*.

Dr. J. C. Temple, of Toronto, agreed with Dr. Skene that removal of the entire mass was the most rational procedure. He did not believe in the inversion of the mass through the dilated cervix, as he had found it a most difficult method. Dr. Byford's plan was a good one in selected cases where it was not desired to remove the whole of the tumor.

Injuries to the Ureters during Labor was the title of a paper by Dr. A. J. C. Skene, of Brooklyn. The writer stated that he had attended many cases in both hospital and private practice that differed from the puerperal diseases recorded in obstetrical literature. He had been led to believe that the symptoms he had observed were due to injury to the ureters. The patients had usually been primiparæ or had had many children; the labor had been tedious, instrumental, or manual, and the progress after delivery satisfactory or fairly so. The lochial discharge and the secretion of milk had been normal, and the bowels and the kidneys apparently normal. In some cases there was retention of urine or frequent and painful urination. Pelvic pain and tenderness in the lower part of the abdomen were present, but were not always severe at first. These symptoms became more acute after a time, the pain and tenderness increased rather abruptly, and a chill might occur at this time. Distention of the bowels took place, and the temperature and the pulse-rate increased. Pressure showed increased tenderness, and bimanual manipulation of the kidney on the affected side usually produced a sense of distress rather than of acute pain. An increase in the severity of the symptoms supervened in from three to five days, and soon thereafter a quantity of pus, and sometimes blood, appeared in the urine. The patient was generally relieved to some extent when the discharge of pus began; the pain was less and the temperature and pulse-rate were reduced a little. In connection with pus and blood, renal casts might be found. The pus continued to be discharged, but in diminished quantity, for a week or more. The bleeding generally subsided in a day or so, and most of the patients recovered. In some other cases acute disease of the kidneys appeared about the time that pus began to be discharged from the bladder; uræmia followed, and sometimes uræmic coma. Such cases usually terminated fatally, although recovery might take place. In most instances there was not a pre-existing renal disease.

The diagnosis of injury to the ureter must be made by the exclusion of the more common puerperal affections—such as peritonitis, cellulitis, general septicæmia, cellular abscess, and cystitis. If there was a metro-cellulitis following injury to the cervix uteri, the ureters became affected secondarily, and the symptoms developed in reverse order.

The following was a convenient classification of diseases and injuries of the ureters: 1. Injuries of the ureters during labor. 2. Obstructions to the ureters secondary to pelvic inflammations. 3. Obstructions due to neoplasms and uterine displacements. The second and third were taken from Engelmann.

Injuries to the ureters might be avoided in great measure. Care to dilate before rupture of the membranes, the proper use of the forceps, and having the patient in the best possible physical condition, were essential as prophylactics.

The treatment was in great measure expectant. The surgical treatment of these affections was not in a highly developed state.

Incontinence of Urine due to Malposition of the Ureter was the title of a paper by Dr. F. H. Davenport, of Boston. This was a report of a case in which a woman of twenty-nine years had suffered all her life from incontinence of urine. A careful examination showed that one ureter, instead of opening as usual into the bladder, was continued along in the septum between the bladder and the vagina, and emptied by a special opening near the meatus. An operation to establish a proper opening into the bladder was clearly the only hope of relief. This was performed, but a subsequent retraction of the vesical end of the ureter had made a second operation necessary. The latter had been successful.

Dr. W. W. Jaggard, of Chicago, thought that injuries to the ureters were quite common during pregnancy, and that those existing before pregnancy might become intensified, but that they were not common during labor, as at that time the bladder was drawn up into the abdominal cavity and the ureters were out of the way of the pressure from the head of the child; that they were rarely injured by the dilatation of the cervix or the application of the forceps before the engagement of the head. In 1878 a German observer had called attention to compression or dilatation of the ureters as a cause of eclampsia, and Morgagni had noticed the same thing. The speaker had seen one case where compression was believed to be the principal cause of eclampsia. Recent anatomical investigations with frozen sections of women who had died early and late in the puerperium, particularly in cases of difficult labor, had demonstrated that the bladder was then an abdominal and not a pelvic organ. Among the causes specially operative in producing injury of the ureters during pregnancy he mentioned: 1. Increased abdominal tension. 2. The presence of small ureteral calculi. He had seen two cases in which calculi were probably the cause of a dilated ureter. He believed that palpation of the ureters during the puerperium was extremely hazardous, productive of no good, and entirely a work of supererogation.

Dr. A. W. Johnstone, of Danville, Ky., related a fatal case of injury to the ureter after laparotomy for multilocular ovarian cyst, where furious mania was developed forty-eight hours after the operation. The tumor pressed on the ureter just where it passed over the pelvic brim, and from that point up to the kidney it was so enlarged that it would admit the finger; there was purulent inflammation of the ureter and hilum of the kidney, and the kidney itself was seriously disorganized. The lower portion of the ureter was normal. He believed that many of the cases of mania after laparotomy were due to some such condition as this. Tuberculosis was a very frequent disease of the ureters, and had been noticed in a young girl who was supposed to be dying of phthisis, who presented no complication of the lung whatever, but had all the symptoms of tuberculosis. The post-mortem revealed the bladder, the ureters, the hilum of the kidney, and the kidney itself studded with miliary tubercles. The ureters were a frequent source of trouble, and should not be overlooked in gynæcological work.

Dr. Henry T. Byford, of Chicago, thought that in many cases of pelvic disease death was due to ureteral trouble, such as uræmic convulsions, etc., although they were generally attributed to the earlier disease which caused the ureteral trouble. Catheterism of the ureter was difficult and required a practiced hand, but it was unreasonable to doubt that it could be done.

Is the Mortality after Gynæcological Operations affected by Climatic Influences?—Dr. Henry C. Coe, of New York, read a paper on this subject. The conclusions that he had drawn, after a most careful analysis of his own cases and extended inquiry in regard to the cases of others, were against the belief that season had any influence in the way of affecting the mortality rate after gynæcological operations.

Cephalæmatoma.—In a paper on this subject Dr. Howard A. Kelly, of Baltimore, stated that this disease occurred once in every two hundred and fifty obstetric cases, but that it was rarely recognized by the general practitioner. Cephalæmatoma was a well-defined lesion, running a brief, definite course, tending, as a rule, toward resolution, but capable of seriously affecting the health, or even implicating the life, of the child.

A cephalæmatoma was usually resolved by absorption, and it was wise to wait for two or three weeks. If absorption did not take place, extirpation was indicated.

Dr. Jaggard believed that external cephalæmatoma occurred in many labors and healed spontaneously, attracting little or no attention. The internal variety, where the tumor was between the inner layer of the periosteum and the bone, sometimes caused strabismus and death; it was not difficult to diagnosticate, but usually difficult to cure. He was of the opinion that injury was always the cause of these tumors, and that it occurred during labor by reason of the stretching of the periosteum downward and rupture of its blood-vessels, or by reason of the bringing together of the bones of the fœtal head by the application of the forceps. It was essentially traumatic, and occurred in a slight degree in many labors, but reached a perceptible size in about the proportion stated by Dr. Kelly. It was nearly as frequent in the after-coming-head and transverse presentations as when the vertex presented.

Dr. Fredericks, of Buffalo, reported three cases of cephalæmatoma.

Dr. Kelly was convinced that these tumors were not the result of traumatism from severe labors or instrumental deliveries, being most frequently observed after simple and easy labors. They had been detected on the head of the child before birth, on the head of a five or six months' fœtus, and in one case on the head of a child born by Cæsarean section; all of which would lead him to believe that there must be some predisposing cause that was not as yet understood.

Drainage after Laparotomy.—Dr. Thomas A. Ashby, of Baltimore, read a paper thus entitled, in which he advocated using drainage for the purpose of disposing of the products of intrapelvic operations, etc. He maintained that when drainage was employed there was a lower temperature, less tympanites, and less gastric disturbance. The abdomen should be washed out every few hours.

Dr. A. Palmer Dudley, of New York, in a series of seventy-nine cases of abdominal section, including eight hysterectomies, one Cæsarean section, two cases of extra-uterine pregnancy, and five cases of pyosalpinx, had used the drainage-tube in but

two cases (of fibroids), and both patients had died on the eighth day—the first from a circumscribed abscess of the omentum without general peritonitis, and the second from intestinal obstruction caused by adhesion of the intestines around the tube. Sixty-nine of these abdominal sections had been made without the use of a drainage-tube and without a death, although in many of them there had been a large quantity of fluid. The drainage-tube should be used only under two conditions: 1. Where there was general peritonitis and hæmorrhage was suspected. 2. Where the peritonæum was congested from a recent peritonitis and bled if irritated with a sponge. Under all other conditions the proper toilette of the peritoneal cavity before closing the abdomen would accomplish more than any drainage-tube. The drainage-tube was dangerous in the hands of those who thought they could accomplish with it what they should have done before closing the cavity. The dangers of the drainage-tube were: 1. Intestinal adhesions from the exudation of lymph around the tube. 2. Fæcal fistula. 3. Occasionally, hernia. Where there was sufficiently grave septic inflammation in the pelvic cavity to endanger life, the tube was useless, as it very soon became walled in by a rapidly forming lymph cavity and cut off from the pus that was collecting around it. The success of the laparotomists was due to great care in the toilette of the peritonæum. He had great faith in washing out the abdominal cavity with a stream of hot water. The greater drainage-tube—the intestinal tract—he took advantage of by the administration of saline cathartics just before an operation, and the vermicular action of the intestines still went on after the operation and afforded ample drainage, especially in cases of intestinal fistula. This, together with the use of hot water and careful closure of the peritoneal cavity, was safer and better than any form of drainage-tube.

Dr. E. C. Dudley, of Chicago, referred to the inadequacy of the ordinary glass drainage-tube for extensive drainage on account of its being surrounded in a few hours by the agglutinated surfaces of the peritonæum, and believed that the system of drainage devised by Michaelis, which consisted in packing the part to be drained with iodoform gauze, was a good one, and that the mistake most frequently made was in removing the gauze too soon, causing the adhesions around the gauze to break, with subsequent infection of the peritoneal cavity. He would use this system of drainage in all bad cases where there was a large surface to be drained; but, where there was doubt as to the necessity of drainage, the trial of the glass tube would serve to indicate or contra-indicate the necessity of more extensive drainage by the application of Michaelis's dressing.

Dr. H. P. C. Wilson, of Baltimore, agreed with Dr. Dudley that the glass drainage-tube was utterly inadequate to drain large surfaces, and that the Michaelis drainage was an excellent one. He referred to the frequency with which some of the European operators, Bantock and others, used the drainage-tube, the latter saying that he always felt safer when he had in a drainage-tube.

Dr. M. D. Mann, of Buffalo, thought the drainage-tube was used too much. He had almost abandoned it, and if he did use it he always felt uneasy while it was in; unless it was watched with the greatest care, very great harm might result from it; he never used it where it was possible to do without it. He would reverse the rule, "When you are in doubt, drain," and say, "When you are in doubt, wait;" don't close the abdomen too quickly unless there is great shock; put in a sponge and use hot-water irrigation, and very frequently the hæmorrhage will stop, and the abdomen may be closed without the necessity of drainage. He agreed with Dr. A. P. Dudley that drainage by the intestines was an excellent plan. He starved his patients for forty-eight hours, giving them only a little water to moisten their lips, and, by thus depriving the system of fluids, a great call was made on the lymphatics, which would take up the effused serum from the abdomen much more safely than any tube.

Book Notices.

Beiträge zur Augenheilkunde. Von Professor R. Deutschmann, in Hamburg. 1. Heft, mit 10 Abbildungen in Text. Hamburg und Leipzig: Leopold Voss, 1890. Pp. 80.

This little brochure is the first part of a series of observations on certain rare forms of disease of the eyes which have been met with in the experience of the author. The first article is a somewhat lengthy one upon the value of antiseptic procedures in the treatment of injuries of the eye. The second article consists of remarks upon the pathology of the optic nerve, with special reference to the entrance of the optic nerve into the eyeball. The third gives an account of an interesting case of homonymous hemianopsia following injury to the skull. The fourth gives an account of a very rare case of amaurosis due to self-infection from carcinoma of the stomach. The fifth is an interesting recital of the microscopic appearances of a rare form of detachment of the retina. The brochure ends with a discussion on some rare forms of ocular tumors, with microscopical examinations. Some of the articles are illustrated, and all may be read with profit. The little book is an interesting contribution to ophthalmological literature.

Hystéropexie abdominale antérieure et opérations sus-pubiennes dans les rétrodéviations de l'utérus. Par Marcel Baudouin. Avec vingt-deux figures dans le texte. Paris: Lecrosnier et Babé, 1890. Pp. x–414. [Publications du *Progrès médical.*]

Hysteropexia is the term proposed by Trélat for the operation performed by Kœberlé, in 1869, of gastrotomy with permanent fixation of the uterus to the abdominal wall. Of the various operations, the author prefers that proposed by Dr. T. Gaillard Thomas. Hysteropexia is held to be indicated in all cases of adherent or severe retroversions or retroflexions, in some cases of inversion and of prolapsus, and in grave retroversion of the gravid uterus. The danger of the operation is slight, unless there are numerous and resistant adhesions. The book is well written, and contains excellent tables of the reported cases of this operation and an extensive bibliography.

Ruptures des tendons sus- et sous-rotuliens. Traitement par la suture. Par Hervé, Docteur en médecine de la Faculté de Paris. Paris: Henri Jouve, 1890. Pp. 5 to 88.

The author finds that Ruysch, in 1720, first reported a case of rupture of the quadriceps tendon, and concludes, from a study of the published cases, that ruptures of that tendon above or below the patella are susceptible of successful surgical interference. Suture is equally indicated in recent and in old cases, and especially where there is considerable separation of the torn extremities. The operation of suturing, performed antiseptically, is not dangerous and permits of a more rapid and certain recovery of usefulness of the limb than immobilization does. The monograph is a valuable contribution to the literature of the subject.

Chronic Urethritis and Other Affections of the Genito-urinary Organs. Three Lectures delivered at the Royal College of Surgeons, in June, 1889. By Matthew Berkeley Hill,

M. B. Lond., F. R. C. S., etc. With Colored Plates from Drawings by Frank Collins, M. R. C. S., L. R. C. P. London: H. K. Lewis, 1890. Pp. viii–47.

The author of this little work has collected together some of the principal methods of treating chronic urethral discharges now in vogue. He is a close follower of Grünfeld in the use of the urethroscope, and agrees with Otis concerning urethral caliber. The book contains some excellent lithographs of the urethroscopic field and a chapter of interest on tuberculosis of the prostate, but the attempt is made to cover entirely too much ground in so limited a space.

The Intestinal Diseases of Infancy and Childhood. Physiology, Hygiene, Pathology, and Therapeutics. By A. Jacobi, M. D., etc. Vols. I and II. Second Edition. Detroit: George S. Davis, 1890. [The Physician's Leisure Library.]

The first of these little volumes is devoted largely to the subject of infant feeding, and is an exposition of the author's well-known views upon that subject. The fact that the hygiene of infants concerns the digestive organs mainly gives abundant reason for assigning to that subject so large a share of a work on intestinal diseases. The section on dentition is a judicious review of that much-discussed subject, and is especially good. On the whole, the book is eminently practical and a thoroughly good one for the general practitioner, for whom it is designed.

Protoplasm and Life. Two Biological Essays. By Charles F. Cox, M. A. New York: N. D. C. Hodges, 1890. Pp. 3 to 67.

These essays on the cell doctrine and the theory of spontaneous generation are very carefully written, including in their scope a general survey of the more recent utterances on these subjects. The author concludes that the general theory of evolution is still in the stage of hypothesis, and that the "missing link" is in the gap between inorganic and organic substances.

A Natural Method of Physical Training, making Muscle and reducing Flesh without Dieting or Apparatus. By Edwin Checkley. Third Edition. Fully illustrated from Photographs taken especially for this Treatise. Brooklyn: William C. Bryant & Co., 1890. Pp. 4–7 to 152.

The author seeks to popularize a plan of muscle-training independent of apparatus. But will not the "something or other always interfering with that half hour at the machine" defer in like manner the application of Mr. Checkley's system? However, this would have nothing to do with the efficacy of the method proposed; that would, if regularly followed, undoubtedly increase muscular tone. Physicians are notoriously sedentary as a class, and, while they may not always agree with Mr. Checkley in his theories, they will undoubtedly commend the general scope of his work.

BOOKS AND PAMPHLETS RECEIVED.

A Manual of Modern Surgery: an Exposition of the Accepted Doctrines and Approved Operative Procedures of the Present Time. For the Use of Students and Practitioners. By John B. Roberts, A. M., M. D., Professor of Surgery in the Woman's Medical College of Pennsylvania, etc. With Five Hundred and One Illustrations. Philadelphia: Lea Brothers & Co., 1890. Pp. xvi–33 to 800. [Price, $4.50.]

Epilepsy; its Pathology and Treatment. Being an Essay to which was awarded a Prize of Four Thousand Francs by the Académie Royale de Médecine de Belgique, December 31, 1889. By Hobart Amory Hare, M. D., Clinical Professor of Diseases of Children and Demonstrator of Therapeutics in the University of Pennsylvania, etc. Philadelphia: F. A. Davis, 1890. Pp. 228.

A Treatise on the Diseases of Infancy and Childhood. By J. Lewis Smith, M. D., Clinical Professor of Diseases of Children, Bellevue Hospital Medical College, etc. Seventh Edition, thoroughly revised. With Fifty-one Illustrations. Philadelphia: Lea Brothers & Co., 1890. Pp. xiv–33 to 900. [Price, $4.50.]

Ointments and Oleates especially in Diseases of the Skin. By John V. Shoemaker, A. M., M. D., Professor of Materia Medica, Pharmacology, Therapeutics, and Clinical Medicine, and Clinical Professor of Diseases of the Skin in the Medico-chirurgical College of Philadelphia, etc. Second Edition, revised and enlarged. Philadelphia: F. A. Davis, 1890. Pp. ix–298.

The Medical Student's Manual of Chemistry. By R. A. Witthaus, A. M., M. D., Professor of Chemistry and Physics in the University of the City of New York, etc. Third Edition. New York: William Wood & Co., 1890. Pp. xii–528.

Bacteriological Technology for Physicians. With Seventy-two Figures in the Text. By Dr. C. J. Salomonsen. Authorized Translation from the Second Revised Danish Edition. By William Trelease. New York: William Wood & Co., 1890. Pp. 162.

Transactions of the American Surgical Association. Volume the Eighth. Edited by J. Ewing Mears, M. D., Recorder of the Association.

A Digest of Current Orders and Decisions, with Extracts from Army Regulations, relating to the Medical Corps of the U. S. Army, Compiled under Direction of the Surgeon-General by Charles R. Greenleaf, Major and Surgeon, U. S. A. Pp. 125.

The Treatment of Syphilis of the Nervous System. (Read before the International Medical Congress at Berlin, August, 1890.) By Julius Althaus, M. D., M. R. C. P. Lond., Senior Physician to the Hospital for Epilepsy and Paralysis, Regent's Park. London: Longmans, Green, & Co., 1890. Pp. 35.

Diagnosis and Operative Treatment of Gunshot Wounds of the Stomach and Intestines. By N. Senn, M. D., Ph. D., of Milwaukee, Wis. (Read by invitation in the Surgical Section of the Tenth International Medical Congress, August 8, 1890.) [Reprinted from the *Journal of the American Medical Association.*]

Transactions of the Michigan State Medical Society. Twenty-fifth Annual Meeting, held in Grand Rapids, June 19 and 20, 1890.

Transactions of the Medical Society of the State of Pennsylvania, at its Fortieth Annual Session, held at Pittsburgh, 1889–'90. Volume XXI. Published by the Society.

Transactions of the Texas State Medical Association. Twenty-second Annual Session, held at Fort Worth, Texas, April 22, 23, 24, and 25, 1890.

Index-Catalogue of the Library of the Surgeon-General's Office, United States Army. Authors and Subjects. Vol. XI. Phædronus—Régent. Pp. 1102.

Acute Myelitis preceded by Acute Optic Neuritis. By J. T. Eskridge, M. D., Denver, Col. [Reprinted from the *Journal of Nervous and Mental Disease.*]

Comparison between Perineal and Suprapubic Cystotomy, with Report of Cases. By A. Vander Veer, M. D., Albany. [Reprinted from the *Albany Medical Annals.*]

The New Treatment of Peritonitis. By Emory Lamphear, M. D., Kansas City, Mo. (Read before the Grand River District Medical Society.)

Electricity *vs.* the Knife in the Treatment of Pelvic Disease. By W. B. Sprague, M. D., Detroit. [Reprinted from the *Proceedings of the Michigan State Medical Society.*]

Description of a Series of Tests for the Detection and Determination of Subnormal Color-Perception (Color-Blindness), designed for Use in Railway Service. By Charles A. Oliver, M. D., of Philadelphia. [Reprinted from the *Transactions of the American Ophthalmological Society.*]

Medical Education. The Address in Medicine, Yale University, 1890. By Francis Delafield, M. D., LL. D., New York. [Reprinted from the *New Englander and Yale Review.*]

Report of Carlos F. MacDonald, M. D., on the Execution by Electricity of William Kemmler, alias John Hart. Presented to the Governor, September 20, 1890.

Medical Communications of the Massachusetts Medical Society. Vol. XV, No. 1, 1890.

Eighth Annual Report of the Provincial Board of Health of Ontario, being for the Year 1889.

A New Method of Suture in Perineorrhaphy. By George M. Edebohls, M. D. [Reprinted from the *American Journal of Obstetrics and Diseases of Women and Children.*]

Heredity-Criminality, etc., *vs.* Education. By Sophie McClelland, of New York. [Reprinted from the *Medico-legal Journal.*]

Proceedings of the National Conferences of State Boards of Health at the Seventh Annual Meeting, held at Nashville, Tenn., May 19 and 20, 1890.

Miscellany.

Mortality in Cities in the United States.—The following table represents the mortality in the cities named, as reported to Dr. John B. Hamilton, Surgeon-General of the Marine-Hospital Service, and published in the Abstract of Sanitary Reports for October 24th:

CITIES.	Week ending—	Estimated population.	Total deaths from all causes.	DEATHS FROM—									
				Cholera.	Yellow fever.	Small-pox.	Varioloid.	Varicella.	Typhus fever.	Enteric fever.	Scarlet fever.	Diphtheria.	Measles.	Whooping-cough.
New York, N. Y.....	Oct. 18.	1,646,098	618	..	..	..	..	..	..	14	4	15	7	6

Bromidia in the Treatment of Tetanus.—In the *Journal of the American Medical Association* for July 19th there is an account, by Dr. Robert Reyburn and Dr. A. W. Tancil, of Washington, of a case of traumatic tetanus, ending in recovery, in which bromidia was employed. The clinical history was furnished by Dr. Tancil, and Dr. Reyburn added the following remarks:

The case is a typical example of the more chronic variety of traumatic tetanus, and is interesting because it illustrates very well what I believe to be the correct method of treatment of such cases. The reflex action of the great nervous centers, and more especially the spinal cord, is so immensely exaggerated in tetanus that the slightest noise, the exposing the patient to a current of cold air, or even a slight movement of the patient, may develop a fatal spasm either of the muscles of respiration, or some other of the group of muscles which control functions necessary to life. Unfortunately, I have had so much of an experience in this disease from the year 1862 to the present time as to have seen every variety of treatment tried, including all the narcotics and nerve sedatives of the Pharmacopœia, also the continued use of chloroform and ether by inhalation. Anæsthetics, however, while they for a time do seem to modify and control the spasmodic contractions of the muscles, have in my experience never effected a cure. The only treatment that I have found to be reasonably successful is with morphine given in large doses and in combination with bromide of potassium, but in order to do any good with the remedy it must be given in double or triple the ordinary doses and continuously; in other words, you must keep the patient in a condition of semi-narcotism all the time for days or weeks if necessary. In the treatment of this case it was found absolutely necessary to disregard the ordinary rules of dosage and to give with a liberal hand the bromidia in quantities sufficiently large to keep the muscles relaxed. Several times during the early stages of the treatment of the case the attempt was made to diminish the doses of the powerful agents used, but the aggravation of the trismus and the painful and powerful contractions of the muscles of the abdomen and extremities compelled a return to the larger doses. Patients suffering from traumatic tetanus, as a rule, in the cases I have seen, die from violent contractions of the respiratory muscles, which stop respiration, and, of course, they die very suddenly and unexpectedly. Another most important point in the management of these cases is to insist upon the most absolute rest and quiet. The patient is to be placed in the darkest and most secluded corner of the house, away from noise and secure from the well-meant but often fatal kindness of visitors and friends. Many a case has been doing well when the excitement of a strange face or a visit from a friend may bring on a spasm which may instantly prove fatal.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Lectures and Addresses.

AN ADDRESS ON THE PRESENT POSITION OF ANTISEPTIC SURGERY.*

BY HENRY O. MARCY, A. M., M. D., LL. D.,
BOSTON.

THE treatment of operative wounds has from time immemorial been considered a subject of vital importance in the healing art. In evidence that there is nothing new under the sun, it is now alleged that recent researches demonstrate that the early Greeks were familiar with, and for quite a period at least taught and practiced, what we consider fundamental in modern aseptic wound treatment.

Upon the one hand the philosophic observer holds ever prominent in consideration the, so to speak, *x* factorage of individual type, the vital resistant power. This is subject not alone to modification in the individual—as, for example, by age, physical vigor, surroundings—but is also represented by family type, as heredity, which is easily broadened out in general consideration to climatic influence, race, etc.

On the other hand, we have actively discussed the various changes which are observed to go on in wounds under different conditions seemingly with little profit until within the present generation. There still remain many interesting minor questions of great interest and importance for consideration, and which our present knowledge still affords an inadequate means for definite solution. The ever-present material for infection and the reason of its non-development in a very considerable class of wounds has been accepted by many as sufficient evidence for discarding the conclusions arrived at by the earlier advocates of antiseptic surgery. To many superficial observers it seemed to be sufficiently proved that the entire system was untrustworthy and impracticable. Scientific data were certainly wanting to answer clearly the queries which arose, although in general the reply was made that the vital resistant power of the individual was sufficient to prevent the growth and development of the bacterial infection. Why, when the seed was vitalized and implanted in a culture medium ample to serve as food and retained at an equable temperature, did it not develop? Our laboratory experiments threw no light upon the question, for here, under the conditions given, reproduction was a constant factor. In wounds that were maintained at rest with careful coaptation of the parts to prevent the accumulation of fluids, where the tissues themselves remained comparatively uninjured, it was observed that a rapid proliferation of cell character ensued, which went on undisturbed to the complete restoration of the parts. This in many instances entirely failed, when the surrounding tissues were in a measure devitalized and a bloody or serous exudation had taken place.

In the first instance Nature did not furnish the conditions for the development of the ferments accidentally introduced into the wound, while in the second the developing medium was ample.

The query arose as to what became of the vitalized organism which failed to develop, as well as the reason of the failure. The observations of Metschnikoff upon the power of the leucocytes to surround and destroy, so to speak, to digest the bacteria under favorable circumstances, are now generally known. These observations are of interest as a possible explanation of this hitherto unknown quantity in the problem, the so-called vital resisting power of the tissues, which may vary greatly in individuals. Sir Joseph Lister very properly emphasized this fact in his address before the late International Medical Congress held in Berlin. Although such an important communication, given by such a master, to the medical profession, under the auspices of the great congress, will early be familiar to all, I have reason for briefly referring to it at this time. After giving Metschnikoff's experiments, which demonstrate that the spores of anthrax failed to germinate in the tissues of the green frog, because of the action of the leucocytes, Sir Joseph Lister refers to certain of his own studies which seemed earlier to teach "that a blood-clot within the body may exert a powerful antibacteric agency." How this took place had remained hitherto a mystery. It is certainly demonstrated that in wounds of the first class referred to, while the fluid exudation is minimized and the leucocytes are abundant, septic conditions much more rarely supervene, and the important observations of Metschnikoff, so far as they go, offer a plausible solution of a hitherto unknown resultant condition. It is quite too early to draw general deductions from our present premises and declare that in this the entire solution is found, but there is every reason to believe that this is an important discovery of a power which the organism brings to rescue it under favorable circumstances from impending danger. The practical deduction of the lesson is that we seek to place the wound in such a condition that the phagocytes of Metschnikoff may be made the active allies of the surgeon. All this helps also in a measure to explain the successes which surgeons have obtained by means which seemed directly opposite in their methods of wound treatment.

Let us interrogate a little more closely Nature's processes, which, in a general way, are well known to us all, and ascertain, if we may, the manner of repair which ensues in the minor subcutaneous injuries of every-day life. Here a small blood-clot, located in almost any part of the body, undergoes with considerable rapidity the changes which lead indirectly to its disappearance, and results in a complete restoration of the parts to their normal condition. We find the borders of the blood-clot about the separated tissues invaded by leucocytes, which appropriate for their own further development the material of the exudate; little by little, minute capillary vessels are formed in the line of these invading cells, and the process of clot-disappearance and granulation-tissue development go on *pari passu* until the clot has disappeared and new connective tissue restores the part to its former condition. A small blood-clot in the line

* Read at the meeting of the Boston Gynæcological Society, October 9, 1890.

of a clean-cut wound, when aseptic, does not materially interfere with the process of repair, and is appropriated, as in the first instance, by the leucocytes or germinating tissue cells. In an open aseptic wound, the granulation tissue which closes it germinates in a similar manner, and the surface, which has the appearance of a clot, readily bleeds upon injury, owing to the lesion of the newly formed capillaries.

A somewhat similar series of observations of equal interest and importance are seen to ensue about the ligature of an artery in continuity when the surrounding parts are maintained in an aseptic or healthy condition. Here repair takes place by the host of little workers leading up their forces in different directions. The blood-clots in the extremity of the occluded vessel undergo changes not unlike those already referred to in other locations, while the leucocytes speedily surround and shut in the material used as a ligature, forming a capsule. At an early period this may be lifted away from the thread, more or less distinctly as a layer, and little or no change has taken place in the constricting material, although this may differ very widely in character.

Even when applied to the vessels of very young animals, after a considerable period, the silk ligature is comparatively unchanged. Often at the end of three or four weeks it may be found intact, although firmly shut in by a sheath of new connective-tissue cells.

When the tissues are held at rest, the same general condition may be observed if silk-worm gut or silver wire has been used. After a period of some weeks the silk ligature may have completely disappeared, and the changes which have led up to this are traced in an invasion of leucocytes between the strands and fibers of the silk, slowly separating them and causing their disintegration. If these conditions are interfered with in a mechanical way, this process seems to be held in abeyance.

The cell changes which should go on in the development of connective tissue fail, and then the little army of workmen invade the surrounding tissues, and the processes, earlier called proliferating, ensue, and the constricting material is thrown off as a foreign body. When an aseptic animal ligature has been used, catgut or tendon, and the parts about maintained in a healthy state, the ligature material becomes invaded by leucocytes, which utilize it for their own development, causing it, little by little, to disappear. So marked is this process that an aseptic animal suture, introduced into various parts of a healthy young animal, may for a considerable period be traced by a line of newly developed connective tissue, although not a single vestige of the original material remains. These processes, which I have described at some length, have for a long time been recognized in a general way and accepted, and yet we are all familiar, almost equally so, with the reverse of the picture, where any considerable colony of micrococci develop in the line of a wound.

Here this process may be completely local; that is to say, the leucocytes surround and shut in the invading army with a wall of living granulation cells until, little by little, it is forced to surrender, and a localized abscess is the sum total of damage. The most of us, however, who were surgeons of an earlier day recall the too common and, I am sorry to admit, even at present, not rare experiences in the every-day work of many—the foul suppurating wounds and general systemic poisoning. In such wounds the feeble barriers of leucocytes, thrown up against an invading army, fail to protect the organization, and the much-dreaded "blood poisoning" supervenes.

If it may be accepted, in a general way, that the above descriptions are correct, let us use them as basic and fundamental, from which to draw further conclusions. If we find in the so-called phagocytes of Metschnikoff the familiar leucocytes above mentioned, we certainly have, in a very considerable measure, an explanation of the vital resisting power of the individual organism. If, under favorable circumstances, these cannibalistic little workmen not alone surround, but actually eat up their enemies, we have the best of reasons for understanding why the comparatively few germs in the atmosphere of a healthy locality are far less dangerous to wounds than was earlier supposed. Again, too, we see that in the so-called surgically clean wound—that is, a wound where great care is taken to exclude foreign material, where blood-clots are removed, and the comparatively uninjured clean-cut surfaces are closely approximated—the reparative processes go on steadily, and rapid recovery supervenes, although in a strict scientific sense the wound is not aseptic.

In wounds where the surrounding tissue is devitalized these favorable conditions are not maintained, and here the germination of bacteria goes on much as seen in laboratory culture experiments.

I am constrained to believe that very few scientific observers or practical surgeons can be found who will not admit that the bacterial infection is one of the chief factors in the problem. This seems so clearly demonstrated from oft-repeated and critical observation that it may be accepted as a fundamental scientific truth. The greatly varying conditions of the infecting material, as well as that of the general organism, make possible the extremely confusing factorage, often kaleidoscopic in its changing forms, of the problem.

It is quite twenty years ago since a good fortune enabled me to profit from Lister's personal instructions, and I have watched with a never-failing interest the various phases of the discussion of the subject of wound treatment until the present. Mr. Lawson Tait, of Birmingham, during all these years has been the most heterodox of unbelievers. This noted surgeon, most intense in his personal convictions, has abundantly demonstrated by his practical experience that wounds treated in utter disregard of what he calls Lister's theories do exceptionally well. He is a rapid and dexterous operator, observes most carefully the conditions and surroundings of his patients and the most scrupulous cleanliness of the operative field, and maintains a clean, dry wound of the tissues with the minimum of injury. He laughs to scorn the idea of bacterial infection in such wounds, since he maintains that these conditions render bacterial development impossible. This sturdy knight sees only the obverse side of Sir Joseph's golden shield, and

with vigorous home thrust, in a recent address,* declares the whole basis of antiseptic surgery "an absolute and ludicrous logical error." To show that Mr. Tait is really, notwithstanding his loud outcry to the contrary, in acceptance of what I consider the very basis of aseptic surgery, I quote the following from the above address: "The ordinary bacilli of decomposition will not attack, at least will not produce, these ordinary phenomena in living tissue, but they do so in dead tissue. Inclose some dead tissue with the necessary germs in living tissue, and you get a disturbance very fairly proportionate to the dose given. If the dose is small, or the tissue not very favorable for decomposition, the constitutional disturbance is slight. Thus a piece of dead beef as large as a walnut introduced into the calf of a man's leg would speedily excite a tremendous disturbance, but a piece the size of a millet-seed would probably give no trouble. An ivory peg thrust into a bone rarely gives trouble, and leaden bullets lie quietly even in the brain for years, because, though such tissue is dead, it is not prone to decomposition. Under the term *tissue* I include, of course, blood-clot and serum. Such tissues, when effused subcutaneously, may be either maintained in a really living condition, or they may become dead; on this most important question we really have no knowledge, but we know the fact. Whether living or dead, if protected from the access of germs, they do not decompose. The familiar example of a broad ligament hæmatocele proves this up to the hilt. Leave it alone, and the chances are fifty to one that it will slowly disappear without giving trouble. Open it or tap it—that is, admit the ordinary germs of decomposition—and you will secure abundant suppuration without fail. This is exactly the same thing as Lister's famous clot experiment, which Nature herself has been showing us in black eyes and other contusions for centuries. . . . If Sir Joseph Lister would witness the facts of the case, as they are in my practice daily, he will see that I care not a straw for injuring the peritonæum; that in the great bulk of my operations it is already so damaged that further injury is, and must be, a matter of utter indifference, and the only fact in his whole statement concerning me which is correct is that I wash away clots (pus, serum, and a great deal more) to avoid the risk of sepsis in the residuum. This is precisely what I have been teaching for the last twelve years. Lister's view was: 'Keep out the germ matter and you may leave blood-clots (and other matters) to take care of themselves.' My view was and is: 'Get out all decomposable matter, and you can let the germs in freely.' Lister has now come round to my view, so where is Listerism now? As I said a few months ago at the debate at the Medical Society of London, 'it is as dead as Julius Cæsar, after a short life of twenty years.' . . . There are two factors in the trouble, and it can be shown conclusively that one, the germs, are wholly inconsiderable without pabulum on which to feed, while the other, the pabulum, is sure to breed trouble, because it is practically and mechanically impossible to keep the germs out; they exist already in the blood and elsewhere, and are ever present, according to the best authorities. Finally Sir Joseph Lister claims the drainage of the peritonæum as an antiseptic measure. It is not many months since we were vigorously told by an eminent authority on abdominal surgery that if the Listerian precautions were properly carried out, drainage was wholly unnecessary, indeed pernicious. When Kœberlé first taught me drainage in 1873, he told me its use was to prevent the collection and retention of material capable of decomposition. In Chassaignac's writings may be found the most minute and detailed directions for the same purpose, and the most perfect reasoning on the subject. There is hardly a possible point in which Chassaignac does not meet the whole requirements, save in abdominal surgery, which was, of course, not then invented. It is a matter of ever-increasing wonder to me how Chassaignac's logical common sense and practical proposals have been neglected, while antisepsis has driven the surgical world wild with a wholly misdirected enthusiasm."

Returning to the address of Sir Joseph Lister, referred to above, after discussing the various methods of wound infection, he says:* "In general surgery the direct application of strong antiseptic solutions is not attended with the same disadvantages as in operations in the peritoneal cavity. My practice for some time past has been to wash the wound, after securing the bleeding points, with a pretty strong solution of corrosive sublimate (1 to 500), and irrigate with a weaker solution (1 to 4,000) during the stitching, and I have had no reason to complain of the results. And yet I must confess that I have for a long time doubted whether either the washing or the irrigation was really necessary. . . . Since we abandoned the spray three years ago, we have been careful to compensate for its absence, not only by antiseptic washings and irrigation, but by surrounding the seat of operation with wide-spread towels wrung out of an antiseptic solution. For the spray, though useless for the object for which it was originally designed, had its value as a diffuse and perpetual irrigator, maintaining purity of the surgeon's hands and their vicinity as an unconscious caretaker. But if, besides the spray, we give up all washing and irrigation of the wound, our vigilance must be redoubled. Yet I believe that, with assistants duly impressed with the importance of their duties, the task would prove by no means difficult. I have not yet ventured to make the experiment on any large scale, though I have long had it in contemplation. It is a serious thing to experiment upon the lives of our fellow-men, but I believe the time has now arrived when it may be tried. And if it should succeed, then perhaps may be fulfilled my early dream. Judging from the analogy of subcutaneous injuries, I hoped that a wound made under antiseptic precautions might be forthwith closed completely, with the line of union perhaps sealed hermetically with some antiseptic varnish, and bitter was my disappointment at finding that the carbolic acid used as our antiseptic agent induced by its irritation such a copious effusion of bloody serum as to necessitate an opening for its exit; hence came the drainage of wounds. But if we can discard the application of an antiseptic to the cut

* *British Medical Journal*, September 27, 1890, p. 728.

* *British Medical Journal*, August 16, 1890, p. 378.

surfaces, using sponges wrung out of a liquid that is aseptic but unirritating, such as the 1-to-10,000 solution of corrosive sublimate, we may fairly hope that the original ideal may be more or less nearly attained. We have already made of late considerable approaches toward it. Our wounds being no longer subjected to the constant irrigation of the spray, and carbolic acid having given place to the less irritating though more efficient solutions of corrosive sublimate, serous discharge is much less than formerly and less drainage required. In many small wounds where we used to find drainage imperative we omit it altogether, and in those of larger extent we have greatly reduced it. Thus, after removing the mamma and clearing out the axilla, I now use one short tube of very moderate caliber, where I used to employ four of various dimensions. But it would be a grand thing if we could dispense with drainage altogether, without applying the very firm elastic compression adopted by some surgeons, which, besides involving the risk of sloughing of parts of low vital power, with the chance that it may, after all, fail in its object, proves often extremely irksome to the patient."

I am fully aware that even quotations so freely made render but imperfectly the ideas of these prominent teachers, although the general thought and spirit of each is fairly represented. It has recently been my privilege to see something of Dr. Bantock's work, who in the main is an advocate of the general thought which permeates Mr. Tait's teaching. There can be no question but that he exercises the greatest care in his technique as an aseptic operator, although he emphasizes his disavowal in the belief in or use of antiseptics of any kind.

The unbiased student must observe in the recent progress in wound treatment a fundamental truth based upon the repeated observations of abundant facts. This consists of three factors: First, the condition of the patient, the so-called vital resistant power; second, the bacterial infection, the seeding of the field; third, the condition of the soil, the pabulum necessary for the growth of the direful harvest. Upon this tripod at present rests the scientific basis of wound treatment. There are many workers equally earnest, equally thoughtful. It is better they should make their observations as independent original investigators. Much profit comes from the results of such heroic workers as Mr. Tait, Dr. Bantock, and many others we could mention. The recent teachings of those who advocate the so-called dry treatment of wounds convey another side view of the great fundamental truth of much value. Here primary union is prompt and there is little effusion which seems to require drainage. It will be noted that Sir Joseph Lister looks forward to the possible abandonment of drainage, which he has during the last three years greatly lessened. On the contrary, Mr. Tait, as may be inferred from the quotations, elevates drainage to a most important factor of wound treatment, and at the late International Medical Congress both he and Dr. Bantock predicted a greatly extended use of the drainage-tube. They disregard the bacterial infection, but insist upon the withdrawal of all material which could aid in its possible development.

The ideal of wound treatment is surely to restore the condition of the parts to as nearly their primal state as is possible. If this can be assuredly aseptic, then there is no bacterium to remove; if surgically clean, with accurate coaptation of the sundered parts, then there is no material which needs removal, nothing to drain. If, as we have seen, the leucocytes go promptly to work under such favorable conditions, the first series of the repair processes takes place, which ends in a prompt and speedy restoration. This should be effected under a dressing which will permit of the introduction of no foreign factorage. To this end Lister has unweariedly labored for nearly a quarter of a century. The various antiseptic dressings now so generally employed have a value in wounds necessarily drained, which must be considered open to a possible infection, but in a wound that is closed without drainage they are unnecessary, expensive, and cumbersome. Lister's ideal protective varnish is found in the closure of the wound with iodoform collodion.

My last five years of experience in the treatment of hundreds of aseptic wounds of every variety, closed in layers with buried tendon sutures and treated in no other way than by a protective layer of collodion, is cited in ample proof. Even in the major amputations such wounds go on to a speedy repair without pain or œdema of the surrounding parts. Call the various methods adopted to secure the end obtained by whatever name you will, the great fundamental principles of antiseptic surgery as enunciated by Sir Joseph Lister many years ago rest upon a sure foundation, and the results in modern wound treatment are the marvel of our age.

Original Communications.

ON THE EARLY DIAGNOSIS OF MALIGNANT DISEASE OF THE LARYNX.*

By D. BRYSON DELAVAN, M.D.,
PROFESSOR OF LARYNGOLOGY IN THE NEW YORK POLYCLINIC.

The early diagnosis of malignant disease, in general by no means easy, is nowhere more difficult than in the mucous membrane and on the glandular structures in the neighborhood of the throat. From a simple inspection of the surface of the suspected region so little may be learned that it has become the accepted custom to withhold judgment in doubtful cases until a diagnosis can be established by the aid of the microscope, or, on the contrary, excluded through the testimony of the lungs, or upon the results of constitutional treatment. Thus it would be supposed that if a thickening or ulceration of the larynx were associated with pulmonary lesions indicative of phthisis, the disease of the larynx would probably be tuberculous; that a localized tumefaction and congestion of the pharynx or larynx which seemed to yield to the internal administration of the iodide of potassium would probably be syphilitic; and, finally,

* Read before the American Laryngological Association at its twelfth annual congress.

that a similar lesion, associated with well-marked evidences of specific disease, could hardly be other than a manifestation of that dyscrasia. Accordingly, we are taught that cancer, syphilis, tuberculosis, and lupus all present characteristics which distinguish them to the eye, and that, besides the visual evidence offered, the diagnosis can be still further sustained by the corroborative evidence mentioned above.

Unfortunately, however, none of these assumptions are able to stand the test of experience. Not only are the objective appearances present in a given case of swelling or ulceration puzzling, or perhaps contradictory, but even the history of the case and the subjective symptoms are sometimes obscure and misleading. As an example of this, a large number of the cases in which the microscope has revealed tubercular disease of the tongue have been operated upon under the supposition that the disease was malignant, and the diagnosis only established upon a microscopical examination of that organ after its removal. On the other hand, obscure cases, in which the characteristic appearances of tubercular ulceration have been present, have been promptly healed by the iodide of potassium. Exceptional cases of the nature alluded to are not rare. For the purpose of arranging them more accurately and of explaining them more fully, the following classification is offered:

I. Cancer of the larynx may be uncomplicated, but the diagnosis obscured by the absence of the usual signs and symptoms. On the other hand, conditions other than cancer may be mistaken for that disease.

II. Cancer of the larynx may be associated with or mistaken for tubercular disease. Conversely, tubercular disease may closely resemble cancer.

III. Cancer may be associated with or simulate specific disease. On the other hand, syphilis may readily be mistaken for cancer.

Difficulty of diagnosis in laryngeal cancer, therefore, may present itself in two general classes of cases—namely, those in which the disease exists by itself and uncomplicated with other conditions; and, secondly, those in which the recognition of its presence is made difficult by the existence of some complicating factor.

These conditions have all occurred in the writer's experience—some rarely, others with considerable frequency—and it has seemed that no better way of describing them could be chosen than that of presenting a few of the more instructive cases bearing upon the less common varieties.

Of the uncomplicated cases seen by the writer in which the diagnosis was obscure, the following, observed a number of years ago in the dead-house of the New York Hospital, is the most interesting and unusual, and well illustrates the difficulty of diagnosis sometimes met with:

Case I.—Male, aged fifty-four, married, Italian. Denied specific disease. Badly nourished. Principal symptoms, laryngeal cough, aphonia, and occasional dyspnœa. Laryngoscopic examination made by the writer revealed apparent paralysis of the right side of the larynx with moderate thickening of the false vocal cord, the surface of the mucous membrane of which was distinctly smooth. There was slight loss of motion of the left side of the larynx, abduction not being completely accomplished and marked spasmodic action being sometimes observed. Tracheotomy was recommended, but the patient died in an attack of dyspnœa while it was being performed. The autopsy revealed a subglottic enlargement of the right side of the larynx, the surface of which was nodular, which on microscopic examination proved to be epitheliomatous, and which was completely overhung by the right vocal band and concealed by it, so that its demonstration by the laryngoscope was impossible. There was no ankylosis of the arytænoid articulations.

A more striking case than the preceding is—

Case II.—Mrs. G., married, aged thirty-five. The husband of this woman, aged forty, developed an ulcerative condition of the larynx, which presented all of the characteristic appearances of epithelioma, both to the eye and under the microscope, and which followed the usual course of that disease, and finally destroyed the patient's life. During the progress of the disease in the husband the wife also became affected with what appeared to be precisely the same condition. Her symptoms, subjective and objective, were so similar to those present in the case of the husband and so thoroughly characteristic of epithelioma, that it was impossible to offer a prognosis more favorable in the case of the one than in that of the other. With both it became necessary to perform tracheotomy. The effect in each case was, as usual, temporarily to retard the progress of the disease. Subsequently the man died. The woman, in whom the disease was limited to the right side of the larynx, meanwhile fell into the hands of the late Dr. Elsberg, who, operating upon her at repeated sittings through the tracheal opening, finally succeeded in removing the offending tissue. The patient recovered, and up to eight years afterward was often seen by the writer, in excellent general condition and with a larynx in which there existed not a sign of active disease, although the right vocal band was gone, the right side of the larynx immovably fixed, and the rima glottidis so narrow that the use of the tracheal cannula was still required. The question of the precise nature of the above case remains unsettled, as I am unable to learn that any microscopical examination of it was ever made. Examined side by side with the husband during the active stage, it was impossible to believe that the disease in the wife's case was not malignant, while the fact of its non-recurrence is strong proof of the improbability of its having been epithelioma.

The deceptive character of growths of the larynx of the papillomatous class has become almost proverbial. Not only is the eye at fault in judging of many of them, but even the microscope may sometimes lead us into error. This latter accident can hardly be misunderstood by any experienced pathologist, for it is not uncommon, in examining the whole thickness of a tumor, to find that the elements near the surface differ materially from those of the deeper portions of the growth. It would be supposed that the external appearance of an ordinary papilloma would be sufficiently characteristic. That this is not always the fact is shown by the following:

Case III.—A man, aged sixty, upon one side of whose larynx appeared three small papillomatous growths. Thyreotomy was performed and the interior of the larynx presented to view. Thus exposed to the light and under the most careful inspection, it still was impossible to detect any positive appearance of malignant disease. The growths having been removed, microscopic examination easily established the diagnosis of epithelioma. The disease recurred shortly after this, and a highly suc-

cessful extirpation of the larynx, performed by Professor William T. Bull, prolonged the patient's life for nearly two years.

It appears not uncommonly that epithelioma of the larynx is complicated with pulmonary phthisis. Indeed, a recent writer has called attention to the possibility of the dependence of the malignant disease upon the other. It is easy to understand that with the existence of the pulmonary lesion a thickening of the mucous membrane of the larynx not sufficiently well marked to excite the suspicion that it was malignant, might easily be mistaken for tubercular laryngitis, as is well illustrated in the history of—

Case IV.—John B., Ireland, aged fifty, married, porter. The patient applied for treatment at the College of Physicians and Surgeons, New York, October 15, 1882. Had always enjoyed excellent health; was not aware of any heredity; had been strictly temperate in the use of alcoholics, and regular in his habits; was a moderate smoker; gave no evidence whatever of syphilis. During the month of August, 1882, while employed as gate-keeper on the elevated railroad, first noticed a slight hoarseness of voice. This increased slowly, and soon began to be attended with a mild laryngeal cough. Soon afterward began to lose strength, appetite, and flesh.

When first examined, two months after the beginning of these symptoms, the patient appeared to be a fairly well-nourished man, of medium height and build, light complexion, and good intelligence.

Laryngoscopic examination, made with some difficulty by reason of a marked hyperæsthesia of the pharynx, revealed a condition which differed little from an ordinary chronic laryngitis. Both vocal bands were congested and thickened, the congestion extending throughout the whole interior of the larynx, but being most pronounced upon the left false cord, which was also slightly enlarged and prominent.

Examination of the chest showed physical signs of phthisis, first stage, at apices of both lungs.

By the middle of December following, the above-mentioned enlargement of the left false cord had progressed decidedly, and its surface, from being smooth and natural, began to be nodulated and uneven. This continued to such an extent that the presence of a new growth in the larynx, long before recognized and for some weeks suspected to be of a malignant type, could no longer be doubted. From this time it developed with increasing rapidity, following the usual course of epithelioma, which it was proved by the microscope to be, and finally ending with the patient's death. The autopsy showed advanced phthisis in both lungs.

Syphilis may readily be mistaken for malignant disease, even in cases where the appearances are in the main pathognomonic. This accident is of such frequent occurrence that the importance of a tentative course of specific treatment can not be too strongly insisted upon. On the other hand, malignant disease has occasionally been mistaken for syphilis, an error by no means difficult to make in view of the apparently beneficial influence of the iodide of potassium early in the course of its administration upon the former condition. Indeed, it is a matter of somewhat common occurrence for the first effects of the iodide to be markedly salutary. Within a short time, as a rule, the deceptive character of this improvement becomes evident, and, in spite of the drug, the disease makes steady progress. Where the evidences of syphilis are actually present and the use of the iodide is followed temporarily by good results, the difficulties in the way of an early diagnosis of cancer are particularly great, as illustrated in the following:

Case V.—J. W. B., aged fifty-six, consulted me for neuralgic pain in the right lateral wall of the pharynx, from which he had lately been troubled. He stated that many years ago he had contracted syphilis and had suffered severely from ulceration of the throat. Had been somewhat intemperate and had been an immoderate smoker. Examination of the pharynx revealed partial destruction of the soft palate and numerous old cicatricial bands upon it and the posterior pharyngeal wall, which were characteristic of former specific ulceration. There was slight redness of the tonsil, which extended deeply into the pharynx, but absolutely no apparent indication of thickening or tumefaction. Under large doses of the iodide of potassium there was a slight but transient improvement. The pain, however, soon returned, and, although markedly improved by the local application of astringents and particularly of nitrate of silver, never entirely disappeared. A change in the character of the pain began to take place, and it became of a more distinctly lancinating character. Suspecting the possibility that the case was malignant, the patient was seen in consultation by one of the best diagnosticians living, who promptly and positively pronounced it specific.

The redness meanwhile spread below the tonsil and across the base of the tongue, and a gradual thickening of the mucous membrane, imperceptible at first but growing more and more distinct, began to take place. The diagnosis of probable epithelioma was made, but it was a long while before the appearances were such that it could be confirmed. Later one of the cervical glands became involved and ulceration of the mucous membrane adjacent to and outside of the larynx took place. The disease progressed, and death in the usual manner resulted. The points of special interest in this case are (1) the impossibility of early diagnosis; (2) the fact that the disease was diffused and that a widespread infiltration had existed from the outset; (3) that, in consequence, at no time in its history could an operation have been performed with any reasonable prospect of relief.

From the histories quoted above and in the light of general clinical experience, it appears that numerous variations in the typical course of malignant disease of the larynx are observed. Even the most marked and constant of them are sometimes wanting during the earlier stages of the difficulty and do not develop until the latter has made considerable progress. Even the common symptoms—aphonia, cough, dysphagia—may at first be wanting, while the appearance of the growth and the general history of the case are often misleading throughout the earlier stages and do not reveal the true character of the disease until the case has become helpless. Again, pain of lancinating character, almost invariably present, will sometimes not appear early in the history of laryngeal epithelioma, particularly, according to Mr. Lennox Browne, where the growth is intralaryngeal and unilateral.

Swelling of the cervical glands is often absent in the earlier stages and may be of such late occurrence as to be useless as an early diagnostic sign, while secretion and well-defined deformity may be entirely absent for a considerable length of time.

In view of these things, it remains to us to study the value of means not fully recognized and accepted, to test

the worth of whatever new suggestions may be made in this direction, and to seek to discover efficient methods hitherto untried.

Of the first-mentioned class of methods, thyreotomy is the one most likely to challenge attention. By means of this operation the larynx may be opened and its interior fully exposed to view. Even under conditions thus favorable for the careful and accurate examination of the tumor, it is not always possible to establish the diagnosis, as was seen in Case IV, unless through the removal of the growth and its examination under the microscope, a somewhat severe procedure.

The objections to thyreotomy, therefore, are (1) the magnitude of the operation, and (2) the possibility of finding a benign growth after all. Three other and less radical aids to diagnosis have lately been advanced. The first two are based upon the pathological appearances; the third is mechanical.

1. Thickening of the mucous membrane, with marked loss of motion in the neighborhood of such thickening, implies an infiltration of the muscles which, it is said, is generally due to malignant disease. An apparent paralysis of one side of the larynx, associated with thickening upon the same side, should always call for extreme caution in the matter of prognosis.

2. As the result of numerous investigations made during the last two years, it is held by many that of new growths of the larynx, those that are papillomatous in form and the bases of which are not surrounded by a zone of inflammation are probably benign, while those which are encircled by a ring of reddened, infiltrated membrane are almost certain to be malignant. The truth of this assertion has been verified in several instances by the writer, although, on the other hand, he has found that it is not constant and, therefore, that it can not be depended upon.

3. Translumination of the larynx, first suggested by Voltolini, has been studied of late by several observers. While, by the use of the electric light applied to the exterior of the larynx, the writer has found it possible to gain tolerably satisfactory results in causing the light to penetrate the walls of the larynx, it would hardly be possible by this method to recognize the presence of an abnormal thickening which was not already sufficiently well developed to be visible to the eye by the ordinary intralaryngeal demonstration. As a means of recognizing the presence of a new growth of recent origin and of small extent, this method is at present of doubtful value. For the purpose, however, of demonstrating the relative density of an enlargement of appreciable size, translumination of the larynx is a method of considerable importance; and even in cases of the class first mentioned it may occasionally be found useful. At least it should not be entirely condemned, since it is yet in its infancy, both as regards the apparatus used and as to the skill of those employing it, and it may in the future be so perfected as to become of practical importance.

Thus, in conclusion, it will be seen that while, in cases of laryngeal cancer, all of the classical symptoms will ultimately appear, and that, as a rule, they are present from an early period, the point aimed at by this article is to demonstrate that they may be postponed until the disease has passed the stage in which it may be regarded as possibly remediable, and thus offer no real aid in the saving of the patient's life.

The presence of muscular infiltration; the occurrence of a reddened areola around the base of the tumor, if indeed the disease present itself in the form of a tumor having a base; the appearances developed by the use of transmitted light—all of these, although uncertain reliances, do add in some measure to our scanty resources, and, together with the general history of the case, the ordinarily recognized symptoms, objective, subjective, microscopical, and therapeutical, and, finally, with the training of the judgment which comes to the experienced observer from the study of many examples, enable us in most instances to determine tolerably early the true character of the disease. Nevertheless, since the only hope of saving the life of the patient may depend upon the earliest possible performance of an operation, it is evident that with the above-mentioned diagnostic resources we are still, in spite of recent allegations, far behind in the knowledge necessary to the successful radical treatment of malignant laryngeal disease.

SOME NEW LATERAL-TRACTION HIP SPLINTS.*

By A. M. PHELPS, M. D.,
NEW YORK.

In presenting these splints to this Section it is necessary for me to state briefly the object of the splints and the principle which is desired to be carried out. They are designed, first, so far as possible, to *absolutely immobilize the joint;* secondly, *to relieve intra-articular pressure.*

I am convinced that these two are the first principles to be followed in the treatment of joint disease. Fixation and rest allow the processes of repair to take place, uninterrupted by the trauma of motion. Traction relieves intra-articular pressure and controls muscular spasm.

Those gentlemen who advocate the constant moving of joints during inflammation argue that ankylosis will certainly follow unless motion is kept up. Thomas, of Liverpool, says that ankylosis is more certain to follow if motion is allowed, and that an inflamed joint is not so likely to become ankylosed if absolutely immobilized; that the ankylosis which follows is produced by the severity of the inflammation and not by immobilization.

Many also teach that healthy joints will become ankylosed if immobilized for any considerable period. In answer to them I will say that I have immobilized inflamed hip joints from ten months to a year and a half without producing ankylosis; that I have also immobilized healthy joints in animals from six weeks to four months without producing that result. (See *Transactions of the Loomis Laboratory* for 1889.)

It seems to me that those who have carefully observed

* A paper read before the Tenth International Congress, Berlin, 1890.

tubercular inflammation of this joint or its appendages will have been convinced that the spasmodic action of the muscles is a very serious element in producing the destructive changes which so frequently and so generally follow in joints not treated.

Where abnormal intra-articular pressure is present there is danger of destruction of the head of the bone even in a healthy joint, as was illustrated by one of the specimens here referred to. The hind leg of the dog was fixed over his back with plaster of Paris in a cramped position. At the end of six weeks he was killed and the hip joint examined. The head of the bone and acetabulum were red and congested, and the cartilage was commencing to degenerate. The knee joint, in which no intra-articular pressure was made, was found normal.

To the gentlemen who argue that motion should be permitted in an inflamed joint, I will say that they seem to forget that one of the laws of surgery is that where a part is inflamed it should be put at rest, whether it is muscle or joint or any other part of the body that can be immobilized. By constantly moving the joint, the delicate new tissue which Nature is trying to produce is broken up, which may lead to destruction of the joint either by necrosis or cicatricial contraction of the capsule.

I fully agree with Sayre, Taylor, Barwell, Marsh, and others that spasm of the muscle should be overcome by extension. I also fully agree with Thomas, of Liverpool, that every joint should be fixed and absolutely immobilized until all inflammatory action has subsided and a cure is effected. But I do not believe that immobilization of the joint can be accomplished without extension; neither do I agree with the first-named gentleman that extension immobilizes a joint sufficiently to attain the best results possible, but that a combination of the principles of fixation and extension should be the law. *Hence the long traction splint, which admits of motion, does not immobilize, and the patient produces injury of the joint every time he steps upon it, as is evidenced, in the vast majority of cases, by the almost constant increase of the deformity after the splint is adjusted.* Neither does a Thomas splint produce extension or relieve intra-articular pressure; hence there must be abnormal intra-articular pressure when spasm or contraction of muscles is present, which must produce congestion of the head of the bone. And then, if extension is to be applied, it should be in the direction opposite to the line of traction made by the muscles. In other words, to apply extension to a hip joint, we should not only make traction in the line of deformity, but also in a line at right angles to that deformity. To relieve perfectly intra-articular pressure, extension must be made in a line corresponding to the axis of the neck, and not with the axis of the shaft, for the following reasons: The adductors and abductors pass diagonally across the body from the pelvis to the femur. These, with other muscles, are the ones affected by spasm. *When they contract, the head of the bone is firmly drawn into the acetabulum, the force operating on a line corresponding to the axis of the neck.* The flexors act on a line corresponding to the axis of the shaft of the bone.

Busch, I believe, was first to call the attention of the profession to this fact. In 1873 Albert, of Vienna, again emphasized it, and quoted from an article published years before by Busch. He says, quoting from Busch, that "this is a second clear indication that distraction has a beneficial effect. But this purpose has not been reached by the usual method of traction. Busch has demonstrated in a manner apparent to everybody that traction ought to be made in the axis of the trochanter" (or neck). He further adds that Dumreicher says that "if you want to control the pressure it is necessary to make traction in two lines; the muscles which pass from the pelvis to the femur act in two directions. The one draws the femur toward the median line" (adductors and abductors) "and the other flexes it." (*Medizinische Jahrbücher*, Stricker's, page 454, 1873.)

When I published my article setting forth these principles last year I was not aware of the fact that these distinguished gentlemen had already arrived at and had published the same conclusions. For years I had applied the principle of double extension and had taught it to the various medical classes in the universities where I had had the honor of teaching. That the principle is correct I have no doubt, provided it is admitted that traction is necessary in the treatment of hip-joint inflammation. And I am as firmly convinced of the necessity of traction when muscular spasm and contraction exist as I am of the only scientific method of applying it—viz., in a line parallel to the axis of the neck of the femur.

Then, believing that immobilization and extension in proper lines are the law, I have constructed the following splints:

Fig. 1. Fig. 2.

To fix the hip joint, a splint must extend from the foot to the axilla. (See Figs. 1 and 2.)

Fig. 2 represents the perineal crutch, with the abduction bar (1), adjustable by means of the key (6), for the purpose of making lateral extension. The steel bar (2) is adjusted to the steel ring (3), which makes a firm crutch, the pressure coming on the tuberosity of the ischium. Adhesive straps, extending to near the body from the ankle, furnish means of extension by tightly buckling them to the straps (7, 7), the ring (3) furnishing counter-extension. The rod (5), ending in the upper ring, prevents flexion and extension of the legs. The splint is intended to prevent every motion at the hip joint, and at the same time apply extension in a line with the neck of the femur. Fig. 1 shows the crutch and splint adjusted, the patient using crutches, and standing upon a high shoe upon the well leg.

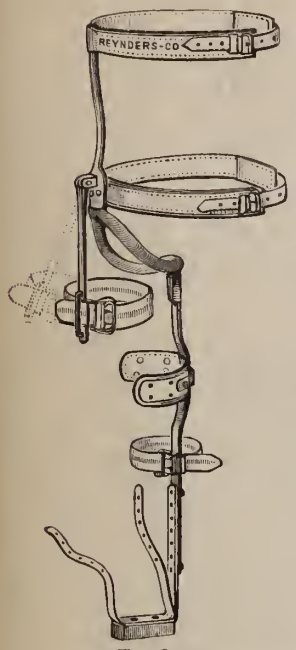

Fig. 3.

This splint I found a little too expensive for dispensary work. I then constructed the splint (Fig. 3), which simply does away with the extension joint and key. This was also too expensive for hospital work, but both splints did the work perfectly.

After a time, for my poor patients in the hospitals and dispensaries, I succeeded in perfecting a cheap splint, which applies the principle of fixation and traction in the line of the neck.

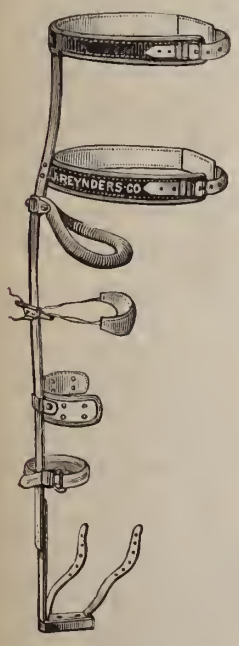

Fig. 4.

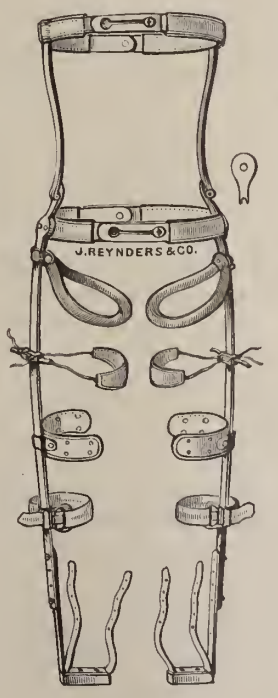

Fig. 5.

A glance at the cut will convey the idea. Fig. 4 is the single and Fig. 5 the double splint for double hip disease. The splint is a bar of steel, extending from the foot to the axilla, accurately bent to fit the body. A tracing made on paper by laying the child on it will assist in shaping the bar. A pelvic belt, a thoracic belt, and a steel perineal ring complete the fixation part of the splint. The straps in the foot-piece buckles to adhesive straps attached to the leg, which make longitudinal traction. The strap lashes the leg to the splint, making lateral traction precisely as the abduction bar acts in Figs. 1 and 2.

An ordinary blacksmith can construct this splint.

Before either these or any other splint is adjusted, however, the patient should be treated in bed until deformity is overcome and the active stage of the disease somewhat modified.

To conclude, my observations lead me to believe that the most serious element of destruction in hip-joint disease is the trauma and pressure produced by the spasm of the muscle; that fixation of the joint without extension is an impossibility; that the successful treatment of the joint must depend upon its absolute immobilization, which can only be produced by proper extension and fixation; that the constitutional treatment of hip-joint disease amounts to but little, independent of mechanical treatment; that mechanics is everything; *that extension in a line with the axis of the shaft and deformity alone, in hip-joint disease, is entirely wrong*; that extension should be *made in a line parallel to the axis of the neck*—in other words, *two lines of extension*—otherwise the idea of extension is not perfectly carried out; that ankylosis of the joint is not produced by immobilization, but by the severity and character of the inflammation; that the long traction hip-splints in general use neither properly extend nor immobilize the joint; that the intra-articular pressure results in the destruction of the joint or ankylosis in a large percentage of cases is proved by statistics; that the results in hip-joint disease should be as good as those of knee-joint disease, and will be, provided perfect immobilization can be carried out; that patients should never be allowed to step upon any portative apparatus; that a high shoe on the well leg and crutches should be insisted upon until the patient is cured; finally, *that the angular deformity seen in cured cases should not occur, and such cases are a standing rebuke to the splint and methods employed. In other words, no patient with hip-joint disease need ever recover with angular deformity.* In exceptional neglected cases of dislocation a slight amount of deformity had better be left than resort to osteotomy.

40 West Thirty-fourth Street.

Against Counter Prescribing.—"Some of the physicians of St. Joseph, Mo., have inaugurated a war on counter prescribing, which they claim has become so flagrant as to necessitate some action on their part. It is said that evidence has been secured, for presentation to the grand jury in November, implicating a number of druggists and drug clerks. It is reported that the testimony in one instance is that of a young man who suffered from syphilitic disease, and made a contract with a druggist's clerk, who agreed to cure him in four months in consideration of the sum of $6 per month. The patient is still under treatment. The law in the case is not exactly clear, but the physicians interested in the movement believe that a conviction will be secured for the violation of the medical practice law."—*Druggist's Circular and Chemical Gazette.*

PELVIC ABSCESS.

REPORT OF FIVE CASES, WITH COMMENTS.

By L. H. DUNNING, M. D.,
INDIANAPOLIS.

The following history of cases contains some points of interest which, the writer thinks, justifies their publication:

Case I.—Mrs. H., white, German, aged thirty-two years, mother of three children, was admitted to the City Hospital in February, 1890. She was said to be suffering of inflammation of the bowels. This was her third attack, and in it she had been very sick. She was, however, better on admission.

I saw her a few days after admission. She had so far recovered as to be able to sit up a few minutes at a time. She complained of great pain through the abdomen and pelvis, and had a temperature ranging fron 99° to 101°. Upon examination, found marked tympanites, yet could map out a cystic tumor with lax walls and rapid wave of fluctuation. The uterus was fixed, vagina hot, and tissues very tender. Diagnosis—ovarian tumor and purulent peritonitis due to rupture of cyst walls. Two days later, after careful preparation of the patient, an abdominal section was made. A medium-sized ovarian tumor on right side was found with universal adhesions. It was tapped, but not removed. A small tumor of the left ovary was removed. While lifting up this tumor the walls of an abscess were ruptured, and probably four ounces of pus poured out into the pelvic cavity. Upon examination of the abscess cavity, it was found to extend well down into the pelvis behind the uterus. In consequence of the alarming condition of our patient, we were obliged to hasten through the operation. The abdominal and pelvic cavities were flushed with warm sterilized water, the cystic walls stitched to the incision, a drainage-tube inserted into the cyst cavity and another one left in the abdominal incision and reaching down into the pelvis, and finally the incision was closed with deep and superficial sutures. The patient survived the operation thirty-six hours. A post-mortem examination was made, and evidences of both old and recent peritonitis were found, also numerous small abscesses in different locations in the abdominal cavity.

Case II.—L. D., colored, aged thirty-two years, was under my treatment during the months of January, February, and March of the present year for fibroid tumor of the uterus. Apostoli's method was employed. The tumor was interstitial and very hard. It was developed more on the right side than on the left, and lay well down in the pelvis. The upper border was on a level with the umbilicus. The menses had been suppressed five months, and the patient had frequent seizures of hystero-epilepsy. She had one of these paroxysms one day while upon the chair taking electricity, and furnished a fine clinical study for a number of students who were present witnessing the electrical application. In consequence of the suppressed menstruation, the negative pole was attached to the intra-uterine electrode. There were in all eleven séances. We began with thirty milliampères, and gradually worked up to one hundred and fifty milliampères. The time in employing the stronger currents was five minutes, and the weaker ones seven to ten minutes. Before and after each application the most strict antiseptic precautions were observed. In her visit to the office on April 12th the patient stated she had had a large discharge of matter from the rectum at stool each day for ten days. A digital examination *per vaginam* was made. The tumor was fixed, the tissues around the uterus hard, hot, and very tender. There was one spot in the vagina at the right of the uterus that felt slightly boggy, and here an indistinct sense of fluctuation could be elicited by combined examination. Nothing further could be learned by digital examination *per rectum*. On introducing the speculum into the rectum, quite a quantity of yellow, bad-smelling pus ran out and formed a small pool upon the chair. We concluded that the electricity had induced suppuration in the tumor, that the pelvic tissues had become inflamed, and finally participated in the suppurative process.

The opening of the abscess into the rectum was not found.

Dr. Cook subsequently examined the patient and confirmed our diagnosis, but failed to find the opening. The treatment consisted of tonic, nutritious diet, and copious injections of hot water into the rectum three times a day. When six weeks had elapsed, the discharge of pus had ceased, the tumor was diminished to less than half its former size, and the evidence of cellulitis nearly disappeared. At present the patient is feeling well, is menstruating regularly, and has had no convulsive seizures since April.

Case III.—Mrs. B., a domestic, colored, aged twenty-eight years, was admitted to the City Hospital on January 2, 1890. She gave the following history: She had been confined three years previously, and had had gonorrhœa a year later. During the last two years menstruation had been painful and scanty. At the time of admission, menstruation was exceedingly painful, there was a mere show, and she had epileptic seizures at each epoch. There was marked pain in the pelvic region, and considerable tenderness upon pressure. The temperature ranged from 99° to 100° F. The patient walked with considerable difficulty and always with the trunk bent forward.

Upon examination, laceration of the cervix and cervical endometritis were found. The right ovary was found in the *cul-de sac*, and an oblong mass above it extending toward the uterus. Both were exquisitely tender to the touch. The left ovary could not be felt, but a sausage-like mass was mapped out upon this side upon a level with the body of the uterus. This was thought to be a pyosalpinx, and a like condition believed to be present upon the right side. An operation for their removal was advised and accepted. The patient was carefully prepared, and on January 12th a laparotomy was done in the usual manner. The tubes and ovaries were found adherent, but were lifted up and removed. Both tubes were distended by pus. The left one ruptured in handling, so tense and thin were its walls. The thinnest portion of the tube lay against and was adherent to the layer of the broad ligament near the upper border. The patient made an uninterrupted recovery, having, however, several epileptic seizures during the three weeks immediately following the operation. She was discharged from the hospital in six weeks in a very good condition of general health. I saw her three months later, when she stated that she had had no convulsions since she left the hospital, and that she was able to attend to her work as a domestic.

Case IV.—Miss A. B., aged twenty-six, was admitted to the hospital August 19, 1890. A few days previously she had expelled a two-months-and-a-half embryo with membranes intact. Eight days later a second embryo was expelled inclosed in the membranes. For two or three days all seemed to go well with the patient, except that she had a slight abnormal temperature. On August 29th, three days after the expulsion of the last embryo, the temperature rose to 105·8° F., and the pulse was 135 per minute. The uterus was mopped out and irrigated. Irrigations were frequently used. Quinine, whisky, and antipyretics were given. Under this treatment the patient's general condition improved somewhat. The temperature ranged from 101° to 103° F. till September 1st. Upon that day she came under my observation and treatment. A physical examination revealed the following facts—viz.: there was slight tympanites with considerable tenderness upon pressure in the vaginal regions, more

marked upon the right side. There were secondary syphilitic sores upon the labia. The vagina was hot and the tissues were very much swollen upon the right side, where there was also bulging of the anterior and lateral walls. The most prominent point of bulging was on a level with the cervix and to the right. Here fluctuation was detected. With the assistance of Dr. Oliver and Dr. Wright, aspiration was done. A large-sized trocar needle was carried into the tissues at the point of fluctuation an inch and a half. A small amount of bloody serum was withdrawn, and two or three drops of pus followed the withdrawal of the trocar. A hot bichloride douche was given and the patient put to bed. The next morning the temperature had fallen to 99·4° and there was a slight discharge of pus into the vagina. The following day a digital examination was made and a large opening found at the point of puncture admitting the tip of the finger. Through this opening pus was discharging freely. From this date, September 3d, the patient rapidly improved, and on September 25th was walking about the wards. There is still slight discharge of pus and some thickening and tenderness of the pelvic tissues upon the right side. After the opening of the abscess the treatment was limited to tonics and stimulants and vaginal irrigations of bichloride solution (1 to 3,000).

Case V.—Mrs. P., aged forty seven years, a small, delicate, refined lady, has been an invalid three or four years. About two years ago Dr. Harvey informed her that she had a uterine fibroid. Menstruation is too frequent, is excessive and painful. There is a profuse discharge in the interval between the menstrual periods. This discharge is sometimes pus and sometimes muco-pus.

Upon physical examination, the uterus was found much enlarged, and an interstitial fibroid in the right side of the body of the organ. Extending to the left and posterior to the uterus was an oblong mass I estimated to be two inches long and an inch thick. This mass was soft and boggy and the uterine end began near the left corner. This I pronounced a pyosalpinx. Laparotomy was advised, but the patient positively refused to submit to any operative procedure. She had heard of the benefit of electricity in cases of fibroid tumors, and wanted it tried in her case. I explained to her that the presence of pus in the pelvis was considered a contra-indication to the use of electricity, but that some operators had beneficial results in treating pyosalpinx with electricity, and signified my willingness to use electricity in moderate doses, but would make no promises as to results. She accepted these conditions, and on February 1st the first application was made, a current of twenty-five milliampères' strength being employed five minutes, using Martin's abdominal electrode and Apostoli's intra-uterine electrode, the latter being connected with the negative pole of the battery. From this time to April 15th the patient had twelve applications of the current, the positive pole being attached to the intra-uterine electrode every time after the first. From twenty-five to fifty milliampères were used at first; once the strength of the current was sixty-five milliampères, and once, on account of the milliampèremeter failing to register, about one hundred and twenty-five milliampères were employed. This latter application caused considerable pain and produced cauterization of the tissues of the cervical and uterine canal. The pain lasted but a few hours, and then the patient was for several days easier than she had been for a long time. Following this strong application, weak ones were used until the superficial slough separated and the surface healed; then I tried a stronger current (sixty-five milliampères), but it induced so much pain and soreness that it was never repeated, but weaker ones were employed. On April 15th the patient moved away from the city, and I lost sight of the case until September 8th. The electricity had the effect of diminishing the amount of flow at menstruation, and at first caused a marked diminution in the size of the tumor. The purulent discharge continued about the same as when first seen.

On September 8th Mrs. P. came to the city to consult me. She stated that she had not menstruated for ten weeks, that her general health had improved somewhat, but that she still suffered considerable pain, and that the discharge of pus was quite profuse. By combined examination the uterus was found slightly movable. The abdominal walls were so lax and the vagina so large that the uterus could easily be grasped by the hands. It was larger than normal and the right side thicker, but one not knowing the previous history would hardly have suspected the presence of a myofibroma. A soft, boggy, oblong mass extended from the left horn of the uterus outward and slightly downward and backward. Thin creamy pus was seen oozing from the os. It was mopped away, and in a few minutes more made its appearance. The cervix and os looked healthy, except slightly macerated. The pus undoubtedly proceeded from the left tube. Here was a condition of affairs entirely new to me—a fibroid tumor undergoing absorption, atrophic metamorphosis of the uterus occurring, while a pyosalpinx was freely discharging into the uterine cavity.

Since the patient's condition was slowly improving, I concluded to keep hands off for a time, but explained the situation to the patient, and also the advisability of consulting a physician at once should the discharge cease suddenly, pain increase, and illness develop. I shall watch the further developments in this case with great interest.

Extended comment on these cases is unnecessary.

In Case I the pelvic abscess was coincident with abscesses in other parts of the pelvic and abdominal cavity and dependent upon the same cause—viz., peritonitis. There was no involvement of the tubes or ovaries in the suppurative process.

Cases II and V are interesting on account of their bearing upon the much-discussed question of the effects of electricity in diseases of the ovaries, tubes, and uterus. The suppuration in Case II was not, I think, due to septic infection.

The current had a caustic effect upon the endometrium, but the canal was always patulous, and every precaution we were acquainted with was used to prevent infection. The treatments were given at my office, but the patient took a long rest, rode home, and went to bed, remaining there the remainder of the day. The suppuration must have taken place slowly, for the patient was around the house continually and insisted that she was gradually improving. Menstruation occurred once before the rupture of the abscess and was nearly normal. The suppuration must have been due to the interpolar action of the current.

Case V tends to show that a pyosalpinx does not always contra-indicate the use of electricity. How great an effect the current had in effecting a diminution of the fibroid tumor I am unable to say. The apparent effect was to considerably lessen the size of the morbid growth. There was a profuse discharge of serum after each application of the current, so that it may have acted simply in the way of setting up a drainage of the tumor. I have observed in treating fibroid tumors by the Apostoli method that the decrease in the size of the tumor was greater when there was a copious serous discharge following each application. The amount of liquid draining away from one of these tumors when removed by hysterectomy is something surprising to one witnessing it for the first time.

In the application of the electrical currents of high intensity, if the negative pole be attached to the intra-uterine electrode, the transudation of serous liquid from the tumor into the uterine cavity will begin at once and continue for two or three days, and there will be usually at the beginning of the treatment a decrease in the size of the tumor in some degree corresponding to the amount of fluid transuded. This I believe to be the explanation of the fact that in nearly all cases in which this method is adopted the tumor will at first decrease in size, but, soon or late, a point is reached where the size of the tumor is unaffected by the passage of the current. It will explain, too, another fact: that in many instances very soon after the application of electricity is discontinued the tumor grows rapidly to its former dimensions. We can not find here, however, an explanation of all the interpolar changes induced when the electrical current is passed through tissues, for Case II shows us one instance in which suppuration was induced. Sometimes the growth of the tumor is permanently checked, and occasionally it is caused to disappear entirely. In our case, probably the changes incident to the menopause led to the gradual disappearance of the tumor.

Case III presents one point worthy of comment. The left tube was closed at both ends and distended to the point of bursting the thinnest point; the one ruptured in handling lay against and was adherent to the posterior layer of the broad ligament. In a brief time it would have ruptured and infectious inflammation of the broad ligament followed; then ulceration through the posterior layer of the broad ligament would have occurred. Soon would have followed the pouring of pus into the space between the folds of the ligament and a violent inflammation of all the tissues of that structure, and finally the formation of a large abscess rupturing into the vagina, rectum, or pelvic cavity.

Here is certainly indicated one of the ways in which pyosalpinx may lead to the formation of large abscesses and to general infection of the pelvic and abdominal cavities.

A CASE OF COMPOUND COMMINUTED FRACTURE OF THE PATELLA INTO THE KNEE JOINT.*

By M. T. SCOTT, M. D.,
LEXINGTON, KY.

On December 28, 1889, I was summoned four miles into the country to see W. C. P., aged thirty-seven, who gave the following history:

Two hours previous he was sitting on the front of a two-horse wagon, with legs flexed at right angles on the thighs. While in this position he struck the off horse of the team with a whip; the animal jumped forward, snapped the trace chain, and at the same time kicked viciously. The horse had on the previous day been rough shod, the calks on the hind shoes being very long and wedge-shaped. The calk struck the patient a quarter of an inch below the center of the right patella, causing a transverse wound half an inch wide.

The use of an aseptic probe revealed a puncture of the patella with comminution, together with a transverse fissure. Grasping the upper half with the fingers of one hand and the lower segment with the fingers of the other hand, a distinct but slight crepitation with motion was detected. There was, however, no material separation, as the periosteum was but slightly lacerated. The point of the heel of the shoe had penetrated the knee joint, as was shown by the passage of an aseptic probe three inches down in a vertical direction. Pressure over the lateral and posterior aspects of the joint forced out a considerable amount of bloody synovial fluid and air bubbles, the presence of air in the joint being due to the patient's attempts to walk and his endeavors to estimate the amount of injury immediately after its infliction.

Realizing that I had to deal with a compound, comminuted fracture of the patella, complicated by an open wound of the knee joint, I proceeded to treat the case on aseptic principles. The surrounding tissues were thoroughly cleansed. The external wound was enlarged half an inch. Small detached fragments of patella were removed with aseptic instruments. The joint was copiously flushed with bichloride solution, 1 to 3,000, until the fluid came away clear. No drainage was used. The external wound was closed with catgut and dressed with iodoform and bichloride gauze. A long, straight posterior splint was applied from the gluteal fold to the foot.

Twenty-four hours after the operation the pulse was 86 and the temperature 99°. The recovery was rapid and uneventful. At no time did the pulse run higher than 92 or the temperature rise above 99·5°. The wound healed kindly by the first intention without any suppuration whatever. A slight effusion into the joint was noticed at the first dressing, which was on the eighth day. This rapidly subsided and gave rise to no trouble. On the twenty-fourth day the splint was discarded and passive motion commenced. Seven weeks after the injury the patient reported at my office, walking with a cane. Extension was perfect and active flexion existed to a right angle. An adherent scar across the patella and a depression barely perceptible were the only sequelæ of the previous injury. Since then I have examined the joint and find all motions normal. No lameness.

In closing the report of this, which to me has been an interesting case, I would say that the patient was far from being a stout man and one in whom we should hope to see a vigorous display of that beautiful power which our forefathers were pleased to style the *vis medicatrix naturæ*. He was a sufferer from chronic diarrhœa with prolapsus recti. An inability to empty his bladder occasioned a constant dribbling of urine, which necessitated the use of a urinal. Chronic cystitis, the cause of which he refused to have investigated, occasioned ammoniacal urine, alkaline and foul smelling, which did not aid us in our endeavors to secure cleanliness and an aseptic condition.

* Read before the Mississippi Valley Medical Association at its sixteenth annual meeting.

The Eyes of Eye Surgeons.—"At the dinner of the Ophthalmological Section of the International Medical Congress at Berlin, Professor Hermann Cohn, of Breslau, showed a collection of autographs of the oculists who had taken part in the annual meetings at Heidelberg for twenty years, which was made specially interesting by the fact that opposite each name the signatory's visual power with the right and left eye respectively was indicated. Among other celebrities who figured in this list were Arlt, Horner, the elder Critchett, Schweigger, and Knapp. Among 44 oculists tested, visual acuity was normal in 32, over the normal in 10, and under it in 2. Twenty-eight, or 61 per cent., were short-sighted; the concave glasses required varied between Nos. 5 and 24, the average being 20, so that the myopia of the distinguished ophthalmologists in question was, as a rule, moderate in degree."—*British Medical Journal.*

THE

NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by D. APPLETON & Co. Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, NOVEMBER 8, 1890.

PASTEURISM BEFORE THE ACADEMY.

IT was really Pasteur's system of preventive inoculation that was under discussion at the New York Academy of Medicine on the evening of October 16th, although various aspects of the subject of rabies were made the theme of remarks, even the question of the existence of that disease. The few who have always maintained that there was no ground for regarding rabies as a disease *sui generis* seem to have been re-enforced to a certain extent by the carpers who assert that no such number of cases as recent reports have enumerated can possibly have occurred. The two classes together have been able to keep up enough opposition to the beneficent practice of antirabietic inoculation to breed some distrust of it among the public, and even to influence professional opinion against it in a measure, as is exemplified by the fact that many well-known medical journals have shown an inclination to discredit it. But what is there for the cavilers to stand on? To say that there is no such disease as rabies argues, to our mind, the possession of a child-like simplicity worthy of the votaries of "Christian science," or of those wiseacres who are fond of repeating, whenever dread of any epidemic disease is expressed, the vulgar dictum that a person is safe enough from pestilence if he is not afraid of it, ignoring the mortality caused by it among infants, who of course have no dread of disease. Little more worthy of consideration is the criticism that the number of cases of rabies reported since Pasteurism came into vogue is ridiculously out of proportion to the numbers reported in previous times. From no point of view could this objection be held to be cogent, for it does not touch the real question, but at most could only operate to discredit the reporters' accuracy. Perhaps rabies has been unusually prevalent in France during the past few years, but, if it has not, the great popular interest in it that has been brought about by the adoption of Pasteur's system may well have given rise to increased diligence in discovering and reporting the cases. We can not admit that the cases reported are so numerous as to preclude their being accounted for in this way. But, allowing that the figures are exaggerated, the admission proves only either that Pasteurism has not saved quite so many lives as the reports show, or else that the figures have been falsified purposely or ignorantly, and therefore that their promulgators are open to the verdict *falsus in uno, falsus in omne*. This last is probably what is sought to be implied, but the implication may well be disregarded by Pasteur and his associates. The results of their inoculations are in no wise influenced by the degree of their accuracy or honesty in collecting statistics. The plain fact remains that hundreds of persons bitten by animals unquestionably rabid have escaped the disease. It will not do to say that only a certain percentage of such persons are infected, for nothing like that percentage of infection has obtained among the exposed persons on whom Pasteurism has been tried.

This expresses what we have maintained ever since the practice was begun, but its opponents have been persistent and talkative, and we confess to much gratification at the general drift of what was said at the Academy's meeting. In particular, it strikes us that Dr. Dana's paper on The Reality of Rabies shows such a spirit of fairness and such close reasoning as must go far to silence the last sputter of incredulity, or as would, at least, if men were influenced more by reason and less by prejudice or an innate propensity to oppose whatever is new. Unfortunately, doctrines that tend to overturn established dogmas and practices always have to contend against very much the same kind and degree of opposition, but they invariably become established on a basis all the more solid, and it is therefore not a matter for unmitigated regret that Pasteurism has had to encounter the same obstacles.

THE NEW YORK STATE MEDICAL ASSOCIATION.

IT is now seven years since this organization was started. It owed its origin to an irreconcilable disagreement between its founders and their fellow-members of the Medical Society of the State of New York—a disagreement having reference solely to ethical declarations. The division was a matter of regret at the time, and certainly it entailed upon the physicians of the State a weakening of their influence in a corporate capacity. In no other way, however, has it proved injurious; as regards scientific work, it has been in a high degree beneficial. Both societies have constantly issued programmes overflowing with titles of important contributions by men high in the esteem of their fellows. There is no enmity between them, but only a wholesome emulation. The State is large and populous, and perhaps it is best that it should have two medical societies, for meetings much larger than each of them now holds would probably prove unwieldy. This would breed apathy, and stagnation would be in danger of following.

The new association has unquestionably been well managed. We have always held that it had a great advantage in the fact that it held all its meetings in New York. This advantage is now supplemented by its acquirement of permanent quarters for its library and for other purposes. There is something tangible about an organization occupying a building of its own. Perhaps another advantage is to be found in its district branches, holding meetings at various times during the year and having a closer connection with the association than the county societies have with the old organization. Moreover, the pride of the members must have been stimulated by the handsome and well-edited annual volumes of transactions published by the association. It will be seen that there is no dearth of conceivable reasons for the prosperity and creditable career of the association, the existence of which, whatever the

real reasons may have been, is beyond question. The meetings are of benefit not alone to the members, but in a very high degree to the profession at large in the city, many of whom either attend them or read the published reports; and this benefit can hardly fail to be decidedly enhanced by the establishment of a permanent home for the association.

MINOR PARAGRAPHS.

THE SPECIFIC PATHOLOGY OF CANCER.

A recent number of the *Proceedings of the Royal Society* contains an article by Dr. C. A. Ballance and Dr. S. G. Shattock on experimental investigations into the pathology of cancer. Their object was to find out if any special micro-organisms could be cultivated from malignant tumors, as had been done from tubercle and the pathological formations of certain other infective diseases. The experiments were made with three lipomata, one myxoma, three sarcomata, and about thirty carcinomata. The results obtained, both in the cultivation and in the transplantation, were entirely *nil*. Notwithstanding such results, the authors did not think the evidence from analogy that cancer was probably micro-parasitic in origin was entirely overthrown, but that it was possible that the micro-organism of cancer did not belong to the *Protophyta*, but to the *Protozoa*, in which case the difficulty of artificial culture would be easily explained; and the enormous rapidity of cell growth in cancer might be thought of as being induced by a cancerous rejuvenescence setting in as a consequence of the conjugation of the "parasite" with the cell of the normal tissue. The authors had conducted some of their experiments with human blood-serum, but no growth had occurred under sterile conditions, either when the serum had been simply inoculated or when a piece of living cancer tissue had been placed in or upon it.

MICROSCOPICAL STUDIES OF THE BRAIN.

Dr. C. E. Breevor, in the *Proceedings of the Royal Society*, gives the results of some investigations on the course of the fibers of the cingulum, of the posterior parts of the corpus callosum, and of the fornix in the marmoset monkey. The horizontal part of the cingulum was found to consist, not of fibers extending throughout its whole length, but of internuncial fibers coursing between the gyrus fornicatus and the centrum ovale; the anterior part connecting the olfactory nerve with the frontal region, the posterior part containing internuncial fibers between the hippocampi and the inferior surface of the temporo-sphenoidal lobe. Broca's conclusion, that the cingulum was connected with the hippocampal lobule and its contained nucleus, was not confirmed in the present investigation. The superficial fibers of the gyrus fornicatus were found to be a separate tract, and not part of the cingulum. No connection between the fibers of the posterior parts of the corpus callosum and those of the internal capsule, as described by Hamilton, could be found. The median part was traced horizontally backward into the septum between the body and the splenium of the corpus callosum, but was not found to join the cingulum, as had been described by Meynert.

BONE-GRAFTING FROM THE DOG.

On the 15th of October, at the Post-graduate Medical School and Hospital, Dr. A. M. Phelps performed at his clinic the operation of transplanting a large section of the fore leg of a dog into the tibia of a patient suffering from an ununited fracture with bad deformity. The patient had been operated on twice, and all means employed had failed. A medium-sized dog was selected and carefully prepared for the operation. The dog's elbow was excised, and its leg amputated so as to leave a piece of bone long enough to fill in the space between the denuded ends of the patient's tibia. The dog was then lashed to the patient's leg with a plaster-of-Paris bandage, and the bone graft securely wired into the patient's tibia. It was expected that by this procedure the dog's brachial artery would keep up the nutrition of the transplanted part and furnish the material for new bone, which the patient seemed incapable of producing. Dr. Phelps will soon furnish the details of the operation for publication in the Journal.

THE NEW VOLUME OF THE INDEX-CATALOGUE.

The eleventh volume of the *Index-Catalogue of the Library of the Surgeon-General's Office, United States Army*, has just been issued. It contains the fourth addition to the alphabetical list of abbreviations of titles of medical periodicals, and carries the vocabulary from Phædronus to Régent. The work, it will be seen, is nearing its end. When its publication was begun the fear was entertained, not unnaturally, that one man's lifetime would hardly suffice for its completion, but such a foreboding may now be regarded as practically dispelled; Dr. Billings is still in the prime of life and will yet be at the height of his powers when he gives us the concluding volume. If the medical profession needed any reminder of the immense service he has performed for its literature, each of the volumes as it appears would serve the purpose amply.

PRECAUTIONS AGAINST LUNATICS.

It is to be hoped that the late Dr. Lloyd did not die in vain. The Grand Jury of Kings County has censured the State Commission in Lunacy for countenancing the practice in asylums of registering patients as "discharged" when they have escaped. It has also censured the officials of the Kings County Insane Asylum for the laxity displayed in the case of the lunatic who killed Dr. Lloyd, and recommended the employment of a police force in the asylum.

AN ISLAND FOR INEBRIATES.

At the Berlin Congress Dr. Karl Kahlbaum stated that one very serious error had often been made in the treatment of inebriety, namely, that the patient was not kept long enough under observation to make sure of his real cure. Improvement was too often mistaken for and reported as cure. He proposed that the Government should set apart an island for dipsomaniacs solely.

SIGNOR SUCCI.

This gentleman, who has entertained the residents of several European cities—or at least secured a portion of their attention—by prolonged abstinence from food, is now in New York, and is advertised to fast for forty-five days. Just what there is about such a performance to attract spectators we shall not undertake to say, but we do not doubt that there is something.

THE NEW YORK ACADEMY OF MEDICINE.

The programme for the meeting on Thursday evening of this week consisted of reports of so-called "delegates" to the Tenth International Medical Congress—eleven in number. It

is well known that these congresses are not made up of delegates. It was therefore a work of supererogation for the Academy to appoint them, and to devote a meeting to their "reports" seems to us to argue such a lack of legitimate material as ought not to be encountered at this time of the year.

THE BALTIMORE MEDICAL AND SURGICAL RECORD.

This is the title of a new monthly journal, owned and edited by Dr. T. H. Graham. The first number, for October, contains forty-two pages of reading matter, and is embellished with an excellent portrait of a well-known physician of Baltimore, Dr. H. P. C. Wilson. The number includes articles by Dr. E. S. McKee, of Cincinnati, and Dr. Frank West, Dr. W. J. Jones, Dr. William B. Canfield, and Dr. George H. Rohé, of Baltimore.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending November 3, 1890:

DISEASES.	Week ending Oct. 28.		Week ending Nov. 3.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	37	7	25	6
Scarlet fever	42	1	39	1
Cerebro-spinal meningitis	0	0	2	1
Measles	82	6	97	6
Diphtheria	67	21	54	17
Varicella	1	0	5	0

A Death during Etherization occurred at the Brooklyn City Hospital on October 29th. The patient, who was about to undergo an operation for necrosis of one of the bones of the foot, had been sick for a long time, but a careful cardiac examination before the operation was decided upon showed no contra-indication to etherization. About four drachms only of the ether had been administered when respiration suddenly ceased, and a few seconds later the heart's action became imperceptible. Approved means of resuscitation were diligently employed by the house staff for two hours, but without avail.

The Medical Colleges of Baltimore.—The *Baltimore Medical and Surgical Record* announces that the new building of the College of Physicians and Surgeons will be ready for the coming term, and that the class is a large one. The same journal states that a story has been added to the building of the Baltimore Medical College, with fully equipped laboratories and a well-arranged dissecting room.

The Death of Dr. Gustave Monod, of Paris, formerly a professor of the Faculty of Medicine, is announced as having taken place on the 21st of October. He was eighty-six years old.

The New York Academy of Medicine.—At the next meeting of the Section in Pædiatrics, on Thursday evening, the 13th inst., Dr. Walter Mendelson will read A Note on How to obtain the Best Practical Results with a Milk-sterilizer, and Dr. J. Lewis Smith a paper on Peritonitis in Infancy and Childhood.

Dr. C. Eugene Riggs, of St. Paul, Minn., a commissioner in lunacy of that State, was given a reception last Saturday evening at the house of Dr. Landon Carter Gray, of New York.

The American Academy of Medicine will hold its annual meeting in Philadelphia on Wednesday and Thursday, December 3d and 4th.

The Harlem Medical Association.—The programme for the second regular meeting, on Wednesday evening, the 5th inst., included the presentation of patients by Dr. J. G. Truax and Dr. E. Fridenberg, the presentation of a ruptured ectopic gestation sac by Dr. T. H. Manley, and the reading of a paper on Ectopic Gestation by Dr. F. H. Daniels.

Changes of Address.—Dr. Alexander Duane, to No. 11 East Thirtieth Street; Dr. Max Einhorn, to No. 120 East Sixty-fourth Street; Dr. William J. Morton, to No. 19 East Twenty-eighth Street.

The Death of Professor von Nussbaum, of the University of Munich, occurred on the 31st of October. The deceased was sixty-one years old. He is reported to have been ill for the past year as the result of an attack of influenza.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 26 to November 1, 1890:*

Cowrey, Stevens G., Surgeon, is granted leave of absence for one month, with permission to apply for an extension of fifteen days, to take effect upon the arrival of Acting Assistant Surgeon A. P. Frick at Fort Marey. Par. 2, S. O. 112, Department of Arizona, Los Angeles, Cal., October 24, 1890.

By direction of the Secretary of War, the following changes in the stations of officers of the medical department are ordered:

Woodruff, Charles E., First Lieutenant and Assistant Surgeon, is relieved from duty at Fort Gibson, California, and will report in person to the commanding officer, Fort Missoula, Montana, for duty at that post, relieving De Witt, Calvin, Major and Surgeon. Major De Witt, upon being so relieved, will report in person to the commanding officer, Fort Hancock, Texas, for duty at that post. Par. 6, S. O. 249, A. G. O., Washington, D. C., October 24, 1890.

Ewing, Charles B., Captain and Assistant Surgeon. By direction of the Secretary of War the leave of absence granted in S. O. 131, September 22, 1890, Department of the Missouri, is extended fourteen days. S. O. 250, A. G. O., October 25, 1890.

Edie, Guy L., Captain and Assistant Surgeon, is granted leave of absence for one month, on surgeon's certificate of disability, Fort Douglas, Utah. S. O. 80, Headquarters Department of the Platte, Omaha, Nebraska, October 27, 1890.

Wales, Philip G., First Lieutenant and Assistant Surgeon, is relieved from station and further duty at Fort Huachuca, Arizona Territory, and assigned to duty at San Carlos, Arizona Territory, where he is now temporarily serving. Par. 13, S. O. 254, A. G. O., October 30, 1890.

So much of Paragraph 2, S. O. 208, A. G. O., September 5, 1890, as directs Jarvis, Nathan S., First Lieutenant and Assistant Surgeon, to report for duty at San Carlos, Arizona Territory, is revoked. On the expiration of his present sick leave of absence, Lieutenant Jarvis will report in person to the commanding officer, Fort Bayard, New Mexico, for duty at that station. Par. 13, S. O. 254, A. G. O., October 30, 1890.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending November 1, 1890:*

Stephenson, F. B., Surgeon. Detached from the Receiving-ship Wabash and to wait orders.

Martin, H. M., Surgeon. Ordered to the Receiving-ship Wabash.

Stone, Lewis H., Assistant Surgeon. Ordered to the U. S. Steamer Pinta.

Arnold, William F., Assistant Surgeon. Detached from the U. S. Steamer Pinta and granted two months' leave.

Owens, Thomas, Surgeon. Detached from the Coast Survey Steamer Blake and to wait orders.

Blackwood, N. J., Assistant Surgeon. Ordered to the Receiving-ship Vermont.

Bogert, E. S., Assistant Surgeon. Detached from the U. S. Receiving-ship Vermont and ordered to the Coast Survey Steamer Blake.

Moore, A. M., Surgeon. Detached from the U. S. Steamer Kearsarge and ordered to the Naval Hospital, Mare Island, Cal.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service from October 6, 1890, to October 25, 1890:*

Hutton, W. H. H., Surgeon. Detailed as chairman, Board of Examiners, revoked; ordered to Washington, D. C., for temporary duty. October 14, 1890.

Wyman, Walter, Surgeon. To inspect quarantine stations. October 14, 1890.

Long, W. H., Surgeon. Detailed as chairman, Board of Examiners. October 14, 1890.

Sawtelle, H. W., Surgeon. Granted leave of absence for five days. October 13, 1890.

Gassaway, J. M., Surgeon. Granted leave of absence for thirty days. October 11, 1890.

Irwin, Fairfax, Surgeon. Detailed as recorder, Board of Examiners. October 14, 1890.

Ames, R. P. M., Passed Assistant Surgeon. Granted leave of absence for thirty days. October 14, 1890.

White, J. H., Passed Assistant Surgeon. Granted leave of absence for thirty days. October 24, 1890.

Pettus, W. J., Passed Assistant Surgeon. To proceed to Vineyard Haven, Mass., for temporary duty. October 9, 1890.

Perry, T. B., Assistant Surgeon. Ordered to examination for promotion. October 9, 1890.

Kinyoun, J. J., Assistant Surgeon. Ordered to examination for promotion. October 10, 1890.

Condict, A. W., Assistant Surgeon. To proceed to Baltimore, Md., for temporary duty. October 18, 1890.

Resignation.

Ames, R. P. M., Passed Assistant Surgeon. Resignation accepted by the President, to take effect November 15, 1890. October 14, 1890.

Society Meetings for the Coming Week:

Monday, *November 10th:* New York Academy of Medicine (Section in Surgery); New York Ophthalmological Society (private); New York Medico-historical Society (private); Lenox Medical and Surgical Society (private); New York Academy of Sciences (Section in Chemistry and Technology); Boston Society for Medical Improvement; Gynæcological Society of Boston; Burlington, Vt, Medical and Surgical Club (annual); Norwalk, Conn., Medical Society (private); Baltimore Medical Association.

Tuesday, *November 11th:* New York Medical Union (private); Medical Society of the County of Rensselaer, N. Y.; Norfolk, Mass., District Medical Society (Hyde Park); Newark, N. J., and Trenton (private), N. J., Medical Associations; Camden, N. J., County Medical Society (semi-annual—Camden); Baltimore Gynæcological and Obstetrical Society; Southern Surgical and Gynæcological Association (first day—Atlanta, Ga.).

Wednesday, *November 12th:* New York Surgical Society; New York Pathological Society; American Microscopical Society of the City of New York; Medical Society of the County of Albany; Pittsfield, Mass., Medical Association (private); Worcester, Mass., District Medical Society (Worcester); Philadelphia County Medical Society; Southern Surgical and Gynæcological Association (second day).

Thursday, *November 13th:* New York Academy of Medicine (Section in Pædriatics); Society of Medical Jurisprudence and State Medicine; New York Physicians' Mutual Aid Association (annual); Brooklyn Pathological Society; Medical Society of the County of Cayuga; South Boston, Mass., Medical Club (private—annual); Pathological Society of Philadelphia; Southern Surgical and Gynæcological Association (third day).

Friday, *November 14th:* Yorkville Medical Association (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties.

Saturday, *November 15th:* Clinical Society of the New York Postgraduate Medical School and Hospital.

Letters to the Editor.

THE SLUR ON THE POLYCLINIC.

267 Madison Avenue, *October 31, 1890.*

To the Editor of the New York Medical Journal:

Sir: I am sure every member of the staff of teachers at the Polyclinic will appreciate the publicity you have, in your issue of last week, given to the "correction of a slur" on this institution.

The *New York Times* on October 11th, as a part of the obituary notice of a most excellent man, a minister of the gospel, respected and loved by all who knew him, so far forgot the dignity and sense of propriety which usually characterize this paper as to include the gratuitous falsehood that death was "from the effect of an amputation of the hip performed in the New York Polyclinic and pronounced at the time to be 'highly successful.'"

I at once wrote the editor asking from what source he had obtained this information. He replied that the notice "was written in this office upon information which I am disposed to believe is thoroughly reliable." To my further inquiry, asking that if I would prove his information to be absolutely false, he would publish a correction as prominently as was published the misstatement, I received no reply.

A day or two later appeared the manly letter from the dead man's father, printed under the title of An Impression Corrected. This letter gave not only the testimony of the father, but of three well-known practitioners in Alabama, who had seen the patient just before his death, that the fatal termination was in no way due to the operation performed eight months before. Dr. J. T. Searcy, of Tuscaloosa, one of the most prominent physicians of Alabama, in answer to my inquiry as to the cause of death, writes: "The operation was a perfect success. The stump was in a perfectly healthy condition at the time of his death. There was no return of the sarcoma in the field of operation or anywhere else in his body. He died of miliary tuberculosis. His consumption was very rapid toward the last."

This case attracted considerable attention, as it was the first one in which my *bloodless method* was employed.

John A. Wyeth, M. D.

THE TREATMENT OF ABORTION.

Seaton, Ill., *October 14, 1890.*

To the Editor of the New York Medical Journal:

Sir: Dr. T. Gaillard Thomas, in a clinical lecture recently, published in the *Annals of Gynæcology and Pædiatry*, and quoted in *The Therapeutic Analyst*, said: "When called upon to attend a case of abortion, there is one of two things that you will have to decide upon at once—whether you can prevent the abortion, and if you can not do this, how to conduct it judiciously to a termination. . . .

"We will assume in this case that the abortion can not be prevented. Under such circumstances it is no more right to stop its pains than it is right to stop the pains of labor at full term. . . .

"We have in abortion hæmorrhage usually going on all the time. I want to give you a remedy for this hæmorrhage, when it becomes severe—a method by which it can be controlled at once.

"This one remedy is the tampon. This is the one great remedy for this condition. One great danger in abortion is hæmorrhage, and the indication is to stop that hæmorrhage. This is the one and only indication to be fulfilled in the beginning, and when you have done this thoroughly you have done your whole duty to your patient."

He then gives a very thorough and effective method of tamponing, and proceeds:

"After some hours, from twelve to twenty-four, take out the tampon, being guided in this by the pain of the patient, and you will then, in the majority of cases, have brought the abortion to a successful termination."

This is no doubt classical and efficient, and sufficiently dog-

matical. I would not criticise it as one method of treating abortion; but it is not the only method, nor, to my mind, is it the best way. I will report my method.

When called to a case of unpreventable abortion, after proper purification I proceed at once to rid the vagina of clots. I next make a digital examination of the os uteri, and if, as is frequently the case, I find the products of conception presenting at the external os, I bring them away with the finger.

If they are not presenting at the external os, or, if presenting, only a part comes away, I thrust my forefinger through the cervical canal into the cavity of the womb. I next bring the womb forward if necessary with the finger in it, and with the other hand steady the uterus and make pressure downward. I then proceed to disengage the placenta. Having done so, I bring away, with the finger, all the products of conception, and rid the vagina of any remaining clots, and the case is terminated.

In order to reach the fundus with the finger it is often necessary to push the hand entirely inside the vagina. This I have never had any great difficulty in doing. After the hand has passed into the pelvic cavity, there is no special complaint of discomfort.

I now give half a teaspoonful of Squibb's fluid extract of ergot, and direct it to be given in twenty-drop doses every four hours, or more frequently if necessary to control hæmorrhage, for twenty-four or forty-eight hours.

I next impress upon the patient's mind the importance of keeping quiet in bed for a week or ten days, direct her to keep her person and bed scrupulously clean, to keep her bowels open with mild laxatives, to sit on the chamber when passing urine, and to take her accustomed food.

In conclusion, what may be said of this method?

1. It is sufficiently simple.

2. It is not very difficult.

3. I have found no great difficulty in passing the finger into the uterus at the fifth or sixth week of pregnancy.

4. It is the best method of arresting the hæmorrhage; it ceases or becomes practically harmless as soon as the finger has passed the cervix, especially if the finger fits the cervical canal tightly.

5. It saves the woman the hours of exquisite suffering of the uterine contractions and the blood-pressure of the tampon.

6. It terminates the case in about the time it would take to make ready the tampon.

7. In a fair experience of over twenty-two years I have not met with a case in which it failed, or a case in which there were after-complications. THOMAS A. ELDER, M. D.

DR. GIBIER'S THEORY OF TEMPERAMENTS.

111 WARWICK STREET, BROOKLYN, *October 22, 1890.*

To the Editor of the New York Medical Journal:

SIR: On reading the article of Dr. Paul Gibier, on A New Theory about Temperaments, in the Journal for October 18, 1890, it occurred to my mind that the well-known therapeutico-chemical fact—namely, that acids check acid secretions and increase alkaline secretions, also the reverse—played an important rôle here.

1. As it is in the alkaline subjects that tuberculosis is common, not in the acid subjects.

2. It requires alkalinity to favor the growth of the tubercle bacillus; acids even diluted to thousandths will destroy it.

3. Children of tubercular parents are oftentimes healthy through life and show no disposition to develop tuberculosis, but the children of these again are tubercular without cause, except the diathesis.

4. Has not the temperament, if taken according to the theory of Gibier, something to do with the development of tuberculosis in alternate generations? Say, first, alkaline parents have acid children and the reverse in a tubercular generation, whereas an acid and an alkaline parent have neutral children.

5. Could not tuberculosis lie dormant in persons, and when the opportunity of acid or equal temperaments or acid tubercular parents arrives, produce alkaline or tubercular children?

The same may be said of other diseases.

Will some one with a wider range of experience than myself give this further investigation if he thinks it worth while, for the benefit of medical men and sanitarians as well as the tubercular race or generation? C. A. VON UREF, M. D.

Proceedings of Societies.

NEW YORK STATE MEDICAL ASSOCIATION.

Seventh Annual Meeting, held at the Mott Memorial Hall, New York, October 22, 23, and 24, 1890.

The President, Dr. JOHN G. ORTON, of Binghamton, in the Chair.

THE Chairman of the Committee of Arrangements, Dr. J. G. TRUAX, in his report formally welcomed the association to its occupation of a new home and library at the Mott Memorial Hall, recently acquired for permanent use.

The Report of the Secretary contained pointed reference to the New York State Medical Examination Bill, which had recently become law. He stated that every pressure, by argument and remonstrance, had been brought to bear upon the Governor to withhold his signature, upon the ground that the bill had not been duly considered in the Senate and that its clauses were unjust and one-sided. The tenor of the reply to this appeal was that the Governor must assume the bill to have been duly considered in committee, and that if exception was taken to it another bill in modification could be sent up next year.

The President's Address.—The PRESIDENT congratulated the association on having at last acquired a home for its members and its library. He then considered at some length the question of educational preparation for the profession. He said that while upholding the principle that medical colleges should demand proof of adequate preliminary education from would-be medical students, he was not prepared to go so far as to say that the possession of academic degrees should be demanded as a *sine qua non* of qualification for entering upon a medical course. He did not believe that the colleges of this country were below par. There was every evidence that they were steadily raising the standard of excellence in the educational pabulum. They were really better adapted to the requirements than those of the old country. The unfortunate phase of the situation was that the colleges had not shut their doors against inadequately prepared students. The speaker then paid unqualified tribute to the value of medical journals, which he said had assumed a proportion and weight of character unequaled in any other branch of science or art. To-day a subscription to a reliable medical journal was an investment which would repay with interest many times compounded. He advocated the establishment of local boards of sanitation, the business of which should be to formulate principles of sanitary science for the people, for publication in the secular press, which would enable them to intelligently guard against preventable disease.

Prognostics in Medicine.—Dr. John Cronyn, of Erie County, read a paper on this subject. In the course of an extended review of points for prognosis he touched upon the question of treatment. He thought that prognosis in cases of apoplexy could now hardly be as favorable as when bloodletting was more in vogue. Pneumonia was not as low in the mortality tables as the vaunted progress in medical science would seem to warrant.

New Method of Treatment for Retro-displacements of the Uterus with Adhesions.—Dr. A. P. Dudley, of New York County, described his present method of surgical treatment for certain forms of the above condition. After a review of the various methods for correcting this lesion recently in vogue, he narrated the details of his operative procedure in a case of diseased ovaries and tubes. He opened the abdomen, broke up the adhesions about the uterus, and then taking the left ovary and tube, he drew them up through the abdominal incision and saw that the fimbriated extremity was open. He then took a piece of No. 27 silver wire, slightly pointed at one end, which he gently passed through the entire length of the tube, demonstrating it as pervious. The ovary, which contained several cysts, was then tapped with a spear pointed needle by passing the needle directly through the organ and squeezing the water out. The sacs were then allowed to fill with fresh blood. The tube and ovary were dropped back and the right side was treated in the same manner. An assistant then placed two fingers in the vagina and lifted the uterus as high as possible in the pelvis. The operator was thus enabled to bring the uterus close up to the abdominal incision. With a pair of delicate scissors he then denuded the peritonæum from the anterior wall of the uterus, the surface thus freshened being of an oval shape. Care was taken not to go too near the bladder. Then each round ligament was brought up and a portion of the peritoneal covering upon the inner side denuded to correspond with that upon the uterus. With a continuous suture of catgut he then sewed these denuded surfaces together. The sutures were passed deep enough to secure against their cutting out before union took place. The uterus was then dropped back, and the traction upon the round ligaments immediately drew the organ into a position of anteversion, the sutured surfaces lying in apposition to the posterior surface of the bladder. He did not introduce a pessary, preferring to allow the work to rest upon its merits. The advantages of this operation were threefold: 1. It shortened the round ligaments, without sacrificing any part of them, sufficiently to hold the uterus in a position anterior to the perpendicular line of the body. 2. Denuding and firmly fastening the round ligament to the anterior surface of the uterus thickened and gave extra support to the latter. 3. The uterus was maintained in a normal position without fastening any of it to the anterior abdominal wall, a position which he thought Nature never intended it to occupy.

This operation the speaker maintained presented the following advantages over hysterorrhaphy or Alexander's operation: 1. It corrected the displacements by utilizing the natural supports of the uterus without sacrificing any of them. 2. The proper diaphragmatic action of the pelvic floor was not interfered with. 3. The bladder was not imprisoned and its proper action was undisturbed. 4. There was no chance for intestinal adhesion about the line of suture, for the latter lay in apposition to the posterior surface of the bladder, and adhesion taking place at this point simply elongated the utero-vesical junction. 5. In case of impregnation, the uterus was free to rise in the abdominal cavity naturally. 6. The use of the catgut suture did away with the danger of the formation of sinuses by the ligature. One of his objects in performing this operation had been to save the ovaries, for he had come to believe that more was taken out than should be. He had operated in the manner described four times, and he thought this was enough to demonstrate that it was possible to attack the cysts in the ovaries and still not have any trouble in the tubes and ovaries after the laparotomy.

Discussion on Intracranial Lesions.—This subject was considered by various speakers under the following subdivisions:

The present means of localizing intracranial lesions.

The nature of the chief intracranial lesions (hæmorrhage, abscesses, tumors), and how can they be discriminated.

The indications and contra-indications of operative interference in cases of intracranial lesions.

The best modes of operating in cases of intracranial lesions.

The immediate and also the remote results of operative treatment in cases of intracranial lesions.

Dr. W. W. Keen, of Pennsylvania, prefaced his remarks by the exhibition and description of a new Rolandic-fissure meter, with radiating arm and index built after the manner of the cyrtometer, and the design of Horsley, of England. The indications for operative treatment in brain lesions, he said, should be based on careful observation of the peculiar physical characteristics, the mechanical depressions, and functional disturbances.

In the course of an elaborate survey of the whole clinical aspect of the subject from an operator's point of view the speaker emphasized his opinion that if a lesion could be located and distinguished from other conditions which might produce more or less similar phenomena, and if the general clinical indications were such as pointed to the necessity for operative treatment, then it was the duty of the competent surgeon to open the head. The head had been too long regarded as something apart and different from other portions of the body, and he would urge that it should be made to fall into line with other cavities, subject, as it was, to the same diseases and injuries. The methods of treatment might require modification in detail, but should be the same in principle.

Dr. J. J. Putnam, of Boston, drew attention to the relative value of certain so-called localizing signs of cerebral tumors, especially such tumors as lay a little outside the familiar areas of the central, temporal, and occipital zones, and only impinging upon them, so that the symptoms to which they gave rise would be liable to occur rather late in the progress of the case. There were cases which, obviously for more reasons than one, were relatively unsuited for surgical treatment. It was generally admitted as a clinical principle that the monoplegias and localized paralyses were more valuable as localizing signs than the monospasm or localized convulsions. Those functions of the brain which were relatively of a highly specialized and complex character were more likely to suffer disturbance than the less highly specialized and complex or more fundamental functions. There must be few tumor operations in which the convolutions near the growth were not found more or less displaced, and often they were broadened to twice their natural size or flattened to the thickness of cardboard. There were cases, however, where this error was of importance—those, namely, where convolutions were excited by pressure transmitted from a considerable distance, or by œdema and anæmia. This had occurred in a case of the author's. Unilateral neuritis had been held as being significant in indicating the pressure of a tumor of the opposite side of the brain. But the reverse of this condition was true in the author's case of tumor of the middle frontal convolution, so that this sign was really of very little value. No one interested in cerebral localization could have failed to notice the experiences of Schaeffer and Mauk in showing that infinite movements of the eyes and the eyelids were represented in the posterior limb of the angular gyrus and in the occipital lobes, the connecting tracts reaching

the ocnlo-motor nuclei not indirectly through the Rolandic area, bnt by direct paths.

Dr. J. B. Roberts, of Philadelphia, thought that, thongh many lives had undoubtedly been saved by judicious surgery about the head after fractures, still the impulse given to rush into operations in this region had done a great deal of harm. He was glad that the pendulum was swinging the other way. Traumatic cases offered the best prospect of good resnlts, and probably many patients died who conld have been saved by timely operative interference.

Dr. C. K. Mills, of Philadelphia, said the canses of failnre in the present method of localizing intracranial lesions were due to a variety of circumstances, and might conveniently be arranged into several classes. First, by giving too mnch weight to certain classes of symptoms, which were regarded as determinative of the site of the lesion, as, for example, the so-called signal or initial symptoms; second, by considering only symptoms of late invasion, as in the case of lesions growing from latent to active areas; third, by giving relatively too much importance to motor localizing symptoms; fonrth, by overlooking multiple or diffnsed lesions; fifth, by operating for incurable cases of arrested development. The so-called signal or initial symptom, while of great value, had proved sometimes a misleading light. The motor signal symptom had been made use of in a large nnmber of cases to guide the surgeon, sometimes successfully, but, the author was almost inclined to say, almost as often not so. It must be remembered that in every case of nnilateral or monospasm, whether reflex, dnral, nephritic, toxic, or hysterical, the spasm really or apparently began with an initial symptom in the limb or face. This might indicate that the beginning of the cerebral discharge occnrred in the area of the cortex, which was the seat of the representation of the movement, but it would be nnwise to operate with such indications. Occasionally conjugate deviation of the eyes and head had been used as a guide to operative procedure. This was one of the errors into which a thoughtless or badly informed neurologist might sometimes be led. In making a diagnosis as to the existence of hæmorrhage, we must depend more largely upon general symptoms. What was true of tnmor in this respect was still more strikingly trne of abscess. A number of mistakes had been made in cases of trephining for tumor or abscess by the operator being guided too much by motor symptoms, which were really the result of the diffusion of the lesion to the motor areas. In the analysis of the symptoms with a view of deciding as to operation, too much stress was sometimes placed npon motor symptoms, particularly on more or less circumscribed spasmodic manifestations. In not a few cases of cerebral abscess, sensory or special symptoms might decide in favor of operating, and at the same time might not properly guide to the seat of operation. All active localized symptoms of the brain, the result of mastoid or anral disease, nnless it was word-deafness and left-sided affections, were the resnlt of the extension of the pnrulent process. Several mistakes had been made in cases in which large lesions, either in the frontal or temporal lobe, had caused prominent motor symptoms by pressure either upon the motor tracts in the capsnle or upon the cortical areas of these tracts. In one case of this kind the symptoms all pointed to brachial crural monoplegia, due to tnmor and intercurrent hæmorrhage. The autopsy showed a tumor, with large hæmorrhage in the right temporal lobe, and strictly confined to this lobe, but evidently causing great pressure. Several recorded failures had been the result of overlooking the pressnre of multiple or diffused lesions. Operating in cases of tubercular disease of the brain vessels or membranes had also been another source of error and cause of failnre. It was an error, at least in the majority of cases, to operate guided by certain localizing phenomena of the spastic and paralytic, congenital and early infantile affections.

A careful review of the surgical operations guided by localization rule, in whole or part, showed that probably the greatest success during the last few years had been trephining for endocranial hæmorrhage. Occasional failure had resulted in traumatic cases, and for several reasons. In the first place, the fact was not fully considered that, in many cases of depressed or non-depressed fractures, hæmorrhages took place not only at or in direct connection with the place of injnry, bnt also at varions positions more or less remote.

Dr. J. D. Bryant, of New York County, in considering the question as to the present means of localizing intracranial lesions, limited the term lesion to abscess, hæmorrhage, depressed bone, and tnmors of intracranial origin. The present means of localizing these lesions conld be classified for convenience' sake as topographical, physiological, and instrumental. The topographical related to the connection existing between certain established landmarks and lines of the cranium that were found to bear a decided relationship to superficial parts of the encephalon, many of which parts had had definite functions assigned to them already. The physiological means related to the establishment of the site of a pathological process by studying the derivation of the function of a part from the normal, as the result of a local disease or injury. The instrnmental means were largely subsidiary and their application was often more of an experimental than of a practical character. The speaker then further dealt with the question by the recitation of cases having direct bearing on the subject. Among the most important deductions were: 1. That a small and presumptively circumscribed injnry of the brain substance at the upper end of the fissure of Rolando might incite an advancing cerebral disintegration sufficient to involve the motor centers associated with this fissure without causing notable constitutional symptoms. 2. That aspiration of the brain as a means of diagnosticating the existence or the situation of an abscess was of uncertain utility, even when a fair-sized needle was used, and that the employment of the ordinary hypodermic appliances for this purpose was entirely unreliable and misleading. 3. That extensive fissnre could begin at some distance from the violence causing it, and that its existence might remain nnrecognized without an extended exploration. 4. That extensive and fatal vascnlar complications might be caused at a considerable distance from the seat of an apparently innocent injury of the scalp or skull. 5. That where paralysis, involving the motor areas of the brain, followed an apparently trivial injury of the head, an operation at the seat of the areas was indicated for the purpose of exploration alone. 6. That the removal of a compressed brain clot was not necessarily followed by improvement of the symptoms of compression, and that if the brain did not soon resume the normal relation with the skull, death would ensue as the result. In another of the cases cited the patient had, immediately after being hit over the head with a bottle, lost the power of speaking his own name, but had been able to write it and the name of his assailant on paper. When admitted to the hospital he could not recall his own name or those of many common things. An examination of the injury had disclosed a small circumscribed compound depressed fracture of the sknll, located near the lower end of the fissure of Rolando. On the following day the depression was elevated and the aphasic symptoms had all disappeared. The case had impressed the fact that a circumscribed compression, due to traumatic influence, might limit its effects to one motor center only.

Dr. T. H. Manley, of New York Connty, said it was necessary to divide intracranial lesions into two classes—viz., those of an extrinsic and those of an intrinsic origin; those arising

from violence or mechanical influences, and those resulting from pathological changes within the skull. He confined his observations to lesions of a traumatic character, although what was said concerning the changes which lay in the way when those were treated by active surgical intervention would practically apply with slight modification to intracranial formations of a constitutional origin. Cephalic lesions attributable to trauma were commonly of a compound nature, being associated with contusion, laceration or puncture of the scalp with the underlying textures, with fracture or depression of the osseous plates of the skull, and hence we might with propriety designate them cranio-cephalic lesions. Conditions following cranial injuries in which the patients survived had reference to (1) shock, (2) laceration of brain substance, (3) hæmorrhage, (4) inflammation, (5) purulent formation, (6) localized ulceration, breaking down or softening. The utility or justifiability of operative interference depended on a multiplicity of circumstances, which demanded a most careful consideration. It was true that operations were frequently done on patients while in a state of shock and coma; it was also true that diagnosis could not be made at such a time. In a general way, it might be said that fractured or depressed bone of the skull could, when necessary, be expeditiously dealt with by the trephine. It was well known that we might have a laceration or injury to the brain without evident injury to the skull; and, on the other hand, the brain might be injured without symptoms occurring of sufficient gravity to make trephining admissible. The author did not believe in the reimplanting of bone in the skull, and did not think that osseous union took place, thereby leaving the brain susceptible of hernia cerebri. It was needless to say that the dura mater was always exposed to laceration when the large trephine was employed. Hæmorrhage was a symptom considered by many as one of the most dangerous to occur in trauma of the brain, but the author did not see why it should be so. He thought that in many cases, if it were let alone, absorption would take place, and at any rate the trephine in most cases increased the danger. Since the advent of antiseptics, combined with cleanliness, the danger of inflammation arising as a sequela of the trephine was eliminated, though not wholly banished. While with these means the trouble might be avoided, still mechanical irritation or constitutional predisposition often favored inflammatory processes. But meningitis was at times absolutely unavoidable after trephining. The author thought that in traumatic meningitis trephining for the purpose of draining and irrigating was not only useless but almost criminal. In the cases in which the operation had been done for this purpose there was no doubt that life had been shortened. He had never seen abscess follow the use of the trephine. When the use of the trepan was attended with or followed by much laceration of brain substance, or by the division or occlusion of the vascular supply, that part which was exposed thereby gradually disintegrated and was absorbed; insanity might result or recovery ensue. Anæsthetics increased the vascularity of the brain, so that it stood to reason that a brain after trauma should be kept as quiet as possible, and would not be benefited by this anæsthesia. Manipulation at such a time was also bad. The author thought that in many cases of trephining for trauma where death had occurred the anæsthetic had been an important element in the cause. For trephining to be stripped of elements of danger, it required an exact anatomical knowledge and a careful discriminating judgment.

Hypnotism.—Dr. Ernest Schmid, in his remarks upon this subject, said nobody hesitated to admit the influence of the body upon the brain. Eminent alienists maintained that no diseased state of the mind ever existed without a pathological condition of some portion of the brain. Why should we then hesitate to admit the influence of the mind upon the body? The author held that every unconscious imitation was a transfer of a brain movement communicated to another brain in such a manner that the brain which repeated this movement of the first brain adopted it as one of its own originating, and not a repetition. On this rested the great problem of hypnotism. That the view of the contagiousness of brain movements of physical, intellectual, and moral diseases was not a singular one, and was demonstrable among other things by the fact that not a few alienists had formed the belief that mental aberration might be communicated to a sound mind by example and daily intercourse with the insane. There did exist within us a secret force which constantly conformed our thoughts to our actions and our entire inner being to our external habits. The speaker was convinced that the true essence of hypnotism possessed kindred elements to those thoughts. It was the imparting of a brain movement to others or the creating a new one in another which became as the other self-originated thought. That the hypnotic state could be produced was an established fact. Like all other therapeutic measures, it had its circumscribed sphere, but its usefulness was destined to become very great.

Retention of Urine from Prostatic Obstruction in Elderly Men: its Nature, Diagnosis, and Management.—This was the title of a paper by Dr. J. W. S. Gouley, of New York County. (See page 477.)

Dr. J. A. Wyeth, of New York County, said that in cases of persistent cystitis it was his practice to perform suprapubic section; he thought this the best method for dealing with this very obstinate disease. This operation in his hands had given better results than when treated by the urethra. Not only was immediate relief obtained, but a better command of the bladder was possible. He had only been doing this operation the last two years, but in that time about thirty cases had been so treated, five of which were tumors of the prostate, good results being obtained in all. He thought that for prostatic tumors the high operation was by far the best. It was his method in removing such to use the clamp forceps, and, with the fingers at the prostate, gradually to twist them off, using the actual cautery to the stump. Relief had always been prompt, and in only one case did the bladder fail to resume its function. The speaker had found that the oil of gaultheria was the best remedy to prevent the decomposition of urine. He gave it by the mouth, four or five drops, three or four times daily. When this drug was given, the urine would not decompose. The Trendelenburg drainage-tube was the one used, and six to eight weeks was the longest it had ever been necessary to leave it *in situ*.

Dr. Gouley was in full accord with the speaker as to doing suprapubic cystotomy for the removal of prostatic tumors, but he would not do the operation for this alone, but rather incidentally. He believed that in the majority of cases the bladder could best be reached through the urethra, and as for doing the operation for the purpose of cleansing and drainage, it should not be thought of. In cases of contracted bladder from prostatic obstruction, it was the speaker's practice to use hydraulic pressure to dilate, frequently increasing the capacity of the bladder from half an ounce to four ounces. He did not think it necessary to give anything by the mouth for the purpose of preventing decomposition of urine, when we had the means of applying it directly in the bladder.

The Address on Surgery—The Ligature of Arteries.—Dr. Stephen Smith, of New York, said that his paper had been prepared with a view of noticing some of the contributions of American surgeons to the improvement and development in the ligature of arteries. The general surgical history of this work for the cure of aneurysm might be divided into three epochs.

The first came down to 1785, and was known as the old method; the second, or intermediate period, was known as the new method; while that of the third, or present period, was called the antiseptic period. The principle upon which the old method was based was the obliteration of the aneurysmal tumor by freely opening the sac and promoting suppuration. The feature of the operation which had excited most interest among surgeons, and which had led to improvements, was the method of arresting hæmorrhage. At first the open artery was plugged after the sac was incised, pledgets of cotton being sometimes employed. Subsequently the open artery was ligated at the bottom of the sac, and then the sac was closed and allowed to suppurate. Then the ligation was done outside, but close to, the tumor, with the subsequent incision of the sac. Again, ligatures were applied one above and the other below the tumor. Whatever the variation in detail, the operation had always terminated by the opening of the sac. The speaker then went on to trace the steady advance of operative work in this direction. Of the work of Hunter, he said that a review of the surgical literature of that period made it very evident that Hunter's operation was only one step, and not a very long one, in the treatment of aneurysm by operative methods. It had proved that the condition might be cured by the simple ligature of the artery on its proximal side, without incision of the sac and incurring the danger of subsequent suppuration. The suggestion of Brasdor—that the ligature should be applied on the distal side of the tumor—was important, as it had enabled the operator to successfully treat a class of cases in which it was impossible to ligate the main trunk on the cardiac side. Mott had heartily approved of the operation, and the success that had since attended it evidenced that surgeon's practical sagacity. After going very thoroughly over the whole ground in elaborate historical survey and paying graceful tribute to the work of Post, Mott, Rodgers, and others identified with progress in this direction, the author stated that the part borne by American surgeons in the history of the ligature of arteries was most favorable. They had not only been pioneers in enlarging the boundaries of this field of practice, but they had cultivated it with a degree of success unrivaled even by British surgeons. Statistics demonstrated that during the first three quarters of the present century, of sixteen operations upon the innominata, six were done in this country. Of these operations, an American surgeon had performed the first. Of thirteen ligations of the subclavian in the first part of its surgical course, Americans had performed five. An American surgeon had alone ligated the subclavian within the scaleni. It was, however, on the 31st of December, 1868, that an event had occurred which was destined to be the final consummation of all improvement in the ligature of arteries. This was the occasion of the application of ligatures to the carotid of a calf by Mr. Joseph Lister. The ligatures were of two different kinds, and were applied at intervals of about an inch and a half. The cardiac ligature was composed of three strips of peritonæum from the small intestine of an ox, firmly twisted; the distal end was made of fine catgut. Both had been treated with a saturated solution of carbolic acid. The ligatures were cut short, one end being left longer than the other. The wound was completely closed, and it had promptly healed. Thirty days after the operation the parts were examined post mortem. There was an entire absence of inflammatory thickening in the vicinity of the vessel. The knots of the distal ligature had disappeared, and the only indication of the end which had been left long was a black speck here and there upon a delicate cellular tissue in connection with the vessel. The cardiac ligature was continuous in structure with the arterial wall; the short end had disappeared, but the knot was represented by a soft, smooth lump, in the center of which and lying close to the artery was a small residual portion of the original knot, quite distinct from the living tissue around it. Between the proximal ligature and the heart the formation of a coagulum had been entirely prevented by a large vessel taking origin immediately above the part, which had thus borne the brunt of the cardiac impulse for a full month. Clots had been formed on the distal side of the ligature. A more minute examination showed that the material which had been formed at the expense of the ligature was a beautiful example of fibro-plastic structure. At the situation of the distal ligature the structure of the vessel had seemed to be entirely unaffected. The middle coat was neither thicker nor thinner than the neighboring parts. The vessel, so far from showing any signs of giving way, had appeared to have gained additional strength; the encircling ring of new tissue, incorporated with the arterial walls, must have had a corroborative effect. Mr. Lister, in commenting upon this result, had made the assertion that the application of a ligature of animal tissue antiseptically upon an artery, whether tightly or gently, virtually surrounded it with a ring of living tissue, and strengthened the vessel where it constricted it. A more complete revolution in practice could hardly be imagined. Mr. Lister's further assertion that the surgeon might now tie an arterial trunk in its continuity close to a deep branch, secure against secondary hæmorrhage and deep-seated suppuration, had been amply verified. A case in point in the author's experience was that of a man, aged forty, who had suffered from cancer of the tongue, tonsil, and pharynx, and had come under observation at a stage of the disease to avoid the repetition of the hæmorrhages which had already occurred, and of which the patient stood in great dread. The speaker had ligated with carbolized catgut between the divisions of the common carotid and the superior thyreoid branch of the external carotid. The ligature was drawn tightly, but not so firmly as to divide the coats of the vessel. The man dying soon after from inanition and exhaustion due to his disease, it was found post mortem that the operation had accomplished all that was expected of it. The common carotid was perfectly free and without change. At the bifurcation and along the extent of the internal carotid the caliber of the vessels was normal and there was no inflammatory product. At about a quarter of an inch from the origin of the external carotid the caliber of that vessel suddenly diminished, and an eighth of an inch higher it was completely closed. There was no evidence that clot had ever existed. Externally there was a bulbous enlargement at the seat of the ligature. The artery seemed to be encircled by a ring of newly formed tissue, as hard and dense as a cicatrix. The result of the ligature, as a whole, was (1) the closure of the artery immediately by pressure, (2) the closure of the artery permanently by the union of the opposing surfaces of the living membranes, and (3) the strengthening of the artery at the point of ligation tenfold by the formation of an immense ligature of fibrous tissue. Standing upon the present delectable heights, said the speaker, how vain seemed the struggle of the fathers in this branch of surgery! Operations which they had performed only after days and nights of wearisome study and anxiety might now be turned over to the hospital student for his technical improvement.

The Therapeutics of Exophthalmic Goitre.—Dr. E. D. Ferguson, of Rensselaer County, read a paper with this title. Exophthalmic goître, he said, was not a common disease, and yet it was not so rare as to render it a curiosity. Though the disease was one with sufficiently well defined characteristics to allow of its ready recognition, still errors of diagnosis might and doubtless did occur. The fact was that enlargement of the thyreoid body was not peculiar to the disease, and that a frequent pulse was attendant on a multitude of morbid conditions, and

occasional prominence of the eyes might be added from causes not the same as the condition determining the development of exophthalmic goître. The conclusion that the condition was not at any rate a pathological unit had been strengthened, in the judgment of the writer, by the results of the use of digitalis, for in every instance in which he had felt confident of the diagnosis that drug had not only failed to afford relief, but was apparently productive of injury. The writer then gave in detail the histories of several cases of exophthalmic goître treated with strophanthus. The administration of this had afforded prompt relief, the patients being able to return to their ordinary occupation. In no instance had either the exophthalmia or the goître been entirely removed, and so far as the latter was concerned, the author would not expect its removal, for when the enlargement had existed for some time it became of so dense or fibrous a consistence as to preclude the idea of its complete removal. There was, however, a notable degree of improvement both in the exophthalmia and in the thyreoid body, but it was impossible to express in mathematical terms the changes in these features of the disease so well as could be done in the rate of the pulse. Not only were the rate and rhythm of the contractions favorably influenced, but in these cases there undoubtedly existed a dilatation of the left ventricle which improved so as to leave no physical or symptomatic evidence of cardiac lesion. Recent pathological considerations tended to place exophthalmic goître in the category of the neuroses, and the locus of its origin in the floor of the fourth ventricle. Still, the evidence was not such as to give any clew concerning its ætiology or treatment, aside from clinical observations, and consequently there was no explanation to offer as to the method by which strophanthus afforded relief, aside from the idea that first suggested its use, and that was to relieve an apparently overtaxed heart through the lessening of the resistance in the systemic circulation which was alleged to be its action. Aside from any theoretical consideration as to the way in which the agent acted, the fact remained that benefit was apparently the direct result of the use of strophanthus—a benefit so notable as to almost justify the announcement of a cure in some of the cases. The only preparation used by the writer was the tincture, given by the mouth, three times daily at each meal, the initial dose being from eight to ten drops, which was increased, if necessary to reduce the frequency of the pulse, to fifteen or twenty, or even twenty five drops. Whether its apparent utility would bear the test of time and larger experience was still problematical. At present it seemed to be our most valuable therapeutic resource in exophthalmic goître.

Dr. Cronyn was glad that the speaker had given digitalis its proper place in the treatment of the disease.

Dr. A. L. Carroll, of New York County, said that he had been impressed with the difference which existed in the preparations of the drug strophanthus now in the market. He thought he had been the first to employ it here after the publication of the first paper on the subject. His case was one of dilatation following valvular lesion. Its action had been practically nil. He had then directed that another preparation should be procured. This had produced marked physiological action after a few doses.

Obstetrics.—This subject was made the basis of special and general discussion, the following questions being propounded:

(1) How may the present prophylactic measures in obstetrics be more extended and applied?

(2) Is the present technique in the management of labor and convalescence in accordance with sound physiology?

(3) To what extent have the surgical means of treatment of labor complications been successful, or should these complications and the process of repair have been more generally left to Nature?

(4) What influence would a more advanced obstetric science have on the biological and social condition of the race?

Dr. S. B. W. McLeod, of New York County, presented the first paper on this subject. He said that as a science obstetrics was conservative, but was pre-eminently progressive as an art. Antiseptics, meddlesome midwifery, and prophylaxis were then fully dealt with. The support of the perinæum was the subject of much consideration. The dorsal and the lateral postures of the patient in labor and the use of bandages had their advocates, and these not a few. It was worthy of special attention that, while there were about one hundred and thirty medicines now before the profession, those that were designated "new remedies," a few of these, perhaps eight, were of use in obstetrics. Ergot as an oxytocic still remained without a successful rival. The tears in ruptured uteri were sewed under antiseptic details, and these lesions always offered prospects of recovery.

Dr. W. McCollom, of Kings County, thought that between extremes there was always a golden mean. Savage and untutored natives did not become extinct by reason of puerperal fever, nor did all the civilized women die because of the amount of bichloride that was thrown into the gaping veins of the recently emptied uterus. In answer to the question propounded, he should say that all medical students should be instructed that if, when in practice, they were called to a case of obstetrics, they should first take a Russian bath, have the hair cut and shampooed, and buy a new suit of clothes. On entering the lying-in chamber, the physician should, if he had touched the door-knob, plunge his hands into a strong solution of carbolic acid or bichloride. Then he should have a steam atomizer at work casting a spray that would act like a Gatling gun on any bacilli that might have come in out of curiosity or with fiendish intent. The bacteria must then be dug from the finger-nails and thrown into the fire. Then, after again washing the hands and face in bichloride, the chemically pure accoucheur might make an examination when the patient told him that the child was coming. The patient should have a constant stream of bichloride thrown on the genitals, or have the nates immersed in a tub fitted to the bed, full of the same material. If the child, when born, should swallow some of the fluid, it would at once kill any bacilli of which it had inadvertently partaken *in utero*. No competent practitioner would allow the child to drown, of course. If the case should be one of breech presentation, a cork should be adjusted within the sphincter ani to prevent the meconial cocci from getting out too soon. The douching or hip-bath should be continued till the placenta was expelled. Then a bichloride pad should be placed over the genitals and they should be hermetically sealed, not to be opened except under like antiseptic precautions. They might think him frivolous, but he had heard as ridiculous teaching from high authority. As a matter of serious fact, he would have everything as clean as possible. The speaker made this the *sine qua non* of all procedures throughout the whole parturient period, whether complicated or not.

Dr. G. T. Harrison, of New York County, said that the most important work of the obstetrician was to see that he did not infect his patient. Vaginal examination should be made only in the interest of the mother and child. The most extreme limitations, and even entire omission of internal examination, might be very well compensated for and replaced by external methods. Of the paramount importance of the thorough disinfection of the hands, and of all instruments, vessels, and clothing likely to be brought into contact with the parturient woman, so-called subjective antisepsis, we were all agreed. Of the necessity for an objective antisepsis, so far as thorough

cleansing and disinfection were concerned, there could be no question. A streptococci invasion through so-called self-infection by the natural genital secretions was impossible, and the healthy parturient woman might be regarded as aseptic. Virulent infective germs always came from without. Antiseptic vaginal douches should not be given, therefore, before or during the birth in a normal condition of the pregnant or parturient woman. These were also contra-indicated under the same conditions immediately after the birth and during the puerperal state, as they were not only useless but positively injurious. It must be borne in mind that the course of birth was mechanically retarded by the loss of the vaginal mucus, as one of its physiological functions was to diminish friction and facilitate the passage of the child's head through the canal invested by it. The detachment and expulsion of the placenta from the uterine body into the lower uterine segment occurred spontaneously, and, according to physiological law, required for its completion from five to fifteen minutes. The author would not interfere with the placenta unless there was some obstacle in the way of its complete expulsion, and would not adopt external manipulation. The natural forces were fully adequate to the detachment of the placenta, and there was no necessity of any kind of active interference on the part of the obstetrician to assist the physiological act. In regard to hæmorrhage, Credé's method and Schroeder's modification were not objectionable when properly employed with reference to retained portions of decidua and chorion. Too much emphasis could not be laid upon the importance of an ocular inspection of the external genitalia immediately after the expulsion of the placenta in order to ascertain the existence of any wounds about the vaginal outlet. During the puerperal state two predisposing factors came into play which rendered it comparatively easy for dislocating forces to unfold their efficacy. All the pelvic organs were in a condition of relaxation and the uterus was enlarged and swollen; if, therefore, the patient lay persistently on her back and the bladder was allowed to become distended, and if the rectum, in addition, was left permanently filled, it must follow as a neces sary consequence that the fundus uteri was forced backward on the one hand and the cervix was anteposed on the other hand, involution was hindered, and retro-utero-flexio was the result.

Dr. T. J. McGillicuddy, of New York County, thought that the skillful use of the forceps undoubtedly decreased infantile mortality, but its bungling manipulation increased it. It was said that the forceps was applied much more frequently in private than in hospital practice. This was to be deplored, because in many cases the child often lived only a week or two, and generally died from some cerebro-spinal lesion. Episeotomy was an operation which seldom did what was expected of it.

Dr. W. H. Robb, of Montgomery County, thought that we might look forward to the time not far distant when the advance in obstetrical science would furnish the instruments and therapeutic resources by which the most deformed women could be safely delivered of a living child. Obstacles to the safe delivery of the mother resulting from deformity of the child would be surmounted in a similar way. All injuries to the mother resulting from labor would be immediately repaired and any injury to the child would be promptly treated. With these accidents successfully met or prevented we should find at our command resources for the prevention of puerperal diseases. New remedies would be discovered, new methods would be tried until a more advanced obstetrical science furnished means by which the diseases and accidents incident to gestation would be relieved, the changes resulting from difficult labor overcome, and complications of the puerperal state entirely prevented. The race would be benefited by the preservation of many valuable lives. A goodly number of mature and healthy women would be saved. Women who now suffered for years as the result of injury or disease due more or less to the complications of the lying-in state, women who from protracted suffering were rendered almost demoniacal, would be preserved to adorn their natural sphere as ministering angels.

Dr. A. P. Dudley, speaking to the point as to whether the complications and processes of repair should be more generally left to Nature, spoke very emphatically upon the subject of the Cæsarean section. It was a measure, he contended, now very nearly perfect in technical detail. If properly done, he believed it would in time become more successful than craniotomy done when a woman was thoroughly exhausted by her own efforts to expel the child naturally or by the efforts of the physician to do so with the forceps. One of the chief conditions of success in this operation was that it should be begun early, before the patient became too exhausted. He had never given a vaginal douche before the birth of the child, and had never had a case of sepsis. He would suggest that the existence of a condition of pyosalpinx was likely to prove a very fertile source of infection at the time of delivery. In such event the uterus might have been washed out and every antiseptic precaution have been taken; there might exist no injury to the cervix or perinæum, and still puerperal fever would develop and the patient die. The same result might ensue from any diseased condition about the bladder. He thought he had seen such cases in hospital practice. As a matter of fact, it was seldom that sepsis occurred, except as the result of gross neglect. It was his rule never to consider a case of labor ended till he had examined the uterus. It was very easy to pass a speculum. He was in the habit of delivering the woman on her side. In this posture he had the perinæum well in view and under control. He could sew up a tear and the patient never know it. A few drops of cocaine were all that was necessary. He then introduced a needle at the top of the rent and repaired the injury with an over-and-over catgut suture. His answer to the second question propounded would be "No."

Dr. C. C. Frederick, of Erie County, said he thought that the point of primary importance to the race to come was the question of the present preservation of the health of the species. Reviewing the accidents during labor, he said the predisposing causes of injuries of the ureters at that time were found in a low position of the bladder and ureters, and an impaired nutrition of these organs during gestation, due to œdema and pressure. When the membranes ruptured before dilatation was completed, the cervix and the bladder were carried down into the pelvis before the advancing head, thus exposing the ureters to danger of injury. The use of forceps in such cases was a frequent cause of injury. To prevent injury of this kind, complete dilatation should be secured, if possible, before the membranes ruptured. If they did rupture early and the cervix was tense, support should be given to the bladder and anterior vaginal wall, and retraction of the cervix over the vertex secured as early as possible. The discussion between the advocates of the expectant method of placental delivery and the followers of Credé still continued, especially in Europe.

Dr. A. L. Carroll read an elaborately prepared statistical paper bearing upon the subject of the discussion. (To be published.)

The Medicine of the Classics.—The Hon. C. H. Truax, of New York, delivered an address on this subject. He took for his remarks the humorous side of the picture and brought out, as the result of a great deal of very scholarly research, the fact that even as far back as Æsculapius the physicians of that period were given to playing upon the credulity of their pa-

tients and were as unscrupulous in the matter of fees when opportunity offered as their possibly equally necessitous brethren of to-day.

The Physician as a Witness.—Dr. Martin Cavana, of Madison County, in a telling paper on this subject, urged upon the profession to take more pains to qualify for the work of expert testimony before going into the witness box. Then it was well to adhere to the one or two authorities which had been studied and to disclaim any familiarity with others. While the main anatomical features likely to come up should be looked up, the witness need never hesitate to admit having forgotten such portions of the matter as he could not readily recall. He could then take the opportunity to remind the court that even the lawyers were obliged to consult their authorities. It was well to secure the favor of the entire court by manifesting a spirit of fairness to both parties in the action. Technicalities should be avoided and the purport of every question by the cross-examination well weighed before answering. People with no business in the antopsy room should be kept out of it. If the fire-shovel or wood-saw was used in making the dissection, it was well not to let any non-professional eyes witness the fact, lest it should lay the operator open to unpleasant remarks.

Some Observations on Bone and Skin Grafting was the subject of a paper by Dr. B. M. Ricketts, of Cincinnati, Ohio. Grafting or dermapenthesis in the vegetable kingdom had been developed to such an extent that there was hardly any limit as to what could be done in the way of repair and production, beauty and financial gain being the greatest desiderata. While the results of grafting animal tissue were less gratifying than those of vegetable tissue, much had been done to convince us that the limit was far beyond anything yet attained. Of the many questions that arose relative to the subject of bone and skin grafting, there were three most prominent, namely: 1. Where and how should skin be grafted upon raw surfaces caused by injury, or by the removal of malignant or non malignant growths? 2. How and where might bones be restored? 3. Should fragments of normal bone be permanently removed except in case of amputation? The author limited the first question to the cases where the edges of the resulting wound could not be immediately coapted, coaptation being given preference under all circumstances. In the second class of cases he included the restoration of the bones of the hands, feet, arms, or legs that had been removed by trauma or surgical interference without amputation. Bone grafting or osteopenthesis, while not so far advanced, was capable of the same successes as skin grafting. Enough had already been done to show that its confines were not narrow by any means. As to the third question—that of bone fragments in either compound or compound comminuted fractures—where a bone was crushed or broken into two or more pieces, the greatest care should be taken to replace the fragments and to offer every opportunity for their union, that the strength and original shape of the bone might be preserved. That this might be more certain, all clots and foreign matter should be cleared away and shreds of tissue removed from between the fragments, which should be immediately restored to their proper places. In some cases, as in the long bones, the fragments might be firmly brought together with silver wire, which could afterward be removed. The author looked upon exploratory incisions in cases where the conditions of the bone could not be determined as justifiable and as being the only means of knowing the exact condition, clean surgery being the safeguard. A number of specimens of bone wiring in the dog were then exhibited.

Abdomino-pelvic Serous Cysts and Cystic Formations.—This was the subject of a paper by Dr. T. H. Manley, read by title. The author described a serous cyst as a structure of a low grade of development not under ordinary circumstances producing mixed elements, and, when unencumbered by pathological changes, maintaining its original histological character. The anatomical essentials were an investing envelope, composed of cellular elements, with more or less numerous nucleated strands of fibrous tissue, and becoming eliminated only by age or inflammatory changes. Internally the lining was of endothelial cells, having the power of both increasing and diminishing the quantity of the encapsulated liquid. The liquid contents, although designated serous, possessed no property in common with the serum of the blood except in physical character. These cysts, he was convinced, had for their origin an undiscovered microbe, which gained entry by way of the aerial or alimentary passages, and, when finding suitable soil or the system in a receptive state, they rapidly developed. In considering the ætiology of these formations, the writer pointed out that age and sex were important factors, females being the greatest sufferers. The formations might be regarded as evidences of a degenerative process, and, inasmuch as serous cysts were seldom seen except in the reproductive and urinary organs, they might be regarded as in some manner, as yet inexplicable, connected with the functional derangements in this region. After an exhaustive review of the morbid anatomy and symptoms, the writer, in dealing with the subject of treatment, said it would not do to be deluded by the reports from palatial hospitals, as such statistics could hardly be regarded as reliable criteria for the isolated rural practitioner. Not that such statements were wanting in truth or were varnished, but because there was but little comparison in the facilities for operating. In many hospitals the cases were selected with great care. The advice given by the elder generation of surgeons and practitioners was sound. They recommended marriage as a physiological relief when the cysts were of recent growth in the pelvis of the female. It was argued that, when fecundation followed copulation, the immediate active vascularity in the formerly languid, congested capillaries soon aroused the latent vitality in the reproductive organs, and that superfluous adventitious productions, recent in growth and moderate in size, underwent degenerative changes and disappeared. He had never seen any benefit from massage or electricity. When cystic disease threatened to compromise health and became the source of pain or discomfort, internal remedies would make no impression, and active interference was in many cases all that was left. Stupendous progress had been made, it was true, but it must be remembered that all operations involving the abdomen were fraught with more or less danger, and all entailed mutilation; hence conservatism should be the word.

Functional Disorders of the Nervous System of Women.—This was the title of a paper by Dr. F. J. McGillicuddy. Under this heading he classified a number of diseases which, although not entirely restricted to women, were found much more frequently in the female than in the male sex. The hysteroneuroses were gastric, glandular, cardiac, brachial, pharyngeal, spinal, cerebral, ophthalmic, and dermatic—hystero-epilepsy, hysterocatalepsy, trance, lethargy, narcolepsy, ecstasy, hysteric hypnotism, somnambulism, migraine, and recurrent orgasm. A knowledge of the different hysteroneuroses was extremely important, otherwise the wrong organs would get the medication. In the menstrual hysteroneuroses there was undoubtedly local congestion dependent on reflex irritation. The globulus hystericus was most assuredly in many instances a local congestion, which could be determined by placing the finger, during its existence, on the front of the throat, when it would be found to be very tender to the slightest pressure. Hystero-epilepsy was only hysteria in the highest degree, and not hysteria complicated with other neuroses.

The Management of the Placenta in Abortion.—Dr. Darwin Colvin, of Wayne County, in a paper on the correct method of dealing with the placenta in the second stage in cases of abortion, said he made it a rule never to leave the parturient chamber until the placenta was in his hands. He should consider that in the event of any trouble arising out of neglect to do this a physician would be guilty of malpractice.

Dr. McLeod said that in a very extensive obstetric practice he had never had a death occur from sepsis due to retained secundines.

Dr. Ferguson said that if that was really the case, the last speaker was very much more lucky than most of his hearers.

The meeting closed with the introduction of the newly elected president, Dr. Stephen Smith, of New York.

NEW YORK ACADEMY OF MEDICINE.

Meeting of October 16, 1890.

The President, Dr. Alfred L. Loomis, in the Chair.

Hydrophobia; its Clinical Aspect.—Dr. L. C. Gray read a paper with this title. At the very threshold of the subject, he said, we were confronted by the question as to whether there was such a thing as rabies or hydrophobia. There had been much and bitter discussion upon this point during the last few years. Those who would answer this question in the affirmative alleged as proof the fixed belief of ages, and the many epizootics of which we had historical record. The disease had never been very prevalent in this country, although local epizootics of it had been reported from time to time. It would also appear to be conclusively proved that many people had died after being bitten by rabid animals. But there had sprung up in America in the last few years a small number of very decided opponents of these statements. The extreme variability in the period of incubation in hydrophobia lent credence to the belief, that was firmly held by many competent observers, that death could occur from fear, with symptoms closely resembling those of the true disease. Although a recent writer had characterized such a belief as childish, it was nevertheless a matter of clinical observation that great psychical shock could produce mental disease and death. The author related several cases which had come under his own notice that bore out this statement. In the city of New York during a period of thirty-five years, from 1855 up to the present time, there had been but seventy-six deaths from hydrophobia. The author believed, from a review of the subject, that he was justified in the following conclusions: That frequent mistakes were made in the diagnosis of rabies and hydrophobia; that the so-called dumb rabies was a symptom of simple purulent meningitis and meningo encephalitis; and that very few cases of either rabies or hydrophobia had been observed in New York city or in the country at large. Admitting all this, however, the question still remained as to whether there was a true rabies or a true hydrophobia. The author believed that there was a disease running a fatal epizootic course in the dog and also other lower animals, and capable of being communicated to the human being and causing death, although the evidence of this would rest mainly upon the pathological and experimental considerations which would be presented by Dr. Dana and Dr. Biggs.

The Reality of Rabies was the title of a paper by Dr. C. L. Dana. He said that in order to prove that a certain disease was autonomous, distinct, and special, we must establish the fact that its ætiology and its clinical history were essentially uniform, or that the anatomical changes found after death were the same, or that inoculations of animals with the secretions or tissues of the victim of the disease reproduced the disease. The proof of the unity of a disease was, therefore, (1) ætiological, (2) clinical, (3) anatomical, and (4) experimental. The unity of some diseases could be established by only one or two of the four methods, not by all. In the case of rabies, a comparatively rare and obscure disorder occurring in the lower animals, so that only objective symptoms could be studied, it was important that all the proofs should be brought into use. The ætiological and clinical proof of the existence of the disease rabies was based upon the fact that different observers in every part of the world, from time immemorial until the present time, had all united in describing a disease in the dog having essentially the same origin, clinical symptoms, course, and termination. It was an established fact that the clinical symptoms of rabies were not absolutely sufficient for a diagnosis. Of the anatomical proof there was no constant change to be found in this disease. The nervous centers, which were the parts chiefly involved, were congested and occasionally showed hæmorrhagic and softened spots, and later in the disease, if it was prolonged, evidences of increased vascular activity occurred—exudation of leucocytes into the circumvascular spaces—and one might find the beginnings of a multiple focal myelo-encephalitis or of focal necrosis. The symptoms of rabies it was evident were caused not by any organic change in the nervous tissues, but by a profoundly distinct poison, the product undoubtedly of microbic activity. This poison acted first upon the nerve cells and fibers, and only later did it affect the vascular apparatus. It had been by a continuation of ætiological, semeiological, and anatomical evidence that in the past the autonomy of rabies had been established. In recent years, chiefly through the labors of Pasteur, the experimental proof had been added, and this, in the opinion of most, if properly carried out, was an absolutely positive one. Pasteur found that the virulence of the rabietic poison was confined chiefly and most uniformly to the brain and spinal cord. He found that rabbits inoculated subdurally with this virulent nervous tissue, after a certain incubation developed a paralytic disease having a uniform course and termination, with no marked anatomical change discoverable after death. He found that this disease was true rabies, because when dogs were inoculated with the rabbit's virus they were attacked, after a period of incubation, with the symptoms of canine rabies. In the light of such scientific work as Pasteur had done, the author did not see how one could deny that the specific character of rabies was experimentally proved. But, beyond this fact, other experimenters had abundantly confirmed Pasteur's results. Was hydrophobia a specific inoculable disease identical with rabies in the lower animals? The author had spent a good deal of time upon this point, because its establishment was the key to the whole question of the reality of rabies in man, and to all the practical points regarding its prevention. The proof that a specific inoculable disease known as rabies or hydrophobia affected man was furnished by the four criteria previously mentioned, viz.: (1) the ætiological, (2) the clinical, (3) the anatomical, and (4) the experimental. In the attempt to discredit Pasteur or disprove the existence of human rabies, a great deal had been made of pseudo-hydrophobia or lyssophobia, and of its alarming frequency and extraordinary dangers. As a matter of fact, there were no authentic clinical records of a single case in which fear of hydrophobia had caused a disease measurably similar to rabies. And there was no genuine case of death from this particularly hypothetical phantasm. There had been perhaps fatal cases of tetanus following the bites of dogs, and there had possibly been fatal cases of acute mania, generated in those predisposed by fright. These extremely doubtful instances would explain the fatal cases of so called pseudo-hydrophobia. Closely connected with the subject of the specific character of

rabies in man and the lower animals came the question of the production of immunity from its horrible and fatal effects. The establishment of the specific inoculable character of a disease gave presumption in favor of the power of securing immunity from it, for to the great majority of specific diseases the animal body either naturally possessed or might acquire immunity. This was true of all, or nearly all, infectious diseases from syphilis to small-pox. The question now finally came, Could the immunity to rabies, which it was known could be conferred upon dogs, be conferred upon man. This could only be settled by statistics. From 1886 to 1889 Pasteur had treated 1,336 persons who had been bitten by animals proved to have been rabid, either by experimental tests or by the fact that other animals bitten at the same time had suffered with the disease. Of these 1,336, only 13 had died. Collected proofs of the proportion of deaths among persons bitten by rabid dogs, giving a reasonable and low estimate of the average, showed it to be fifteen per cent. There was, in the author's opinion, no experimental method, no pathological fact, and no prophylactic measure more firmly established than that antirabietic inoculations could be successfully applied to man. In demonstrating this, Pasteur had done more than simply save a few from a horrible death. He had established the principle of the possibility of protective inoculations in other specific infectious diseases. He had opened up an immense field for future productive labor—the prevention or regulation of scarlet fever, typhoid, typhus, and even phthisis was made to appear possible, and a revolution in medical practice of extraordinary importance could be foreseen.

The most important fact in the recent history of rabies was that all of Pasteur's statements concerning the procedure of rabies vaccination and its efficacy in experiments on animals had been in all essential particulars unreservedly corroborated by nearly all authors of the last two years. That there was yet much to learn about rabies was pretty clearly shown by the vast difference in the methods that were used with approximately the same results. In Pasteur's simple method, three or four c. c. of active virus, the strongest five days old, was used in the entire treatment. In virulence, probably the whole amount employed was not equivalent to more than one c. c. of the fresh medulla, and was used only after tolerance had been established by the use of a series of spinal cords possessing a gradually increasing virulence, commencing with one having no appreciable activity. In the intensive method the virus employed exceeded this by ten times in both virulence and amount. In Ferran's method, without any preliminary inoculations with weak virus, the fresh, most virulent virus was immediately used, not one c. c., but four c. c. daily, and this inoculation repeated on five successive days. According to Ferran, the more the virulence and the greater the quantity of virus introduced, the greater the immunity, and this immunity was immediately acquired apparently, for he commenced with inoculations of virus far exceeding in virulence and amount that which could have been introduced by any possibility through the bite of a rabid dog. On the other hand, another experimenter produced immunity by the frequent injection of almost infinitesimal quantities of virus. From the purely experimental side of the question, it seemed to the author that the evidence was very strong of the protective influence of Pasteur's inoculations in both animals and man. In fact, it appeared that an unprejudiced observer must either assume that there was no such disease as rabies, that Pasteur and others were not dealing with rabies, or candidly admit that the inoculations did give relative immunity. As to Pasteur's statistics and the relative mortality after the inoculations, the author confessed to the greatest incredulity. First, because he could find no evidence to justify the assumption that there were anything like as many cases of rabies in France or anywhere else as one would be led to believe was the case from the number of patients inoculated in Paris and in other antirabietic institutions. Second, it seemed to him, from personal experience in sending patients to the Pasteur institute, that little care was used to determine whether the persons had been bitten by rabid dogs, and no attempt was made to follow the history of the cases afterward. Pasteur's first assumption was that the virus of rabies was present in a concentrated form in the central nervous system, and especially the medulla oblongata and the spinal cord. This observation had been confirmed by several investigators, the author included. The second was that rabies might be produced with the greatest certainty by the subdural inoculation of other animals with portions of the brain and spinal cord of animals dead of rabies. Again, that the virulence of the virus could be increased and the period of incubation shortened by the successive subdural inoculations of rabbits. The fourth contention was that the rabietic virus present in the brain and spinal cord might be attenuated in a constant and progressive degree by drying the cord at a fixed temperature, and that the virulence was entirely destroyed after about fourteen days. Up to this point there could be no question about the complete acceptation of the conclusions of Pasteur. The author was unable to understand why the question of the apparent increase in the number of cases of hydrophobia had been so generally left out of consideration in the various reviews as to the value of the results obtained in the inoculation of human beings. In 1883 it was reported that 183 animals suffered from rabies in France; in 1888 this number had increased to 863. Statistics, to be sure, were not worth much; but when the records of all countries, as well as the consensus of medical opinion everywhere, showed that rabies had been an exceedingly rare disease, it was curious to know how one could accept without questioning the statement that three hundred or four hundred lives were saved annually in France, as many more in Russia, and a proportionate number in other countries where there were antirabietic institutes. In conclusion, it might be said that, experimentally in animals, Pasteur's method conferred relative immunity to rabies, and probably might also do so in the human being, but that the statistics of results derived from inoculation of human beings must be accepted with reserve.

Dr. H. C. Ernst, of Boston, who has done considerable experimental work in this field of inquiry, said that he regarded the results accomplished by Pasteur as among the greatest achievements of modern medicine. The speaker had been entirely converted to a thorough acceptance of the theory after conducting a series of inoculation experiments. If there was one thing certain in medicine, it was the unerring precision in the results obtained by the inoculation with these cord emulsions under the dura mater of the healthy rabbit. There was nothing like it in the whole range of scientific experimentation. As to the existence of a constant lesion pathognomonic of rabies, he did not know that this could at present be defined with scientific accuracy, but careful observation had demonstrated the very uniform presence of infiltration of the minute vessel walls in the medulla oblongata with white cells, engorgement of the veins, and occasionally circumvascular hæmorrhages. What appeared like small miliary abscesses were also present. The condition had been aptly covered by the term miliary bulbar inflammation. The speaker then gave the clinical histories of three cases of true rabies in man which had come under his own personal observation, and which, taken with the fact that a large number of dogs were affected at or about the same period, pointed to the recent existence of an epidemic of rabies in Boston. One of the cases cited in detail was of special interest, because the patient between the paroxysms was able to describe his condition. He had been specially

questioned as to whether there existed any repugnance to water, and had positively stated that there was not, but that any mental process connected with the act of deglutition caused an uncontrollable spasm of the muscles of the throat. This patient had also described himself as perfectly conscious of his acts during the violent paroxysms, but as being utterly unable to control himself. Even while he was thus quietly describing his sensations the fit would come on, and the next moment he would be on the floor struggling with four or five men. Then, as to the value of the preventive method, the speaker instanced the case of a boy who was bitten in August by a dog which within fifteen minutes had also bitten several dogs. Of these, two had died of rabies, and the father of the boy, becoming alarmed, had consulted the speaker. Inoculation was advised and submitted to twice a day. No bad symptom had resulted. Before the boy's return home a third dog had succumbed to unquestionable rabies. Whether there was anything in Pasteur's contentions or not, one thing was certain: he had got hold of a specific virus which could be transferred from one animal to another indefinitely, always producing a sequence of practically identical symptoms. The experiments made by Dr. Spitzka had not been carried far enough. They had produced something similar to the appearance of rabies in the rabbits, but had offered no sort of ground for comparison with Pasteur's experiments. While hardly wishing to stand up as a champion of the Pasteur method, if the statistics of the institute were not reliable, he was still bound to believe in the honesty in purpose of Pasteur and his assistants. It was a significant fact that, after the careful elimination of all cases in which an element of uncertainty existed, the mortality rate for those treated by inoculation under the method was only ninety-eight one-hundredths of one per cent. He expressed surprise at the statement that there could be no such condition as pseudo-hydrophobia or lyssophobia.

Dr. R. W. Birdsall said he had seen a number of cases of pseudo-rabies resulting from fright after a bite or scratch of a dog. These cases had not resulted in death, though he was not prepared to go so far as to say that death from fright was not possible. The nervous shock sustained might set up a series of changes, such as motor paresis, œdema of the brain, and coma, resulting in death. He did not believe we were yet in a position to be able to refer the phenomena of true rabies to the existence of one kind of specific germ. The effects might be due to the presence of distinct varieties.

Dr. H. P. Loomis had only considered the subject from a pathological standpoint. The findings tallied very much with those described by Dr. Ernst. Sections of the lower portion of the medulla oblongata had shown congestion of the capillary vessels and giant-cell infiltration of the adventitia, but no capillary hæmorrhages or thrombi.

Dr. Byron, who had made extensive experiments at both the Carnegie and the Loomis laboratories, had arrived at the conclusions that (1) inoculations of the specific virus of rabies under the skin were completely useless; (2) the results desired could never be produced by any process except subdural inoculation, and even then the effect was not inevitable. The question was a serious one, and the subject still open to further experimental research before any definite scientific conclusions could be formulated.

Dr. E. C. Spitzka said he had made no experiments on rabbits as intimated by Dr. Ernst, who had evidently not followed the points of the speaker's work. In the experiments made by him on dogs he had made no statement that these animals had represented true cases of hydrophobia, but, by the introduction of various irritating substances into the brains of these dogs, he had produced conditions of bogus hydrophobia. He was now associated with the conduct of a series of elaborate experiments on rabies the results of which could not as yet be formulated.

Dr. Gray thought the discussion had proved (1) that there existed undoubtedly in the lower animals a disease known as rabies, possibly made up of several diseases, due to different micro-organisms; (2) that this disease was more frequent in the lower animals than a similar disease in man known as hydrophobia; (3) that, while this so-called rabies in animals occurred very often in this country, it occurred less frequently in the human being; (4) that very few medical men had seen genuine cases of hydrophobia; (5) that cases of pseudo-hydrophobia were by no means uncommon, and that death could result from the condition; and (6) that there still existed considerable diversity of opinion as to the value of Pasteur's method, which would furnish material for discussion and incite to further experiment.

Miscellany.

Peroxide of Hydrogen and Ozone.—The following paper, published in the *Medical News* for October 25th, was read by Dr. Paul Gibier before the International Medical Congress at Berlin:

Since the discovery of peroxide of hydrogen by Thenard, in 1818, the therapeutical applications of this oxygenated compound seem to have been neglected both by the medical and the surgical professions; and it is only in the last twenty years that a few bacteriologists have demonstrated the germicidal potency of this chemical.

Among the most elaborate reports on the use of this compound may be mentioned those of Paul Bert and Regnard, Baldy, Péan, and Larrivé.

Dr. Miguel places peroxide of hydrogen at the head of a long list of antiseptics, and close to the silver salts.

Dr. Bouchet has demonstrated the antiseptic action of peroxide of hydrogen when applied to diphtheritic exudations.

Professor Nocart, of Alfort, attenuates the virulence of the symptomatic microbe of carbuncle before he destroys it by using the same antiseptic.

Dr. E. R. Squibb,* of Brooklyn, has also reported the satisfactory results which he obtained with peroxide of hydrogen in the treatment of infectious diseases.

Although the above-mentioned scientists have demonstrated by their experiments that peroxide of hydrogen is one of the most powerful destroyers of pathogenic microbes, its use in therapeutics has not been as extensive as it deserves to be.

In my opinion, the reason for its not being in universal use is the difficulty of procuring it free from hurtful impurities. Another objection is the unstableness of the compound, which gives off nascent oxygen when brought in contact with organic substances.†

Besides the foregoing objections, surgical instruments decompose the peroxide; hence, if an operation is to be performed, the surgeon uses some other antiseptic during the procedure, and is apt to continue the application of the same antiseptic in the subsequent dressings.

Nevertheless, the satisfactory results which I have obtained at the Pasteur Institute of New York with peroxide of hydrogen in the treatment of wounds resulting from deep bites and those which I have observed at the French clinic of New York in the treatment of phagedenic chancres, varicose ulcers, parasitic diseases of the skin, and also in the treatment of other affections caused by germs, justify me in adding my statement as to the value of the drug.

But it is not from a clinical standpoint that I now direct attention to the antiseptic value of peroxide of hydrogen. What I now wish is

* Gaillard's *Medical Journal*, March, 1889.

† The peroxide of hydrogen that I use is manufactured by Mr. Charles Marchand, of New York. This preparation is remarkable for its uniformity in strength, purity, and stability.

merely to give a full report of the experiments which I have made on the effects of peroxide of hydrogen upon cultures of the following species of pathogenic microbes: *Bacillus anthracis*, *Bacillus pyocyaneus*; the bacilli of typhoid fever, of Asiatic cholera, and of yellow fever, *Streptococcus pyogenes*, *Microbacillus prodigiosus*, *Bacillus megatherium*, and the bacillus of osteomyelitis.

The peroxide of hydrogen which I used was a 3·2-per-cent. solution, yielding fifteen times its volume of oxygen; but this strength was reduced to about 1·5 per cent., corresponding to about eight volumes of oxygen, by adding the fresh culture containing the microbe upon which I was experimenting. I have also experimented upon old cultures loaded with a large number of the spores of the *Bacillus anthracis*. In all cases my experiments were made with a few cubic centimetres of culture in sterilized test-tubes, in order to obtain accurate results.

The destructive action of peroxide of hydrogen, even diluted in the above proportions, is almost instantaneous. After a contact of a few minutes, I have tried to cultivate the microbes which were submitted to the peroxide, but unsuccessfully, owing to the fact that the germs had been completely destroyed.

My next experiments were made on the hydrophobic virus in the following manner:

I mixed with sterilized water a small quantity of the medulla taken from a rabbit that had died of hydrophobia, and to this mixture added a small quantity of peroxide of hydrogen. Abundant effervescence took place, and, as soon as it ceased, having previously trephined a rabbit, I injected a large dose of the mixture under the dura mater. Slight effervescence immediately took place and lasted a few moments, but the animal was not more disturbed than when an injection of the ordinary virus is given. This rabbit is still alive, two months after the inoculation.

A second rabbit was inoculated with the same hydrophobic virus which had not been submitted to the action of the peroxide, and this animal died at the expiration of the eleventh day with the symptoms of hydrophobia.

I am now experimenting in the same manner upon the *Bacillus tuberculosis*, and, if I am not disappointed in my expectation, I will be able to impart to the profession some interesting results.

It is worthy of notice that water charged, under pressure, with fifteen times its volume of pure oxygen has not the antiseptic properties of peroxide of hydrogen. This is due to the fact that when the peroxide is decomposed nascent oxygen separates in that most active and potent of its conditions next to the condition, or allotropic form, known as ozone. Therefore it is not illogical to conclude that ozone is the active element of peroxide of hydrogen.

Although peroxide of hydrogen decomposes rapidly in the presence of organic substances, I have observed that its decomposition is checked to some extent by the addition of a sufficient quantity of glycerin; such a mixture, however, can not be kept for a long time, owing to the slow but constant formation of secondary products having irritating properties.

Before concluding, I wish to call attention to a new oxygenated compound, or rather ozonized compound, which has been recently discovered and called "glycozone" by Mr. Marchand.

This glycozone results from the reaction which takes place when glycerin is exposed to the action of ozone under pressure—one volume of glycerin with fifteen volumes of ozone produces glycozone.

By submitting the *Bacillus anthracis*, *pyocyaneus*, *prodigiosus*, and *megatherium* to the action of glycozone, they were almost immediately destroyed.

I have observed that the action of glycozone upon the typhoid-fever bacillus, and some other germs, is much slower than the influence of peroxide of hydrogen.

In the dressing of wounds, ulcers, etc., the antiseptic influence of glycozone is rather slow if compared with that of peroxide of hydrogen, with which it may, however, be mixed at the time of using.

It has been demonstrated in Pasteur's laboratory that glycerin has no appreciable antiseptic influence upon the virus of hydrophobia; therefore I mixed the virus of hydrophobia with glycerin, and at the expiration of several weeks all the animals which I inoculated with this mixture died with the symptoms of hydrophobia.

On the contrary, when glycerin has been combined with ozone to form glycozone, the compound destroys the hydrophobic virus almost instantaneously.

Two months ago a rabbit was inoculated with the hydrophobic virus which had been submitted to the action of this new compound, and the animal is still alive.

I believe that the practitioner will meet with very satisfactory results with the use of peroxide of hydrogen, for the following reasons:

1. This chemical seems to have no injurious effect upon animal cells.

2. It has a very energetic destructive action upon vegetable cells—microbes.

3. It has no toxic properties; five cubic centimetres injected beneath the skin of a guinea-pig do not produce any serious result, and it is also harmless when given by the mouth.

As an immediate conclusion resulting from my experiments, my opinion is, that peroxide of hydrogen should be used in the treatment of diseases caused by germs, if the microbian element is directly accessible; and that it is particularly useful in the treatment of infectious diseases of the throat and mouth.

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Lectures and Addresses.

AN ADDRESS INTRODUCTORY TO THE REPORTS ON THE PROCEEDINGS OF SECTIONS IN THE TENTH INTERNATIONAL MEDICAL CONGRESS,

DELIVERED BEFORE THE NEW YORK ACADEMY OF MEDICINE *November 6, 1890.*

BY A. JACOBI, M.D.

MR. PRESIDENT: On August 4, 1890, during the first and largest general meeting of the Tenth International Medical Congress, there were three universal and spontaneous outbursts of applause. The first and most sympathetic greeted the name of James Paget, and never was there an ovation more deserved. The second rang through the immense building when it was announced that the government of the French Republic had sent thirty-four official delegates, and that nearly one hundred and fifty more Frenchmen had joined the congress. They had overcome political enmity and jealousy, disregarded a rather slighting reference to their "national insanity" of twenty years ago, and come with open hearts and friendly feelings, a large number of them men of fame and high rank. The third greeted the announcement of the fact that on the first day of the gathering more than six hundred Americans were inscribed on the rolls. This recognition afforded to our name must have flattered the national pride of every one of us who were present.

This hearty welcome was more than I had mustered the courage to expect, for, indeed, Americans visiting Europe on such occasions as this labor under certain difficulties. Europeans do not quite understand our country, its political and social configuration, or its scientific attainments. If that is so even in Great Britain, both race and language being identical and mutual intercourse more frequent, how much less can we expect to be known on the continent. Besides, it is not always the best political, social, and scientific class of our fellow-citizens who travel extensively, and, though it is not the crowd of the *profanum vulgus* that ought to tell in the estimation of the best spirit of their country, it does so tell. Now, the majority of medical Americans they know in Europe, and particularly in Germany, belong to one of two classes—either they are *bona fide* students whom, being mere foreigners, they consent to matriculate even without the preliminary education rigorously insisted upon with their own young countrymen, or they are our young doctors who pass a few months or a year in European laboratories and clinics for the sake of special studies. It is these that are also the occasional participants in their national associations, where, nobody else being present, they are naturally considered the representatives of American medicine. Our best men travel but little and talk less. Indeed, some of those who were most fit to represent us in the congress kept in the rear, modest and retiring. Besides, the great opportunity America might have had to present to the view of the world whatever there is great and progressive in American medicine appears lost, for in the very number of the *German Medical Weekly* which was published in the week of the congress you could, in the history of previous congresses, read the statement that the Washington congress was unfortunately a failure, for which all of us, being Americans, are held responsible. Moreover, though English is read by a great many of the best men in Europe, the knowledge of our language is not so general as to insure a wide acquaintance with our literature through anything but the uncertain channels of extracts or translations. Nor are even these well selected. We are all aware that our medical journals are of as unequal rank as our schools, and not infrequently will you find a journal which is deservedly unknown among us, but is quoted in Europe under the impression that it is a fair representative of American medical literature. Nor is the treatment Europeans receive at our hands always very courteous or considerate. The editorial remarks of a great New York weekly were quoted as unkind, inasmuch as the efforts to make the congress international and Berlin a neutral ground for the whole world did not appear to be appreciated with us. It must be admitted, though, that they did not deem that Western journal worthy of serious consideration which spoke of the Tenth International Medical Congress as a congress of snobs, and advised every one of the forty thousand practitioners of the Mississippi Valley, "every one superior to the leaders of the congress," to stay at home.

Public opinion is often made or unmade by trivialities, sometimes indeed by personalities of an inferior nature. It was a source of complaint in Berlin that an American who had been honored with the request to represent our country by delivering one of the great addresses had neglected to see to it that his refusal reached the Committee of Organization in anything like due time. The proverbial courtesy of Americans was found wanting, and that at a time of feverish excitement and overwork. Such occasions are the very opportunities for those formerly Europeans who try to rise in their own estimation and that of their former countrymen by detraction of us, for there are those who do not immediately succeed, when they, our guests and future fellow-citizens, arrive among us, in impressing us with their superiority, or in being appreciated by us as they are by themselves, or in obtaining at once a lucrative practice and professional positions and honors. It is they who pay for the hospitality proffered by our country with shoulder-shrugging insinuations and pitying remarks upon our crudeness and inferiority, our "mob rule," our "civilized barbarism," instead of aiding in the realization of the national and cosmopolitan aims of the medical profession and science.

Nothing is so small as not to have some effect. Unfortunately, there is still so much national jealousy everywhere that faults and shortcomings in your neighbor beyond the boundary line are easily believed in, and slanderers and libelers are always busy. When I arrived in Germany a newspaper article was shown me which was concocted by a sectarian practitioner, formerly in New York, who detailed the inferiority of American medicine, schools, and

practice to the horrified sanctity of the German public; and in the very week preceding the congress hundreds or perhaps thousands of pamphlets were distributed in Berlin for the avowed purpose of insulting us and making us uncomfortable. The pseudonymous author, who appears to have lived, or to live, in Chicago, says, among a great many other things, the following:

"In reference to the transatlantic gentlemen, nothing is more out of place than indulgence. American tolerance, so frequently extolled, exists for Americans only. When about to travel they leave it at home. It is almost always the result of ignorance, indifference, and bad conscience. As the average American never cares for the history of a science, the majority of the transatlantic members of the International Congress are totally unacquainted with European institutions, labors, and scientific methods and their aims. Nevertheless, every one of these gentlemen carries a paper in his pocket, easily compiled, wherewith to resuscitate the obsolete science of Europe." In the same sheet the man asserts that forty-two per cent. of all the doctors in Chicago are professed abortionists, and a great many followers of "Christian science."

Some of the great Germans with whose names every one of us is perfectly familiar denied being in any way influenced by such rubbish; but then again it was through them that I had to learn of a New York specialist, a fellow of this Academy, who was reported to have availed himself of his personal intimacy with the officers of the Associated Press for the purpose of having his congress paper served at the breakfast tables of a million of American households on the day of its delivery. That was a week before the opening.

Still, though they are human on the other side of the Atlantic, as we are on this, the facilities of communication have become such as to assure those wishing to see and know the truth that the time when American medicine was merely receptive and imitative has long passed by, and that we have entered the arena as co-operating peers. They were anxious to have us and secure a large American attendance. In order to accomplish that end, the general committee appointed an American committee which was to enlist universal sympathy in our country. No time was to be lost, and the first ten medical men who expressed their willingness to serve were appointed. The territorial jealousy, one of the most marked of American littlenesses, which was expressed in some journals, obliged me to explain publicly, in the May meeting of the Association of American Physicians, why that committee consisted of Stewart, Fitz, Lusk, Draper, Hun, Pepper, Busey, Osler, and Peyre Porcher. Will the Western gentlemen who found fault with the committee, and heaped vituperation on the mode of its composition, tell us that the names selected did not deserve the honor conferred upon them, or that there are better ones among us? Does American medicine begin at the Alleghanies or the Sierra? Or will you, gentlemen of Ohio, Mississippi, or Nevada, tell us which of the forty-four stars of the glorious flag is the one you claim as yours? Yours are the forty-four; so they are ours. Are your minds not big enough, your hearts not large enough, to embrace the love of and the pride in the whole flag of America?

A further proof of anxiety to secure the co-operation and good-will of the Americans was given by the Berlin committee in this, that they insisted upon one of the public addresses in the general meetings being delivered by an American. Weir Mitchell having declined in time and courteously, and Osler not being within reach, I was telegraphically directed to select an orator. The choice of Horatio C. Wood was heartily approved of in Berlin and elsewhere. Again, a few have asked why could not a New Yorker have been honored with that commission? That question is answered by some other queries: Do you know of a better man? Is America bounded by the East and North Rivers? And, lastly, has New York forgotten that she can afford to be courteous and generous?

More. A few brief weeks before the meeting of the congress the American orthopædists expressed the desire that there should be a separate Section of Orthopædics. When I, then already in Europe, was notified of that request by the chairman of the Orthopædic Section of this Academy, and expressed my fear lest it might be too late to make arrangements for that change, I was by returning mail informed by the Secretary-General that the request had at once been granted by the Committee of Organization, on the ground that my countrymen must know best what suited them and their scientific labors.

The organization of the congress was not completed without the election of an American vice-president, John S. Billings, and an American, Mr. Allen Starr, as one of the two English-speaking secretaries, and a large number of American vice-presidents of sections. And, lastly, when on the third day of the congress, and in the second general meeting, the hour grew late and the audience melted under the hot sun, Dr. Wood's address was, out of consideration for the Americans, postponed to be the first topic of the third meeting, though the hour and arrangements and printed preparations had to be changed accordingly.

All this was meant, and was believed to suffice, to make every American feel at home. If it did not succeed, it ought to have accomplished that end. But I have been told that disappointments have been keenly felt and complaints been uttered.

When an English paper was read, many have been reported to leave the room. Many essays were not read at all, some were not allowed the time required by the authors, some men would read beyond the legal limits. Such comments are natural, but so also are their causes. The unprecedented number of papers offered at a late date, and too courteously accepted, and some acoustic disadvantages of many of the audience halls, are among the causes of disappointments which are unavoidable in everything human. The experience of the past can furnish remedies in the future. However, when one man complains that he was not one among the five per cent. of members who could be admitted to the court reception in Potsdam, another that he had to pay for his share of the section dinners on the evening of Wednesday the sixth, proclaiming that matters were different in Washington, where no foreigner paid anything, it proves one of two things—either that there were those who went more for the incidental appurtenances of

the congress than for the congress, or that our national failing, which is a highly developed emotional hyperæsthesia, was rather demonstrative. I can assure those who are finding fault with the scantiness of their enjoyments that I know of some at least who neither shared in the entertainment in the City Hall, for which Berlin paid eighty thousand marks, nor danced at any of the five balls, nor imbibed the music and songs in eleven languages, and other beverages, at Kroll's, and—did not feel the worse for it the following mornings. If I have any fault to find, it is with the overflow of entertainments, the excess of generosity, the multiplicity of luncheons, dinners, and receptions, the waste of money in the vast number of public and private social gatherings.

If there ever were hosts spending unstintingly, aye, squandering money in the service of unlimited hospitality, they were the profession as a whole, and the single medical men of Berlin.

In connection with this fact, let me make a remark which is dictated by no caviling spirit, for I have too many reasons to appreciate the universal kindness and untiring hospitality of the great and gentlemanly members of the Berlin profession, who were bent on nothing but rendering the sojourn of the foreign guests comfortable and pleasant. I must here mention the names of Virchow, Bergmann, Waldeyer, Gerhardt, Henoch, and Leyden and his accomplished wife, the Chairman of the Ladies' Committee, and could name a host of others. Many of us found it impossible to respond at the same time to the requirements of actual congressional duties and the urgent demands of hospitable courtesy. In this also there are discomfort and loss for the individual member. But the matter has a very much more important aspect. An excess of social entertainments and the accomplishment of the end for which the International Congress is convened are incompatible at a certain point. Too many feasts interfere with legitimate work. The expectation of a good time may—if I can not say it does—invite the attendance of many, of hundreds, perhaps of thousands, who would not go for the sake of work. On the other hand, those who have gone for the latter are liable to feel sorely disconcerted. Thus it has happened—at least this disappointment can be held in part responsible—that the national associations have suffered from the persistent absence of those who do not wish to lose great opportunities; and that all over America, Great Britain, France, Germany, and other countries, there have been formed by dissatisfied men who place scientific work over any distractions, be they ever so pleasant, special societies, the objects of all of which ought to have been accomplished in the sections of the general bodies. It would be a sad development if the same tendency were to grow up in international congresses. At this very moment there are already in existence an international ophthalmological and an international otological congress. It would be the fault of the management of international medical congresses if other specialties or doctrines should follow the example for no other reason than the predominance of the social over the scientific element. If the latter ceases to rule, the great men of science will stay away, and the holiday-seekers and a few ambitious office-holders will remain. *Docet experientia.*

It is only a wealthy city and rich professional men who can entertain as Berlin did. For such hospitality as was displayed there you require large and generous hearts, ample and well-filled purses. There are but few communities like hers. If the habit of prodigality becomes persistent, we shall be received in future with misgivings on the part of our hosts, who must fear lest their efforts fall short both of the results of predecessors and of the expectations of the guests. Let these two calamities occur—viz., the absence of the best men of all nations and, on the part of cities and men, hesitation to request our coming—what will become of the international congresses?

And where is the prevention of the danger alluded to? Here: Let the social entertainments be reduced to a minimum. Then any city with ample hotel accommodations will be able to receive us, though we be thousands. Then those bent upon pleasure only will seek it elsewhere. Then the numbers will no longer be unwieldy and shapeless. Then the men looking for work and for the men who work will be eager to come and see and be seen, to teach and be taught.

The unprecedented success of the American Congress of Physicians and Surgeons, the first meeting of which was held in Washington in September, 1888, tells its own tale and exhibits the proof of what I have said. In my mind there is no doubt that its second meeting, in September, 1891, will be equally successful; its three days will be dedicated to work, and the official social entertainment limited to a plain subscription banquet. In that way neither the lawful work of the congress nor private intercourse and hospitality are interfered with.

It may appear invidious to muster the co-operative services rendered by the members of the different nations represented in the various sections of the congress. Still, as we generally have a good opinion of ourselves, we are not afraid of looking back at our own contributions to the scientific material that was furnished. When we do so, we have to admit, however, that but a small percentage of our seven hundred participated in the general work. It is true there was one who got himself delivered of quintuplets; fortunately, he had no equals, and he was not, as a medical journal reported, "taken in earnest." Still, there were a number of papers, not compiled, but original. The Orthopædic Section was American to a great extent. The Neurological had a very fair representation from our country. The Gynæcological and Pædiatric sections were not without American contributions. The Surgical was supplied with papers which were highly appreciated, mostly from the West. Indeed, there were but few sections in which no American took part, though there were some in which no active work at all was furnished by us. The most redeeming feature was the meeting of the combined Laryngological and Pædiatric Sections, in which the ingenious, painstaking, and successful efforts of O'Dwyer were heartily applauded.

After all, however, the labor performed in the sessions may be the principal, but is certainly not the only, object

in view. An English journal has said that "congresses are not instruments of research," and, still, the transactions of all are replete with it. It is true a congress is not so much meant for new discoveries as for the broad dissemination of facts, hints, and ideas. A man—not being ubiquitous—may not take away with him many things new, but what he carries home is a new stimulus and encouragement.

In the congress you saw a great many men whom you thought you knew, but, since you listened to them and watched them while you listened and took their measure, know better now. You saw and heard the living objects of your admiration, the molders of professional thought in all countries; discoverers, teachers, laboratory-workers, practitioners; those who, after hard work, create books by spontaneous generation out of their brains, and those who compile them out of their pigeon-holes; the eagles, the bees, and the moles—also the parrots and that class of envious cuckoos that "transfer other birds' eggs into their own nests." You found there was room in our great army for many men and many classes of men. You gathered encouragement from learning that even truly great men were still men and human, and that some degree of greatness was within the grasp of any man in town or village who would work for it intelligently, bravely, and honorably. All this is what a congress will teach those who consent to learn.

There is another lesson that is taught by a congress: The separation into twenty sections proves the endless and diversified branching of the grand old tree of medical science. Their working under the same roof, however, and under the same administration, their occasional combination for a common purpose, their gathering in general meetings, and their listening to the same addresses, with the same interest and profit—all this, in spite of the fact that some of the twenty appear to be threatened with the danger of degenerating into mere handicraft, proclaim louder than steeple bells that medical science is "one and indivisible, now and forever."

The congress conveyed to me, like its predecessors in Copenhagen and London, a great lesson and furnished an elevating spectacle. Imagine, those of you who have not been present, thousands of medical men from all parts of the world and speaking a dozen different languages, not perhaps endowed with the same erudition or mental or moral power, but moved by the same instincts and interests and assembling at the same call and for the same special purpose. The great and the lowly, the old and young, meet as brethren on the same platform, if not of equality, still of fraternity and solidarity. National jealousy and prejudice are shelved for at least a week, and the lesson is taught that brethren may live together peaceably under the same roof, an example to the nations of the future. The man and the man of science are appreciated and loved, though political adversaries. Applause takes the place of hisses. The contest is no longer against each other but with each other, side by side, arm in arm, with the same weapons of the brain and soul against the common enemy of science and mankind—viz., physical deterioration and social misery. Thus the cosmopolitan spirit of coming centuries is foreshadowed and initiated by the co-operation of the men arrayed in the army of the noblest of all sciences and professions. Therefore may no man who can prove an example to his peers in this or any other country, no man who can teach, none who can learn, none who can worthily represent his country in any capacity and do honor to America among foreigners—may no man, except for valid reasons, ever shirk his duty to attend an International Medical Congress.

THE MANAGEMENT OF FRACTURED LIMBS.*

By EDWARD VON DÖNHOFF, M. S., M. D.

When the proper method of avoiding the unsightly and mischievous consequences of bad management of fractures in the continuity of limbs seems to be shrouded in impenetrable mystery (?), the solution is often enough to be found, if rightly sought for, in the ignorance of certain radical principles, and growing out of this an element of harmful fearfulness on the part of the medical attendant. To my mind, a more rational answer than this can not, in a majority of instances demanding it, be found to account for the wooden and unsymmetric appearance, if not permanently compromised usefulness, of many limbs issuing after treatment (?) for fracture from the hands of the surgeon. The more deplorable is this state of things since one may speak in this connection with greater propriety than in most others of definite rules of management, these being based upon notably constant reparative phenomena, so uniformly attendant upon injuries of this class and in such thoroughly accredited guise that, barring unessential *contretemps*, each variety of the two grand divisions of fractures of limbs—that involving the shaft only and that affecting the joint—may be successfully treated by the thence deducible formulæ. When it is borne in mind that books on general surgery, and even those specially devoted to fractures, fail to definitely indicate the proper length of time during which it is necessary to maintain uninterruptedly a fixed apparatus upon a fractured limb, and added to this other neglects of detail, and the tendency on the part of many practitioners to follow literally and tremblingly what of inexplicit rules (?) they may find laid down in such works; and, further, the infrequent and wavering use made by many of the most palpable fruits of induction—any adverse feeling as to the seasonableness of the following remarks will, it is hoped, be mollified.

Ordinarily, the broad proposition that when a patient who has sustained a fracture of a limb or a joint leaves the care of the surgeon, the functional capacity and symmetry of the erstwhile injured part should be *very nearly* if not *quite perfectly* re-established, is thoroughly logical if the proper methods of management have been observed, and

* Read before the New York County Medical Association, October 20, 1890.

provided there were no constitutional influences to militate against the repair. This is especially true of simple fractures resulting from indirect violence, and only exceptionally untrue of compound fractures—*i. e.*, when the modifying element is of the most serious nature permitting of the conduct of the case as one of fracture. So that in our day, to quote a great Nestor of surgical philosophy, "a simple fracture, or one convertible in time to this form, should rather be considered a serious inconvenience than a fearfully hazardous malady to the unfortunate." Even age is a comparatively insignificant factor of prognosis, formidable (?) only in that it bears upon the likelihood of acquired diathetic influences which may become active as local interruptions. In this connection it is a remarkable fact that fractures occurring in the bodies of pronouncedly strumous young individuals in whom analogues of histological senile changes are frequent are not discernibly influenced by the existing diathesis except in much debilitated subjects, or such as have already existing active bone disease. Active syphilis, congenital or acquired, is much more apt to exert an adverse influence in either young or older persons. Upon the whole, there seems to be less danger of total or partial failure of treatment, so far as union of fragments and symmetry of limb and function are concerned, from diathetic influences or acutely developed local causes or temporary diseased conditions of the body at large than from faulty mechanics or dilatory manipulation. The largest proportion of rational failures are in epiphyseal fractures, necessitating special consideration of muscular attachments in the mechanism of apparatus to be adapted to the injury. This variety embraces, of course, fractures of the femoral and humeral head and glenoid cavity and the olecranon and coronoid processes. It is perhaps as excusable to fail in satisfactorily dismissing a case of this sort after ordinary treatment as it is inexcusable to abandon a case of simple fracture of the forearm or leg healed (?) with a remaining incurvature or excurvature, or, what is rarer, however, a pseudarthrosis. It is equally unpardonable to dismiss a case in which, through faulty management alone, there remains what ought never to have been permitted to develop—a fibrous ankylosis of joints, whether involved in the fracture or not. Such conditions often enough are the source of seriously modified or quite abridged usefulness of a whole limb and the utter helplessness of the sufferer.

It is just here that an absence of that knowledge of detail, so rarely vouchsafed the student of text-books and auditors at didactic lectures, is most poignantly felt and too tardily admitted to be the basis of the success of acknowledged superior skill. A half-dozen or so of ankylosed elbows, wrists, hands, etc., in one's surgical repertoire should, it seems, be a sufficiently effective means of suggesting the propriety of a change in the erstwhile practiced methods. And yet there are those within the sound of my voice who have a much longer score to their credit (?). This is, of course, not the only field of surgery in which such evidences of unfitness exhibit themselves, as witness the salutary revolution effected in operative surgery generally by the inducted, methodical attention to detail of its most modern and most brilliantly successful school. Such revolution could only have been possible in the face of such acknowledgedly criminal negligence as it has swept out of existence. It is said of Lister that, during the time when the antiseptic (?) spray was by him considered a *sine qua non* of success, he dismissed an otherwise competent assistant for having, during a very short interval—an operation by Sir Joseph being under way—permitted the spray to cease. Whatever the justice of this incident, surely the offense was not so reprehensible as a neglect on the part of the surgeon to use the proper precaution against the establishment, quite unnecessarily, of a stiff joint, or a crooked limb, or a much shortened one; and yet English surgery is remarkably, though not exceptionally, free from distinct rules of prophylactic practice in this regard. From a text-book as much sought and consulted as Erichsen's, it is impossible to learn when a fracture dressing is to be finally removed, or when passive motion of a fractured elbow may be safely begun, etc. Indeed, no text-book is known to me in which this information is distinctly and ætiologically imparted, and only in comparatively recent times have occasional articles appeared in medical journals looking to the establishment of the "treatment of fractures" upon a physiological and scientific basis.

When the surgeon of a decade since is confronted with his then faulty technique, such as a failure to securely arrest hæmorrhage from the smallest bleeding point, or his failure to adapt the closure of a wound to the known requisites underlying the physiological union of cut surfaces, or inattention to the imperative details of drainage, and last, but not least, failure to secure all the hygienic and other physiological addenda of wholesome physical comfort to the patient he wished to safely tide over a surgical danger, he stands confessed an erstwhile unthinking votary of dogmas which, while they embodied the spirit, failed to impress the literal necessity of attention to the smallest details of truths underlying, as chiefest corner-stones, the grandeur of modern surgical achievement.

There is no less a need of attention to detail, in order to secure proper results in the management of fractures, than there is of assuring similar desiderata in other fields of practice, and these are by no means easier, but rather more difficult of establishment here than elsewhere. Besides being of the first importance from a medico-legal point of view, the perfect success in the treatment of fractured limbs is essentially tributary to utilitarian philanthropy. The treatment of a fracture should begin with a correct understanding of the mechanical history and topography of the injury. In order to secure this, it is, in my opinion, necessary, in the majority of cases, as a matter of both safety and accuracy of adjustment—the most essential initial step to success—to anæsthetize the patient, at least in every instance where muscular resistance to effective manipulation is expected, or a doubt as to the exact line of fracture exists. I should positively make no conclusive (?) examination in any case of fracture of the shoulder, elbow, wrist, hip, knee, or ankle joint without the exhibition of an anæsthetic, unless, indeed, it were possible (?) to secure through the will-power of the individual or by apparatus—these resources to be substituted only under cir-

cumstances contra-indicating the use of anæsthetics—such a passivity of muscles as to assure a satisfactory exploration. The examination should note the amount of enlargement growing out of infiltration of the surrounding soft parts with serum or blood, also the probable amount of fluid —probably blood—lying in immediate contact with the fracture, and the degree of displacement of fragments and the direction of it.

We will assume the study of a simple comminuted fracture of the elbow. The diagnosis being complete, the limb should now be scrupulously cleansed. Begin the first dressing of a fracture by fixing the replaced fragments—*i. e.*, the site of the fracture first—with a plaster-of-Paris roller, adjusted over suitably arranged batting or other cushioning of available material, in only sufficient quantity to prevent painful or undue pressure. This roller is permitted to harden somewhat before the succeeding ones are applied, as its evident purpose is to secure the fragments in the position given them by the operator in such a manner as to prevent their slipping during the subsequent manipulation. The limb is now swathed as usual and the plaster bandage adjusted, beginning at the distal extremity over the first applied roller and including the shoulder in a spica. In fractures of the elbow I have for a long time preferred a pose of about 110°, because of the muscular equilibrium thus attained and the greater usefulness of the limb in this position to a laborer should (?) the joint become ankylosed.

If great restlessness is expected at this time, the anæsthesia may be prolonged for a few moments, which will suffice for the hardening of the plaster, especially if it is rubbed with powdered alum. When the patient is thoroughly conscious and the surgeon convinced of his complete comfort, the first dressing may be regarded as properly adjusted; as soon after this time—ordinarily from two to three days—as the more or less complete recedence of the swelling is indicated by the general sense of comfort, and the evidences elicited by careful percussion of the plaster casing, this should be carefully divided into two equal halves longitudinally, and the upper half carefully lifted off without in the least disturbing the limb. The exposed cotton is then smoothly teased away, observing the middle line in the process, and so the arm is bared quite perfectly for all purposes of inspection.

If the swelling has, as is most likely, receded and the shapeliness of the limb is suggestive of good apposition of the fragments, the removed half of the dressing should be, after trimming down, reapplied and fastened in position with a cheese-cloth roller snugly applied, and the patient allowed to rest undisturbedly during the ensuing two or three days. At the end of this time the patient should be again anæsthetized and the dressing carefully removed altogether. Passive motion should be slightly effected at the elbow. The shoulder and wrist joints, as also the fingers, should be thoroughly moved. The limb is then lightly swathed in batting, including the wrist but not the shoulder joint, which is held in position by a few turns of ordinary sewing thread. The whole is then covered with two leather splints previously cut and shaped, by measurement.

Birch-tanned saddle-skirting, which I prefer, is made quite soft by dipping it quickly into very hot water (160° to 170°), and so becomes as adjustable as papier-maché. The splints are quickly and accurately molded to the limb, and held in position with turns of sewing thread, to be directly followed by a cheese-cloth roller. In a few hours this case will be found to be quite bone-like in hardness, and having, of course, the exact shape of the limb. On the day following, the upper half is lifted off and slight passive motion made at the elbow and wrist. Everything progressing favorably, the slight remaining swelling of the limb will decrease visibly day by day, and the edges of the leather may be trimmed accordingly to preserve a close fit. Each disturbance of the dressing must be followed by its careful readjustment. On the eighth or tenth day I remove the whole casing and fix its two halves together, at their posterior border, with a series of points of waxed-end sutures; their anterior edges are provided with shoe-lace hooks. Thus a perfect and reliable boot is secured. The case or boot is then replaced and laced in position, after the proper passive motion has been practiced. During the succeeding four to five days the bandage is regularly removed by the surgeon and readjusted after passive motion, which by this time will be possible to an extent very nearly simulating the normal area. Now the patient may be instructed to leave off the boot during the day-time and readjust it only when about to retire for the night, so that he may be protected against injury from involuntary motion during sleep. After arising and bathing the limb with tepid water and subjecting it to gentle friction with a towel, the patient should be required to make voluntary motion to the limit of his comfort in imitation of all the normal motions of the limb; during the day he should carry a small round object in the hand of the injured limb and manipulate it for a time; he should also be required to occasionally make complete pronation and supination. At the end of the fourth week the individual whose injury has been treated as above described can be safely dismissed from attendance.* He will have been sufficiently educated by this time in the management of his condition, and will, at the time of his dismissal, be finally instructed to keep up the nightly adjustment of the apparatus during the following two weeks. Bathing, massage, motion, etc., are to be likewise systematically practiced.

The foregoing is a typical case exemplifying my practice during the past fifteen or sixteen years, during which time I have seen no failures in the treatment of similar or other kinds of fracture managed in this fashion. I have during that period induced many surgeons to practice the method, and have only heard words of commendation. Some years since, a considerable number of cases (one hundred and sixty-five) of fracture, very varied in character and taken from the practice of colleagues who kindly contributed their experience with this method, were collated and tabulated

* In fractures of the lower extremities the patient should not be permitted to bear his weight continuously on the injured limb until the close of the fifth week, lest he incur the danger of refracturing it or producing a curvature at the point of fracture because of the still relatively soft condition of the callus.

by myself and reported to the State Medical Society of Kentucky. This statistical table embraced many cases of complicated and comminuted fractures at the elbow, and also a number of intracapsular fractures at the hip. In no instance did an adverse or at all questionable result obtain, though many cases were of the gravest and most difficult nature. Many were instances of surgical fracture by the Macewen operation.

A number of intracapsular fractures (hip) were also contained in the list. The average duration of active treatment and attendance by the surgeon, in all the cases thus recorded, was twenty-eight days.

In no case was there remaining any deformity, atrophy, or vestige of fibrous ankylosis, or marked abridgment of voluntary motor capacity—surely a very encouraging summary.

From an analysis of the supposititious case preceding, we may formulate rules of practice which are applicable to the management of every form of simple fracture of the long bones and joints of the upper and lower extremities, and are based upon such unvarying (?) attendant physiological reparative phenomena that they are quite self-evident as well as safe guides. In the management of comminuted simple and compound fractures the added difficulties of the situation are occasionally such as demand nice discriminative mechanical tact during the arrangement of the fragments at the time of the *first* dressing; and for the rest, a thorough appreciation of phenomena attendant upon the repair of bone injuries complicated with contused or similar lacerations of adjacent soft parts, the significance of which varies in degree of importance as an element of prognosis as well as a never-to-be-overlooked guide in the very first steps to be taken, dependent upon well-understood probabilities in this connection.

As to the time of beginning passive motion of a fractured joint and those necessarily included in the first fixation apparatus, it is only requisite to remember how readily stiffness and, a little later on, ankylotic appearances develop in temporarily confined joints, to appreciate the necessity of taking advantage of the earliest moment of safety to interfere and interrupt fibrous formations between the articular surfaces; such interferences need, fortunately, to be very slight indeed, and neglect now will afterward constitute an almost, if not quite, complete nullification of our best (?) efforts in other respects. No phase of a clinical fracture history is of graver significance than this matter of possible fibrous ankylosis. It is this, too, which evolves those phenomenal appearances of atrophic and paretic developments, especially often associated in the late history of the so-called graver forms of fracture, which are wont to excite our commiseration when, alas! it is too late to aid the victim. Experience, based upon an observation of a great number and variety of cases, including many comminuted and compound and otherwise complicated fractures of the extremities, has satisfied me perfectly that it is safe and best, ordinarily, to leave off "fixation apparatus"—except as a protection against untoward involuntary acts or such as might occur during sleep—at the earliest practicable moment—*i. e.*, about the fourteenth or fifteenth day, a time at which the "pin" and "ensheathing" callus and periosteum have been reformed and the new structures are sufficiently firm to support the "part" thoroughly against all prospectively reasonable chances of displacement; but of course not against *great* violence, or, in the case of the lower extremity, against the uninterrupted effect of the superimposed weight of the body, as in walking, etc. But I have frequently exhibited patients to medical societies, after a Macewen operation done for the correction of deformity of the thigh or leg, able to stand without artificial support as early as the twelfth day. These tests were quite sufficient to demonstrate the feasibility of my proposition, and I can not therefore too strongly emphasize my belief that it is unnecessary and baneful—promoting, as it does, atrophic changes and retarding the reacquisition in numerous directions of interrupted functions even in many cases of the simplest form—to maintain fixation by artificial means after a natural and safe provision against displacement of the fragments is assured.

It is of the first importance to effect an accurate and exact adjustment of fragments, as well in fracture of bone as in divisions through the soft parts, as certainly the most valuable desideratum underlying the prompt union of divided structure. This is more or less constantly possible to expert and painstaking hands, and is always (?) followed by the best, strongest, and most rapid cementing of the breach. It is only fair to add, for the benefit of those who would witness for themselves the results described in the preceding paragraphs and than which *I* have seen few others during the past fifteen or sixteen years, that it will not be permissible in the premises to overlook or slight the least detail in the management of their future cases.

THE TREATMENT OF LATERAL CURVATURE OF THE SPINE.*

By HENRY LING TAYLOR, M. D.,
NEW YORK.

In spite of untold labor devoted to the subject of lateral curvature by able men, we still seem to lack, for the ordinary forms of this affection, a scientifically observed and well-digested clinical history, a satisfactory theory of pathogeny, and a thoroughly rational treatment.

There are, no doubt, diversity, multiplicity, and complexity of causation in these cases, but the theories so far advanced either fail to explain or conflict with observed facts, such as the following:

1. Most delicate children with weak spinal muscles, leading a sedentary, precocious, and intense life, and habitually assuming faulty attitudes, do not develop lateral curvature.

2. Some vigorous children, leading an active, out-door life, and whose spinal muscles seem as strong as or stronger than the average, do develop lateral curvature.

3. Right-handed people sometimes develop scoliosis, with the dorsal convexity to the left.

* Read at the meeting of the American Orthopædic Association, Philadelphia, September 17, 1890.

4. Most children with considerable differences in the length of the lower extremities and consequent pelvic obliquity do not develop a rotary lateral curvature.

5. A patient with shortness of the right leg (without joint or muscle trouble) and with the pelvis sloping to the right may develop a curve, with the convexity to the left, in the lumbar region.

6. Lateral curvature with extreme rotation may develop with the spine in the horizontal position. (See specimen of mammalian spine in the Museum of the College of Physicians and Surgeons, New York.)

What is the reason that, out of a hundred pale, flabby, undertrained and overstrained children who assume faulty attitudes, and some of whom have flat feet or crural asymmetry, only a few develop scoliosis?

In estimating the effects of treatment it is necessary to know that many cases of lateral curvature are self-limited, or at least do not progress very far even without treatment. I am constantly discovering mild or moderate forms of scoliosis in adults in the course of examination for other troubles, and some of them have never suspected the existence of the spinal affection. On the other hand, it is even more important to know that very many cases do grow worse unless carefully managed, and some have a strong tendency to go on to extreme deformity, even under persistent treatment.

When beginning cases are brought for an opinion, certain data—such as the height, chest expansion, and Roth's horizontal dorsal contour—should be noted, and the patients should be examined once in a few months to see if the deformity increases. In the mean time explicit directions are given for the regulation of the mental, physical, and social life. It seems clear that regular habits, moderate exercise, stated complete rests in the daytime, plenty of fresh air, and an open-air life, with the avoidance of physical, mental, and emotional forcing and strain, are a vast help to these patients, and I believe that the rational employment of these rational means does arrest the progress of the curvature in many cases.

I have observed several instances of city school-children with moderate osseous curves, but who had never worn braces, who improved notably during a three months' sojourn in the country, with a natural open-air life. On the other hand, I have seen severe curvatures develop in sturdy children brought up in the country under apparently just as favorable conditions. Attention to these points, however, is always imperative and often sufficient in the earlier and milder cases.

The backache and spinal tenderness so sedulously sought by the inexpert are not properly symptoms of lateral curvature. They may be symptoms of a system below par, or of nervous or spinal weakness, and are often accompanied by headaches and other local and general symptoms. A few of these patients have lateral curvature in addition, and a moderate proportion of scoliotics have headache and backache as an expression of their general condition of health. The rib pains and other pains of some of the extreme cases belong to a different category. These patients with backache—usually anæmic and with impaired digestion, nutrition, and elimination, and a faulty nervous and blood distribution—are much benefited by systematic attention to mode of life, general and special exercise, rest, diet, bathing, and mental and moral hygiene, and, if they at the same time happen to be suffering from scoliosis, these indications are all the more clear and urgent. While lateral curvature is not caused by general lack of vigor, it is much more apt to develop in such constitutions when the other necessary factors are present; when it is developed, it acts as a constant drag and strain upon the economy through imperfect equilibrium, overworked muscles, and crowded viscera, according to the grade of the affection. By careful attention to the measures mentioned, for which it is necessary to give specific directions and to secure the co-operation of the patient and her family, and the use of special exercises, we are nearly always able to improve the general health and vigor

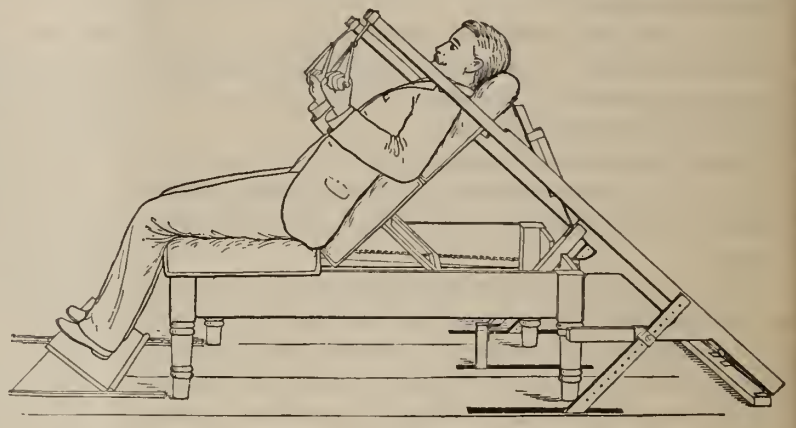

Fig. 1.

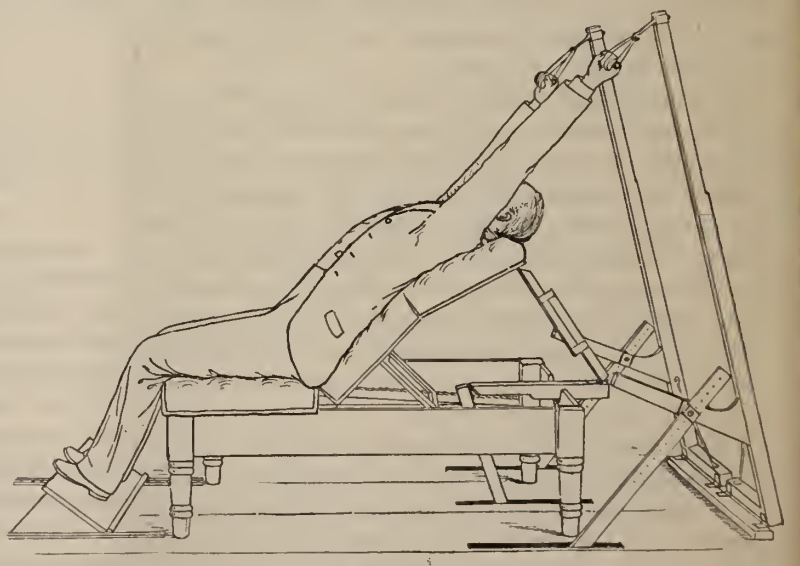

Fig. 2.

of our patients, give tone to the muscles, relieve backache when present, increase endurance, and often improve the attitude and carriage of the body.

As chest power and capacity are threatened or already encroached upon, we give special attention to respiratory exercises, by which means we also favor oxygenation of the blood and improvement of nutrition and circulation, but are careful to avoid overtaxing a system in many instances already delicate and tired. To fulfill these indications we have found nothing so useful as certain specific exercises, mainly passive, adapted by Dr. C. Fayette Taylor from the system of Ling. The apparatus called the respirator (Figs. 1 and 2), elsewhere described,* actuated by steam-power, and giving sixteen deep respiratory movements a minute, is prescribed for nearly all our scoliotic cases requiring special treatment.

By means of another power apparatus we give alternate right and left lateral flexion, forty-six times a minute, of the trunk through the loins, the patient lying on the back. This increases lumbar flexibility, strengthens the muscles about the waist, and acts on the abdominal viscera.

Another useful exercise is taken while the patient lies on a couch made of two halves hinged in the middle, and so contrived that the body may be flexed and extended at the waist against a balancing weight, the upper and lower half being fixed at choice (Fig. 3).† This and the preceding are excellent exercises for improving abdominal circulation and increasing peristalsis, and the latter strengthens the back and abdominal muscles.

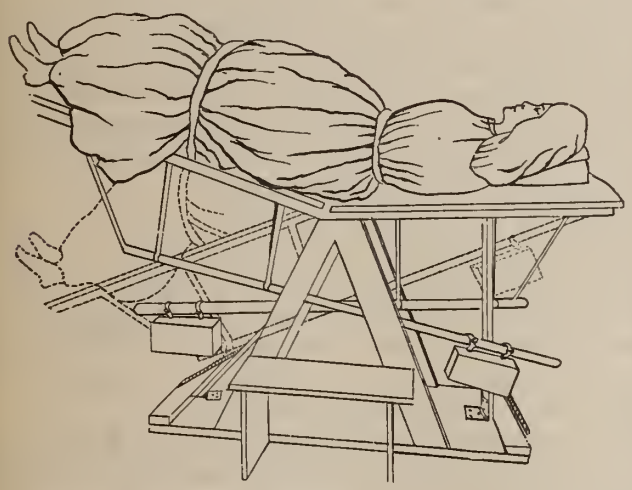

Fig. 3.

To attack the deformity directly, we use lateral suspension from the hands in an apparatus consisting of a vertical, adjustable upright, hinged near the middle and carrying a reversible pad for pressure upon the convexity of the main curve, and a hand-piece for grasping. When the upper part of the apparatus is drawn over to the side, the patient is lifted from the floor, and the weight of the body forces the pad against the projecting ribs in the direction of the longest diagonal of the chest. At the same time the concave or contracted side of the chest is expanded by the wider excursion of the corresponding arm (Fig. 4).*

Fig. 4.

In addition to these movements, I have lately given to some of my patients certain active free exercises similar to those recommended by Roth.

We shall be in a better position to judge of the value of prescribed exercise in the treatment of scoliosis when we have more exact information in relation to the special physiology of muscular movements, and particularly of associated and co-ordinated movements. We know well that the contraction of any given muscle or group involves the contraction of many other muscles; in fact, determines a change greater or less in nearly every muscle and tissue of the body; but we need to know how simple and combined movements affect carriage, attitude, and the normal and abnormal positions of the spinal column, and how these effects can be varied to produce specific results.

Whatever factors may be present in addition, we certainly have to do with a problem in balancing. The spinal column sustains the weight of the trunk, but the muscles balance the column. The varying tonicity of the trunk muscles, responsive to changes in position and strain, keep the unstable column delicately poised, but slight causes may destroy this harmonious action, especially in the period of muscular instability and spinal flexibility common in adolescence (and more marked in girls than in boys), and throw continued strain on feeble parts; and further pro-

* The Therapeutic Value of Systematic Passive Respiratory Movements. *Medical Record*, May 4, 1889.

† From *Spinal Irritation*, by Dr. C. Fayette Taylor, p. 23. W. Wood, 1870.

* Described and figured on page 98 in *Theory and Practice of the Movement Cure*, by Dr. C. Fayette Taylor, 1860.

gressive changes will take place in the lines of least resistance.

It should be remembered that the center of gravity of the human body lies in the upper lumbar region, in most cases to the right of the median plane,* which might help to explain the greater frequency of primary lumbar curves and the preponderance of the left lumbar and right dorsal position, since in balancing the body there would be a tendency to bring the upper lumbar vertebræ to the left of the median plane, in order to place the center of gravity over the middle of the base line.

The observation has been made† that scoliosis is rarely seen among people who have been trained from childhood to carry loads on the head, like the peasants of some parts of Europe and of some of the West India Islands. I have been struck with the firm, erect carriage of fencers. Both fencing and the carrying of loads on the head are, in part, exercises in the fine and diffused muscular adjustments of balancing, and contain hints for the training of these cases.

Is it not possible that scoliosis, pre-eminently, so far as we are informed, an affection of civilized countries and cultivated classes so called, is fundamentally but one expression of the faulty, one-sided training of certain areas, with corresponding starvation and atrophy of others that these conditions impose upon muscles and mind?

As to mechanical support to the spine, in addition to the measures already spoken of, my position is that it is of substantial benefit when properly managed in selected cases, and my aim is never to employ it whenever the patient can

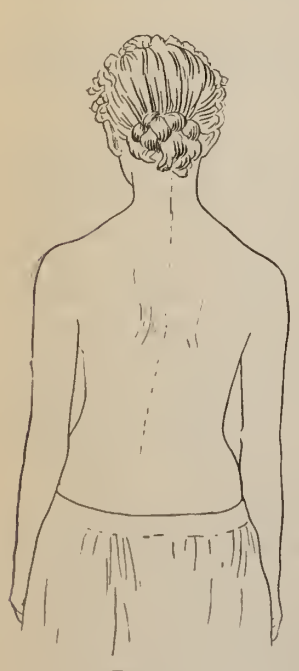

Fig. 5.

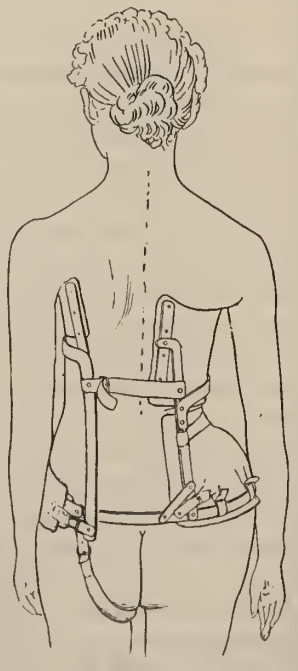

Fig. 6.

do as well without it. This is a matter for observation and judgment, but in practice only a certain proportion of the severer cases are so treated. The aim of mechanical support should be not only to correct or hold the spinal deformity, but also to relieve cramped, stretched, and atrophied parts of undue strain by the restoration, so far as may be, of a more normal dynamical equilibrium.

For this purpose we use a light steel apparatus acting on the principle of lateral leverage, and worn only during the daytime, while the weight of the body is acting upon the spine.

The details vary in each case according to the indications, but a general idea of a common form employed and its action may be gathered from the cuts (Figs. 5 and 6), which were taken, with slight modifications, from photographs of the same patient, and within a few minutes.

A light steel band, closed at one side by a strap and buckle, passes around the hips above the level of the trochanters. To this an H-shaped, braced steel upright, which carries a broad band of leather on its upper end for pressure against the projecting ribs of the convexity, is fixed at right angles, and the whole is held in position by a flexible hip-piece fitted over the ilium of the side of the prominent curve, and buckled to the hip-band. This hip-piece serves as a fulcrum when leverage is applied by the perineal strap, which unites the two ends of the hip-band, passes under the leg on the side opposite the main curve, and is regulated at the buckle behind. The counter pressure on the side of the trunk opposite the main curve, higher or lower, as is mechanically more advantageous in the particular case in hand, is given by a similar firm leather band supported on the upper ends of a separate steel H-piece, which is completed below by a strap over the hip. The two H-shaped side-pieces are fastened together in front by an adjustable bowed steel U-piece, with a key-hole at each end which slips over a screw head about half way up the front bars of the H-piece (Fig. 7); behind, by a strap and buckle, by which the pressure of the apparatus is adjusted. By working from fixed points on the pelvis (hip-piece and perineal strap), the swaying to one side of the trunk *en masse*, which is often one of the main difficulties, is directly opposed (Figs. 5 and 6). This apparatus requires the nicest judgment in design and the greatest care in its adaptation, and must be modified from time to time to meet special requirements, as the case progresses. It is only a tool, like a violin, which is capable of being manipulated to produce definite results by one who is skilled in its use. Here, as everywhere in orthopædy, it is a question of method not means, principles not rules, and men not machines.

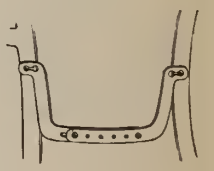

Fig. 7.

I have but briefly mentioned some of the methods we have found useful, fully realizing that there is much more to learn than we now know in regard to this difficult and important subject; but, in spite of our defective knowledge on many points, we expect good results in the milder and earlier cases, and gratifying amelioration in all but the worst of the more advanced cases, provided we can secure hearty and full co-operation.

NOTE ON A NEW SYSTEM OF EXACT DOSAGE IN THE CATAPHORETIC USE OF DRUGS.

By FREDERICK PETERSON, M. D.

In a paper of mine, published in the *New York Medical Journal*, April 27, 1889, there are figured two cataphoretic electrodes devised for the anodal diffusion of drugs through the skin. The great drawback, until this present moment, has been the difficulty of accurately regulating the amount of drug introduced. For this purpose rather complicated electrodes have hitherto been required, and even these have been unsatisfactory. I have recently found, however, that all difficulties are easily obviated by the use of a new and exceedingly simple method. Messrs. Waite and Bartlett have made for me a cataphoretic electrode of metal. Instead of covering it, as before, with sponge, the ordinary metal surface is overlaid with a thin disc of platinum, and around the edge of this is placed a narrow rim of soft rubber. The drug to be used is put drop by drop upon a disc of ordinary tissue paper cut to fit the disc of platinum. Filtering paper or linen cloth may be used instead of tissue paper. A disc two or three centimetres in diameter will hold from one to four drops of the solution. When the medicated disc is placed upon the metal surface of the electrode, and the latter then applied to the skin, it is evident that there is a thin capillary layer of the drug in solution exposed to the cataphoretic power of the anode, between the electrode and the skin, and that the quantity of the drug used may be accurately estimated. The current is allowed to flow if desired until the medicated disc becomes perfectly dry. In this way we may drive in one or more drops of chloroform, methyl chloride, ether, ten-to-twenty-per-cent. solutions of cocaine, a one-per-cent. solution of helleborin, solutions of iodide of potassium, corrosive sublimate, aconitine—in fact, any drug we wish to employ in this manner; and at the same time we know exactly how much we are using.

To further simplify the method, I have had medicated cataphoretic discs prepared by a pharmacist for use at any time, for the paper discs may be charged with any amount of a watery solution, and, the water being allowed to evaporate, they may be kept on hand indefinitely. It is only necessary to add two or three drops of water to the disc in administering the drug by electricity.

Mr. Otto Boeddiker, the apothecary, of 954 Sixth Avenue, has made for me, and is prepared to supply any one with, the following cataphoretic discs: Discs of menthol, 2 grains; of helleborin, $\frac{1}{25}$ grain; of strychnine nitrate, $\frac{1}{32}$ grain; of iodol, 2 grains; of corrosive sublimate, $\frac{1}{8}$ grain; of cocaine hydrochloride, $\frac{2}{5}$ grain; of aconitine, $\frac{1}{64}$ grain; of potassium iodide, 4 grains; of mercury succinimide, $\frac{1}{4}$ grain; of lithium chloride, 4 grains.

Pineapple Juice for Diphtheria.—"It is reported that the negroes of Louisiana frequently employ pineapple juice in the treatment of diphtheria; and this treatment is alleged to be successful."—*Druggist's Circular and Chemical Gazette.*

A TYPHOID SEQUEL.*

By J. C. CROSSLAND, A. M., M. D.,
ZANESVILLE, OHIO.

On April 25, 1889, I attended Blanche R., a girl of eighteen years, in confinement. Her labor was natural but prolonged. According to her statement, she had always had a rather weak back. In the latter months of her pregnancy she did considerable hard and heavy labor. During this period she complained of pain, principally in the left shoulder, which after parturition seemed to alternate in the shoulders. I saw her the next day after confinement, and her condition was satisfactory. On the 7th day of May I was called to see her, and found her suffering from pneumonia, involving the entire left lung. The lower lobe of the right lung was subsequently affected. This disease was grave and eventuated in suppurative pneumonitis, which continued for several weeks. In the latter part of this trouble the patient was seized with typhoid fever. She lay sick of the fever about eight weeks. The fever, entailed upon such a grave disease as pneumonia, as you would readily infer, brought the patient nigh unto death—so near that a physician of large experience, who saw her several times in consultation, made a fatal prognosis each time. However, the patient made an incomplete recovery. She so far recovered as to be able to go about the house and help administer medicine to the other members of the family, five in number, varying in age from twelve to sixty-five years, all of whom were sick with the fever. A few weeks after the patient was able to leave the bed she began to experience severe pain in the dorsal and lumbar regions of the spine and along the sides of the chest in the region of the sixth to the tenth ribs, inclusive. There was tenderness to pressure in these regions, with slight elevation of temperature, pain on any motion of the back, a sensation of pressure against the back, and an aching pain in the lower extremities. This condition of things persisted, with remissions and exacerbations, until November, when the patient began to notice loss of sensibility, first in the right foot, then in the left. Loss of motion and a staggering gait were next observed. In the language of the patient, when she tried to put her foot in one place, it would go somewhere else. This loss of sensibility and motion increased and extended as far as the waist. There was spasmodic action of both the extensor and flexor muscles of the lower extremities, also of the lumbar muscles; while she was in the dorsal decubitus there was a tendency to tonic spasms of the flexor muscles. These spasms would last sometimes for an hour, and then be followed by spasms of the extensor and erector spinæ muscles. This condition of things persisted until there was almost complete paraplegia. Spasmodic muscular action existed throughout the trouble. The bowels were in no way affected. There was no retention of fæces and no involuntary stools. For several weeks the urine was greatly diminished, and was voided at times at intervals of twenty-four hours. No bladder trouble, however, arose from this urinary abnormity. There was marked emaciation of the lower extremities. In the mean time, while the spinal trouble was advancing to the paralytic stage, the sternal ends of the sixth, seventh, eighth, ninth, and tenth ribs, and their cartilages, became very prominent, projecting outward and upward in such a manner as to form a support or table upon which the mammary glands rested. After the more acute inflammatory symptoms had somewhat subsided, I did not see the patient until the paralysis had become well marked.

In the early stage of the spinal trouble my treatment con-

---

* Read before the Hildreth District Medical Association.

sisted of occasional narcotics, liniments, sinapisms, and blisters over the spinal column, tepid baths, occasional small doses of calomel, rest in the recumbent posture as much as possible, and as highly nutritious a diet as the patient's humble circumstances would allow. In other words, I followed the line of treatment recommended by Flint for the affection which I suspected. After the stage of paralysis had been reached, I gave small doses of mercury. I tried iodide of potassium, which disagreed and was withdrawn. Strychnine also disagreed. In fact, this patient had so many idiosyncrasies that it seemed there was little to be hoped from medicines. Fortunately, the patient's appetite and digestion remained fairly good, and much reliance for a time was placed on the *vis medicatrix naturæ*.

After the paralytic symptoms had reached their height, a galvano-faradaic battery was used two or three times a week. About the 1st of April and some three or four weeks after beginning the use of the electricity the patient began to improve. At the present time she is almost entirely recovered. She has recently walked as far as a mile at one time. The costo-cartilaginous deformity still exists, but is not so marked. There is an anterior curvature in the dorso-cervical region, which renders the spinous processes of the first four dorsal vertebræ very prominent. In the lower dorsal region there is a slight posterior curvature, with some tenderness in that region. The left side of the chest is diminished in size and asymmetrical. The left shoulder droops, but there is no real lateral spinal curvature.

I have not been able to find, in the literature to which I have access, any similar condition of things following typhoid fever. The most light I have been able to obtain on the subject is in an article in the *New York Medical Journal* of November 30, 1889, by Dr. Gibney, of New York.

This case, in its early stage, presents a striking similarity to one or two of Dr. Gibney's cases. Possibly, with fair advantages, in this case the disease might have been arrested and brought to a more speedy termination. It was not until I had read Dr. Gibney's article that I made the diagnosis of periostitis complicated with chronic spinal meningitis, and to him I am also indebted for my lucky prognosis.

I am inclined to the opinion that the pneumonia is accountable, in whole or part, for the costo-cartilaginous deformity, and possibly it may have been a factor in the production of the spinal trouble.

I have been actuated in the report of this case not by the desire to claim any merit for the result, for the patient's poverty was so great and her advantages were so few that medicine and surgery were of comparatively little avail to her, but for the purpose of recording what seems to me a good result from a series of grave and rare affections.

It is a good illustration of the healing power of Nature.

ANEURYSM OF THE ARCH OF THE AORTA.*

By C. N. HAMMOND, M. D.,
BENTLEY CREEK, PA.

On April 2, 1890, I was called to see Miss D., aged twenty-five years, who was suffering from neuralgic pains in her right shoulder and arm. She informed me that she had been suffering about two weeks, and could get no relief from any remedies she had used. She said she had had a similar attack some two or three years before, and had had some form of fever. Her family history was very obscure, she being a foundling.

During my examination I observed her to cough, which induced me to examine her lungs, and I discovered dullness over the right supramammary region. There being no rise of temperature, I thought there might be some caseation or latent congestion. I prepared her remedies which I thought were indicated, and left her. The following day I called and found her feeling, as she expressed herself, "much better."

On April 6th I was again summoned, and found her suffering severely with those neuralgic pains; and she said her right hand and arm would get numb and cold at times. I examined her right lung, and found pulsation and increased dullness where it was on the 2d. I suspected an aneurysm and examined her carefully; but for the most part I got negative results. The radial pulses were synchronous, of equal rhythm and volume, and I could get no "aneurysmal bruit." The tumor, if such it was, was not in the region of any large artery, being too low down for the subclavian and too far to the right for the right carotid or aorta; and I came to the conclusion that it was an intrathoracic tumor, which must come in contact with some large artery that caused it to pulsate, and that its pressure on some plexus of nerves caused the neuralgia of which she complained. I gave her tonics and opiates to keep her comfortable, and ordered five grains of iodide of potassium three times a day. On the following day her condition remained much the same; but, on examination, I heard a bruit, which was absent on the two succeeding days. Her temperature at each visit was about normal. Respiration 20 to 22, with no dyspnœa, and pulse 80.

On the 9th, Dr. W. C. Wey, of Elmira, was called in consultation, and he found the symptoms about as before related, except that there was no bruit. Dr. Wey, with a hypodermic needle, punctured the tumor and found the contents to be blood, but still, as other symptoms were absent, could not be positive of an aneurysm, and the diagnosis was still unsettled as between an intrathoracic tumor and an aneurysmal one. At my visit on the 11th I again heard the bruit, and, from the examination with the hypodermic needle by Dr. Wey on the 9th, I was convinced this must be an aneurysm. Her temperature on the 10th and 11th rose to 100° F.; she was feeling considerably worse, and I advised her to keep her bed. (Up to this time she was about the house most of the time during the day.) At my examination I found the area of dullness about three inches and a half in diameter, nearly circular, and the center about an inch above the right nipple.

At my visits on the 12th and 13th I found her more cheerful and feeling better. Temperature, 99°; pulse, 80; respiration, 22. Bruit quite clear. On the 14th I saw her about 4 P. M., and found her very hopeful; her appetite was improving very much, and she said she felt stronger and rested with less opiates. I found the area of dullness had diminished to about two inches, and I flattered myself that the tumor was being absorbed. I got no bruit. About two o'clock that night (the 14th) she awoke and called for a drink, joked and laughed with the person who waited upon her, and lay down and went to sleep. About 6 A. M. on the 15th, on going to her room, she was found dead, and, to all appearance, had been dead for several hours. An autopsy was held that evening, which revealed an aneurysm given off from the ascending portion of the arch of the aorta, which had ruptured, thereby causing immediate death, also hypertrophy and dilatation of left ventricle of the heart. There were also tubercular deposits in the right lung, which was much atrophied and hepatized. The left was nearly normal. Dr.

* Read before the Bradford, Pa., County Medical Society, September 2, 1890.

Huff, Dr. Colgrove, and Dr. Voorhis, of Wellsburg, N. Y., were present, and assisted at the autopsy.

The treatment throughout was with tonics, iodide of potassium (which was increased to ten grains three times a day), and opiates.

In reviewing this case, the peculiar phases to me are that I only got the bruit at times, while at others it was absent; also its location. I will add, its shape was something like a pear, the body or fundus of which reached to the right mammary region, and it touched the chest wall only at this point. There was no necrosis observed, and its apparent diminishing in size (perhaps) was its receding from the chest wall by gravity from her keeping in a recumbent posture. The case was a very interesting and instructive one.

A CASE OF MORPHINE POISONING TREATED WITH NITROGLYCERIN.

By A. T. SPEER, M. D.,
NEWARK, OHIO.

C. R., aged seventeen, had been afflicted with disease of the hip joint for two or three years, and, becoming despondent because he could not go to school with his companions, took six grains of sulphate of morphine with suicidal intent at 8 P. M., September 23, 1890. His condition was not noticed until 10 P. M., when, as he could not be aroused, physicians were summoned and efforts made at once to overcome the effects of the morphine. Presuming that the morphine had all been absorbed, the stomach-pump was not used. Atropine—one thirtieth of a grain hypodermically every two hours, he being unable to swallow strong coffee—was injected in large quantities *per rectum* at short intervals. The galvanic battery was vigorously applied. One sixth of a grain of atropine in all was administered, the last dose at 6 A. M.

I was called in consultation at 8 A. M. the following morning. On examining the patient, I found him almost completely cyanosed, pulse 160, respiration 40, temperature 101°, loud mucous râles so as to be heard in the adjoining room, abdominal respiration only, pupils widely dilated (from atropine). Dr. C. H. Stimson, who had charge of the case and who met me at this time, said he had done all he could, but had failed to arouse the patient in the least. I gave an unfavorable prognosis; in fact, I did not think the patient would live more than an hour or two.

Dr. Stimson said he had some of Wyeth's tablets of nitroglycerin which he had thought of using as a last resort. It occurred to me at once that it might be of benefit, from the remarkable results produced by it in poisoning from illuminating gas. We decided to try it, and gave him at once one fiftieth of a grain hypodermically. We waited an hour and repeated the dose. In a few moments I directed him to be turned on his side. Very soon there was a long, full, thoracic inspiration; in about half an hour the patient vomited freely and became conscious. We gave him a hypodermic of one one-hundredth of a grain of nitroglycerin, after which he went to sleep, slept quietly two hours, then awoke and was all right, with the exception of a violent headache, the effect of the nitroglycerin.

I have reported this case in the hope that it may induce others to try the nitroglycerin in poisoning by morphine. I am fully satisfied that without its use the patient would have died.

Correspondence.

LETTER FROM DUBLIN.

The Introductory Lectures.—The Presidency of the Royal College of Physicians.—The Royal Academy of Medicine.—Military Sanitation in Ireland.

DUBLIN, *October 23, 1890.*

THE introductory lectures at the various medical schools and hospitals in Dublin, at the commencement of the winter session, are diminishing in number yearly, and very properly, as they are not only in the vast majority of cases useless to the student, but an irksome and unthankful task to the unfortunate lecturer. There is no regularity in the delivery of these addresses; for example, one was given at Sir P. Dun's Hospital by Professor Bennett on the 1st inst., and the inaugural address at the Adelaide Hospital will not be delivered until the 27th inst. Professor Bennett's excuse for an address was that, as some new wards were opened, the occasion was selected more as an advertisement than for any other reason. He pointed out that the medical and surgical staff returned twenty-five per cent. of the fees paid by students for clinical instruction to the hospital; a generous concession adopted by no other general hospital in Dublin. Some of the surgeons and physicians of our city hospitals have said that they served without fee or reward, and that none of the funds of the institutions with which they were connected went into their pockets. This is true to a certain extent, but all the same the students' fees, amounting to twelve guineas each for the nine months of attendance, are divided among the staff. I see that it is proposed to amalgamate some of the Cork hospitals, and the same suggestion has been made in reference to some of the smaller Dublin hospitals, but the great difficulty which exists is the objection—and a very natural one it is—that many physicians and surgeons would have their services discontinued, and thereby lose their fees. For if several small institutions were amalgamated, the larger institutions then constituted could manage very well with a much smaller staff than the aggregate number at present doing duty in the various hospitals.

On St. Luke's Day, the 18th inst., Dr. J. Magee Finny was elected president of the Royal College of Physicians of Ireland for the ensuing year, and at the termination of his year of office will be eligible for re-election. I can not speak too highly of this distinguished physician, and the fellows of the college could not have nominated a better candidate for the high position of president of their college.

The eighth annual meeting of the Royal Academy of Medicine in Ireland will take place on the 31st inst., when the report for the past year will be submitted and the officers for the various sections appointed. The president of the Academy is Dr. Samuel Gordon, this being his third and last year of office.

The sanitary condition of almost all the barracks in Ireland might be improved, and, as the subject has been brought under the notice of the Government, a sum of £900,000 has been allocated by the authorities for the purpose of making the necessary alterations. Lord Wolseley, the new commander of the forces, is at present on a tour throughout Ireland inspecting the various barracks, and his recommendations will have great weight. The Government has appointed an army sanitary committee, which consists of seven members, and the only non-army man appointed is Sir Charles Cameron, M. D., the efficient medical officer of health for the city of Dublin. All questions referring to the expenditure on barracks will come before the sanitary committee, who will be presided over by Sir Redvers Buller, V. C., K. C. B.

THE

NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by D Appleton & Co.

Edited by Frank P. Foster, M. D.

NEW YORK, SATURDAY, NOVEMBER 15, 1890.

THE ETHICS OF BOOK REVIEWS.

The ethical relations between the editor of a periodical, his staff of reviewers, the publishers, and the authors of books are somewhat complicated. Without attempting to treat of them at all exhaustively or methodically, we may jot down a few statements that may prove interesting to the various classes of persons concerned. In reviews, as in all other editorial matter, a well-ordered journal is an impersonal entity; the views expressed in it are not to be taken as necessarily reflecting the editor's notions as an individual merely, and so he may conscientiously insert a review differing decidedly in tone from the impression the book may have made on him—he has put it into the hands of a person whom he believes to be competent and fair-minded, and he will hesitate before "changing the politics," so to speak, of a review written by such a person. Nevertheless, he will on some rare occasions feel constrained to do so, and in such instances he will realize the advantages to all concerned of the practice of publishing reviews unsigned. There seem to us to be some other advantages in that practice. It shifts the responsibility from the reviewer to the editor, who from his longer training and more varied experience is better fitted to assume it; and it relieves the reviewer of any suspicion of having colored his article in accordance with either his known admiration of the author or his dislike for him. If reviews are to be signed at all, we think they should be signed with the writer's full name, for we have known a severe review to provoke resentment against a man who was not its author, simply because it was signed with initials identical with his.

Books should be reviewed solely on their merits, without regard to the author's praiseworthy or reprehensible performances not directly pertaining to the book. Of course they should be reviewed in a spirit of fairness—fairness not only to the book, but also to the readers of the journal, who are entitled to the actual truth as to a book that they may think of buying; it seems to us inadmissible to say of a book that "it will prove of great practical assistance to the student and to the practitioner" when both the editor and the reviewer know that that is not the case. This consideration, however, need not run counter to the general principle that it is one's duty to say the best of a book that its character will allow of. It is well to avoid exaggerated statements, such, for example, as that the book under notice is "the best treatise on the subject in existence." There are very few works of which that can be said in strict truthfulness; of various books on the same subject, each is likely to have some points of excellence not to be found in the others.

The foregoing relates chiefly to reviewers. As to authors, they would not be human if they were neither elated by laudatory notices nor depressed or irritated by those of a depreciatory tone. As a matter of fact, many of them crave adulation, and some are inclined to publish their resentment of the most reasonable adverse criticism. It is wise to curb both these propensities; certainly, the cases are very rare in which it is prudent for an author to make any public reply to an unfavorable review or even to an unfair or abusive one. The average reader is usually just, and it is not an easy matter to float a poor book with puffery, or damn a good one by misrepresentation.

The expectations of publishers are not always borne out in the fairest of reviews. Some of them expect too much—especially our American publishers, who are accustomed to more consideration than publishers get, for example, in France, where the standing announcement is to be found in many of the journals that every book of which two copies are sent will be acknowledged, and reviewed *if the journal has space.* But the conditions there are different from ours, and custom warrants our publishers in expecting reviews of all important works. Fortunate is the editor if he has not sent such a book to a person who can not be prevailed upon either to write the review or to return the book.

MUNK'S VISUAL CENTER.

In the *Bolnitchnaja Gazeta* for February 7th, Dr. B. A. Ratimoff gives the history of a case of gunshot wound of the head that he thinks supports Munk's ideas as to the locality of the visual center. A student, twenty-two years old, shot himself accidentally with a revolver. The ball entered the right side of the head at a point eight centimetres above the level of the external auditory canal and three centimetres behind it. Three hours after the accident the patient was perfectly blind, but he was conscious and able to give an intelligible account of his case. His general condition was good; the pulse and temperature were normal, there was no paralysis or paresis, and none of the senses but that of vision were impaired. The pupils reacted perfectly to light, and ophthalmoscopic examination revealed no abnormity of the fundus of either eye. The case was diagnosticated as one of lesion of the visual center, but doubt was felt as to whether or not the center on each side had been injured.

Trephining was resorted to, and the opening made in the skull by the bullet was found to be over a centimetre in diameter. A detached fragment of the inner table lay at the bottom of the wound. This, together with a mass of clotted blood, was removed, and the track of the bullet was explored carefully with the little finger and with a probe to the depth of four centimetres, but the missile could not be found, and the wound was closed, a drainage-tube having been inserted into it. This was on the 30th of September, 1889. By the 8th of October the patient's color-vision was perfect and he was able to read large letters at a distance of five feet, but the field of vision was found to be restricted in the left half of each eye.

The ophthalmoscope revealed no change except an imperfection of outline of the papilla of the right eye. The wound healed by first intention, but on the eleventh day after the operation it took on an unfavorable course; suppuration took place, the brain began to protrude, the power of sight decreased, and the patient suffered with intense headaches, restlessness, delirium, etc. On the 26th of November he was in a state of profound stupor preceded by alternate clonic and tonic convulsions. The stupor lasted for thirty-six hours, after which the speech was imperfect, there was paresis of the left side of the face and of the right upper limb, and vision was considerably impaired, with decided hemianopia. Ophthalmoscopic examination showed neuro-retinitis of equal degree in the two eyes, with moderate enlargement of the retinal vessels.

Death having taken place, it was found that the brain lesion was behind and below the posterior end of the fissure of Sylvius, in the postero-inferior occipital convolutions and in the part corresponding to the gyrus angularis. The brain in general was somewhat flattened on its surface, and the posterior convolutions were almost effaced. The dura was firmly adherent to the brain. The direction taken by the bullet had been from before and above on the right side backward and downward toward the left side, and the missile had destroyed the right visual center, passed through the longitudinal sinus, and entered the left visual center. There was an abscess at the site of each center, and the left one contained the bullet. The author thinks the features of the case confirm Munk's views as to the locality of the visual centers in the human brain.

MINOR PARAGRAPHS.

FATAL URÆMIA IN PERSONS APPARENTLY HEALTHY.

Dr. A. Westphal has described an interesting case, in the *Berliner klinische Wochenschrift*, of uræmic coma resulting fatally in a person apparently in a fair state of health. A young man, twenty-four years old, a joiner, was admitted into the hospital with sudden symptoms of difficulty of breathing, palpitation, swelling of the feet and ankles, and left-sided headache. His history was that of a feeble childhood, but without any serious illness. His feet had never swelled before, there had been no difficulty with the urine, and he had always been able to attend to his heavy work. He had not been a drinker, had not had syphilis, and had not been a worker in lead, and there was no ascertainable heredity. His face was swollen, his ankles were œdematous, and he was manifestly anæmic. The heart was hypertrophied somewhat, the sounds were weak but pure, with no accentuation of the pulmonary or aortic second sound. The pulse was small, regular, and without distinct tension. The urine was clear, acid, of the specific gravity of 1·005, with some albumin, hyaline casts, and leucocytes. There was nothing abnormal in the internal organs or the blood, but there was albuminuric retinitis. During the first few days of his treatment at the hospital the subjective symptoms lightened up decidedly, and he expressed himself as feeling quite well and gave the impression of being not seriously ill. The albumin remained at a small amount, and the quantity of urine varied between forty-five and fifty-eight ounces *per diem*, with a specific gravity of from 1·003 to 1·006. Five days after his admission, aphasic symptoms made their appearance as the forerunner of a severe uræmic attack, which set in with full force during the night; there were both clonic and tonic convulsions, frothing at the mouth, and loss of consciousness. The temperature rose to 103·8° F., the respirations to 60, and the pulse to 160, the cardiac dullness being increased to the right. Death ensued in deep coma from pulmonary œdema. On autopsy, both kidneys were found to be contracted, the right one being somewhat peculiarly displaced, being depressed and lying opposite the fourth and fifth lumbar vertebræ; it was extremely small, not more than two inches long by less than an inch broad, and appeared as a grayish-red fibrous mass with the blood-vessels small and not thickened; from these facts, as well as the microscopic appearances, the condition was judged to be congenital. The case was remarkable as occurring in a young person, without previous uræmic symptoms, who was apparently doing well when he fell into a state of profound coma and died in what was, so far as was known, his first seizure.

THE DISSEMINATION OF THE TYPHOID BACILLUS BY EDIBLE VEGETABLES.

An item regarding the alleged absorption of the typhoid bacillus from the soil into the juices of plants, where the fertilizing agent that has been used has been the night soil from city vaults, has had some currency in our sanitary periodicals. While the typhoid bacillus can at times be detected in the manure obtained from the scavengers, no competent observer has, we think, detected it in the juices of vegetables that have been manured with that substance. The use of such manure is, however, not wholly free from danger, and vegetables that do not pass through the process of boiling in their preparation for the table should be cleansed from all attached foreign matter with unusual care. In the neighborhood of many of our cities the cultivators of celery and other garden vegetables add liquid night-soil manure to their fields in order to advance the growth of their crops. A certain portion of this fertilizer can not fail to lodge on the leaves and stems of such edible plants as celery, which filth will not be all disengaged and washed away by the ordinary processes of cleansing for table use. Celery is especially mentioned because it is peculiarly apt to catch and hold the solid constituents of the scattered cess-pit manure, and in this dirt the bacilli of typhoid fever have been detected time and again.

THE OPENING RECEPTION IN THE ACADEMY OF MEDICINE'S NEW BUILDING.

This event, which is to take place on Thursday evening of next week, is sure to be one of great interest, and the occasion one on which both the Academy and the profession at large are to be congratulated. The reception committee consists of Dr. Alfred L. Loomis, the president of the Academy, Dr. Fordyce Barker, Dr. Francis Delafield, Dr. William H. Draper, Dr. Everett Herrick, Dr. Samuel T. Hubbard, Dr. Abraham Jacobi, Dr. William T. Lusk, Dr. Charles McBurney, Dr. Henry D. Noyes, Dr. George A. Peters, Dr. William M. Polk, Dr. Alexander J. C. Skene, Dr. D. B. St. John Roosa, and Dr. T. Gaillard Thomas. Dr. Loomis is to give an address of welcome, Dr. Edward L. Keyes will deliver the anniversary oration, Dr. Jacobi will speak on the subject of the library, Mr. D. Willis James will speak on The Influence of Scientific Associations upon Great Cities, Dr. John S. Billings, of the army, Dr. S. Weir Mitchell, of Philadelphia, and Dr. Reginald H. Fitz, of Boston, will make remarks, and Dr. Barker will add some words of congratulation. The admission will be by card only.

SCARLET FEVER WITH BUT SLIGHT PYREXIA.

In the *Münchener medicinische Wochenschrift*, Dr. Wertheimer and Dr. Beetz have reported four cases of scarlet fever without the usual pyrexia. In one case, that of a child of seven years, the highest temperature observed was 99·6° F.; the pulse was high, being from 116 to 120 during the greater part of three days. The other scarlatinal symptoms were well marked, and desquamation took place on the ninth day of the eruption. Another child had for its maximum temperature 100·6°, on the evening of the second day, with the pulse high as in the former case. In two of the cases the condition of the urine was noted as not albuminous. In the two others this symptom is not referred to. Dr. Wertheimer advances the opinion that the diagnostic importance of a continuous high pulse in apyrexial cases may be greater than has hitherto been recognized generally.

FATAL POISONING WITH MALE FERN.

An account of a case of this nature is given in the *Therapeutische Monatshefte*, in which death ensued upon the administration of two drachms of the ethereal extract of male fern, given as an anthelminthic. A child, five years and a half old, was given the amount named, within an hour and three quarters, in three doses. A portion of the tapeworm was expelled in an hour and a half; then vomiting set in, followed by somnolence, twitching, and trismus lasting ten minutes. Death took place in five hours after the last dose was given. At the necropsy there was found tuberculosis of the lungs and abdominal glands; and the unusual results from a dose of the extract, such as was given, were presumably due in part to the impaired resistance to the action of the drug incident to a physique broken by tuberculous disease.

THE ANATOMY OF THE ELEPHANT'S EAR.

The anatomy of the elephant's ear forms the subject of two notable papers in the *Transactions of the American Otological Society* for the current year, by Dr. Albert H. Buck and Dr. Huntington Richards. Dr. Buck's article is a revision of his description of two years ago, founded on further and less restricted observation of the specimen in the Museum of Anatomy of Cornell University. The three contributions, taken together, constitute a most valuable addition to our knowledge of the structure of the organ of hearing.

THE ACADEMY OF MEDICINE'S SECTION IN GENITO-URINARY SURGERY.

The first meeting of the Academy's new Section in Genito-urinary Surgery was held on Thursday evening, the 13th inst. The meeting was called for the purpose of electing officers, perfecting the organization, and listening to an address by Dr. Fessenden N. Otis. The standing of the gentlemen who are taking part in the work is an ample guarantee that the new Section will be creditable to the Academy and to the New York profession.

THE AMERICAN ASSOCIATION FOR THE CURE OF INEBRIATES.

This organization takes cognizance not only of alcoholic inebriates, but also of victims of the opium habit. It is to hold a series of monthly meetings in New York for the study of medical problems connected with these subjects. The secretary, Dr. Crothers, of Hartford, informs us that all the leading writers in this field are to present papers at the monthly meetings, and we do not doubt that they will prove of great utility.

THE ARMY SURGEON.

The *British Medical Journal* asks the army surgeons of England to keep in mind and cherish that motto of Ambroise Paré which says: "He who follows his profession for the sake of money and not for honor and knowledge will accomplish nothing." The British War Office, the *Journal* says, does not intend to divert the surgical staff from its highest aims.

ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending November 11, 1890:

DISEASES.	Week ending Nov. 3.		Week ending Nov. 11.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus fever	0	0	0	0
Typhoid fever	25	6	25	9
Scarlet fever	39	1	74	9
Cerebro-spinal meningitis	2	1	2	2
Measles	97	6	174	15
Diphtheria	54	17	96	29
Small-pox	0	0	1	0
Varicella	5	0	2	0

The Discussion on Rabies at the Academy of Medicine.—In the report published in the last issue of the Journal, the paragraph beginning on the first column of page 530 was an abstract of a paper by Dr. Hermann M. Briggs. As published, it appeared to be a portion of Dr. Dana's paper.

The New York Obstetrical Society.—At the annual meeting, held on October 21st, the following officers were elected: President, Dr. Joseph E. Janvrin; vice-presidents, Dr. Henry C. Coe and Dr. Robert A. Murray; recording secretary, Dr. Arthur M. Jacobus; assistant secretary, Dr. James R. Goffe; corresponding secretary, Dr. Augustus H. Buckmaster; treasurer, Dr. Lee J. Morrill; and pathologist, Dr. Calvin T. Adams.

The Society of the Alumni of Charity Hospital.—At a meeting held on Tuesday evening, the 11th inst., Dr. W. Oliver Moore was announced to read a paper on The Necessity for the Early Correction of Errors of Refraction in Children, and Dr. W. L. Carr to report An Interesting Case of Rheumatism complicated with Amygdalitis and Chorea.

The American Academy of Medicine.—The Constitution was altered at the last annual meeting, so as to admit, in addition to those possessing the degrees of A. B. and A. M., those who can present evidences of a preparatory liberal education equivalent to the same. Dr. J. E. Emerson, of Detroit, chairman of the committee on eligible fellows, will forward to any applicant copies of the amended Constitution and By-laws, List of Members, and other information as to the Academy.

The Medico-legal Society.—The programme for the meeting of November 12th announced papers as follows: The Legal Test of Lunacy, by Judge H. M. Somerville, of the Supreme Court of Alabama; The Insane Colony at Ghent, Belgium, by Dr. Margaret A. Cleaves; and Epilepsy as a Defense for Crime, by Professor John J. Elwell, of Cleveland, Ohio.

The German Universities.—Dr. Ernst Küster, of Berlin, has been appointed professor of surgery at Marburg, to succeed Professor Braun, who replaces Professor Mikulicz at Königsberg, the latter having been transferred to Breslau.

The New York Academy of Anthropology.—On Tuesday evening, the 11th inst., Dr. William C. Wile, of Danbury, Conn., gave a lecture before the Academy on the subject of Preventive Medicine.

The Brooklyn Surgical Society.—At the recent annual meeting, Dr. George R. Fowler was elected president, and Dr. H. Beeckman Delatour secretary and treasurer.

The Jefferson Medical College.—The *Medical News* announces that the chair of therapeutics and materia medica has been declared vacant.

Changes of Address.—Dr. W. H. Bates, to No. 131 West Fifty-sixth Street; Dr. Charles S. Collins, from Schenectady, N. Y., to No. 163 West 129th Street, New York; Dr. Robert C. Myles, to No. 25 West Thirty-sixth Street.

The Death of Dr. Albert Vogel, of Munich, took place on October 9th, in his sixty-first year. This eminent teacher, author, and social leader was a native of Munich, who had made his professional reputation at the University of Dorpat, where he spent twenty years, chiefly in the chair of pædiatrics. His book on *Diseases of Children* had passed through ten editions and had been translated into several languages; his eleventh edition had engaged his attention during the last year of his life, and was only recently announced. He was the recipient of many honors from the Emperor of Russia at the time of his retirement from Dorpat, and his return to Munich in 1886 was followed by many tokens of respect on the part of the authorities of his native city.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 2 to November 8, 1890:*

Crosby, William D., Captain and Assistant Surgeon, is, by direction of the Acting Secretary of War, granted leave of absence for four days. Par. 2, S. O. 259, A. G. O., Washington, November 5, 1890.

La Garde, Louis A., Captain and Assistant Surgeon, is detailed as member of board for duty in connection with the World's Columbian Exposition, and will report by letter to Major Clifton Comly, Ordnance Department, member of the board of control and management of the Government exhibit to represent the War Department. Par. 1, S. O. 260, A. G. O., Washington, November 6, 1890.

Bache, Dallas, Lieutenant-Colonel and Surgeon, Medical Director, Department of the Platte, is grauted leave of absence for one month. Par. 6, S. O. 82, Departmeut of the Platte, Omaha, Neb., November 1, 1890.

Arthur, William H., Captain and Assistant Surgeon, is relieved from duty at Fort Bayard, New Mexico, and will report in person to the commanding officer, Fort Grant, Arizona Territory, for duty at that post, relieving First Lieutenant William B. Banister, Assistant Surgeon. Lieutenant Banister, on being relieved by Captain Arthur, will repair to this city and report for duty to the commanding officer, Washiugton Barracks, District of Columbia. Par. 12, S. O. 254, A. G. O., Washington, D. C., October 30, 1890.

Wakeman, William J., Captain and Assistant Surgeon, is relieved from duty at Fort Bidwell, California, to take effect on the final discontinuance of that post, and will then report in person to the commanding officer, Fort Huachuca, Arizona Territory, for duty at that station. Par. 12, S. O. 254, A. G. O., October 30, 1890.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the week ending November 8, 1890:*

Edgar, J. M., Passed Assistant Surgeon. Ordered to the U. S. Steamer San Francisco. November 10, 1890.

Spratling, L. W., Assistant Surgeon. Ordered to the U. S. Steamer San Francisco. November 10, 1890.

White, Charles H., Medical Inspector. Ordered to the U. S. Steamer San Francisco. November 10, 1890.

Scott, Horace B., Passed Assistant Surgeon. Placed on the Retired List. October 31, 1890.

Ashbridge, Richard, Passed Assistant Surgeon. Surveyed and sent to hospital, Philadelphia, Pa.

Kennedy, R. M., Assistant Surgeon. Detached from Navy Yard, League Island, and ordered to U. S. Training-ship Richmond.

Atlee, L. W., Assistant Surgeon. Ordered to the Navy Yard, League Island, Pa.

Society Meetings for the Coming Week:

Monday, *November 17th:* New York County Medical Association; New York Academy of Medicine (Section in Ophthalmology and Otology); Hartford, Conn., City Medical Association; Chicago Medical Society.

Tuesday, *November 18th:* New York Academy of Medicine (Section in Theory and Practice of Medicine); New York Obstetrical Society (private); Medical Societies of the Counties of Kings and Westchester, N. Y.; Ogdensburgh Medical Association; Baltimore Academy of Medicine.

Wednesday, *November 19th:* Tri-State Medical Association of Mississippi, Arkansas, and Tennessee (first day—Memphis); Northwestern Medical and Surgical Society of New York (private); Harlem Medical Association of the City of New York; Medico-legal Society; New Jersey Academy of Medicine (Newark).

Thursday, *November 20th:* Tri-State Medical Association of Mississippi, Arkansas, and Tennessee (second day); New York Academy of Medicine; Brooklyn Surgical Society; Metropolitan Medical Society (private); New Bedford, Mass., Society for Medical Improvement (private).

Friday, *November 21st:* New York Academy of Medicine (Section in Orthopædic Surgery); Chicago Gynæcological Society; Baltimore Clinical Society.

Saturday, *November 22d:* New York Medical and Surgical Society (private).

Obituaries.

Dr. Henry Jacob Bigelow, of Boston, died on October 30th, at the age of seventy years. He had for many years, beginning in 1849, been the professor of surgery and clinical surgery at Harvard University and the foremost surgeon of New England. He was the son of an eminent physician, Dr. Jacob Bigelow, and was educated at Harvard, taking his medical degree in 1841. He was Boylston prizeman in 1844, with an essay on the subject of orthopædic surgery, and from that time began the publication of surgical papers that fixed his reputation for originality, capacity, and skill in his art. His development of the operation of lithotrity extended his repute abroad, and in 1882 the Academy of Medicine at Paris recognized his work in that department of surgery by the award of a prize. In that year he was made emeritus professor of surgery after thirty years of active duty in the Harvard University Medical Department. In 1886 Dr. Bigelow retired from active practice. His health had been failing for some time by reason of gastric and hepatic disease.

Letters to the Editor.

McBURNEY'S POINT.

198 Second Avenue, New York, *October 31, 1890.*

To the Editor of the New York Medical Journal:

Sir: In a most excellent paper, entitled A Contribution to the Study of Appendicitis, read before the New York Surgical Society, October 8, 1890, and published in the *New York Medical Journal*, October 25, 1890, Dr. Lewis A. Stimson refers in terms of the most appreciative and well-deserved admiration to a paper by Dr. Charles McBurney on Experience with Early Operative Interference in Diseases of the Vermiform Appendix,

read before the same society on November 13, 1889, and published in the same journal for December 21, 1889.

I quote from Dr. Stimson's paper: " . . . and, above all, he [Dr. McBurney] pointed out the means by which the presence of the disease [appendicitis] might be recognized at the very outset. Perhaps the most valuable result of the publication of Dr. McBurney's paper has been the readiness and certainty with which the disease is now recognized, and the wide extension that has been given to this addition to our diagnostic resources."

The addition to our diagnostic resources referred to is thus described in Dr. McBurney's paper: "And I believe that in every case the seat of greatest pain, *determined by the pressure of one finger*, has been very exactly between an inch and a half and two inches from the anterior superior spinous process of the ilium on a straight line drawn from that process to the umbilicus." As a proper recognition of the value of this symptom, Dr. Stimson very gracefully speaks of this point as "McBurney's point." And credit has certainly never been more justly awarded.

Dr. McBurney goes on to say: "This may appear to be an affectation of accuracy, but, so far as my experience goes, the observation is correct."

As far as my own experience goes, this is not an affectation of accuracy, and the observation is decidedly correct.

I operated in my first case of perityphlitic abscess on March 15, 1879. I had watched the case from day to day from its incipiency, eight days before the operation, and was particularly impressed with the persistence of a small point of greatest pain on pressure on a direct line drawn from the anterior superior spine of the ilium to the umbilicus. During the first days it was located exactly where Dr. McBurney describes it as invariably found—two inches from the anterior superior spine of the ilium. Later on, as the abscess pointed toward the surface, the point of greatest sensitiveness shifted along the above-described line toward the umbilicus, until it reached a point midway between the navel and the anterior superior iliac spine.

In all the cases of perityphlitis, or, as in the light of a better pathology we ought now to call them, of appendicitis, that I have encountered since, I have *invariably* noted the same condition. If the case was seen early, the point of greatest tenderness on pressure was found slightly to the outer side of the center of a line drawn from the anterior superior iliac spine to the umbilicus. If seen later, whether a decided tumor had formed or deep-seated induration was all that could be felt, the point of greatest tenderness had shifted to almost exactly the center of the above-mentioned line. The only variation that I have observed from this rule was in two or three instances *very* late in the disease, when the point of greatest tenderness had shifted in the direction of the thigh to half an inch below the center of the line between the umbilicus and the anterior superior iliac spine.

In reporting a discussion on the diagnosis between pyosalpinx and perityphlitic abscess, which occurred at a meeting of the New York State Medical Association on September 25, 1889, nearly two months before Dr. McBurney read his paper, the *Medical Record* for October 5, 1889, page 385, says: "Dr. Edebohls mentioned two diagnostic points in distinguishing between perityphlitic abscess and pyosalpinx. In the former the tumor lay midway beneath a line drawn from the anterior superior spinous process of the ilium to the umbilicus. The second point," etc.

The *New York Medical Journal* of October 19, 1889, page 442, quotes me to the same effect on this point. I should like to take this occasion, however, to call your attention to an obvious mistake on the part of your representative, who reports me in the same discussion as saying: "He [Edebohls] had often found a perityphlitic abscess six or seven days old developed enough to enable him to reach it, whereas a pyosalpinx could never be reached in that way." The sentence should read: "He [Edebohls] had *never* found a perityphlitic abscess until six or seven days old developed enough to enable him to reach it *per rectum*, whereas a pyosalpinx could always be reached in that way."

My experience with appendicitis embraces in the neighborhood of thirty cases. About one third of these were seen in private practice, the remaining two thirds chiefly in the wards of St. Francis Hospital. As gynæcologist to the latter institution, nearly all cases of abdominal tumor in the female are referred to me for examination and diagnosis. For many years past I have invariably taken the opportunity, when a case of appendicitis or perityphlitic abscess presented, to call the attention of the house staff to the value of the sign, now known a McBurney's point, in reaching a diagnosis. The patients, after a diagnosis of appendicitis was established, were transferred to the surgical division of the hospital.

This may serve to account for the fact that although I have seen and diagnosticated a fair number of cases of appendicitis, I have operated upon only three patients, all of them in private practice. The first of these operations took place on March 15, 1879, on the ninth day of the illness; 250 grammes of pus were evacuated and the patient recovered. The second occurred on January 7, 1884, on the seventh day of the illness; acute purulent peritonitis coexisted with the pericæcal abscess at the time of the operation, and the patient died. The third patient was operated upon on July 17, 1889, sixty-six hours after the onset of the disease; half a teaspoonful of pus was evacuated and the patient made a rapid recovery.

Others may, like myself, have long since learned by independent personal observation the value of McBurney's point in the diagnosis of appendicitis and pericæcal abscess. Indeed, it is scarcely probable that so striking a sign could so long have escaped the attention of all clinical observers. To Dr. McBurney, however, belongs the credit of having directed the attention of the profession to the point now justly associated with his name, and of having proved its diagnostic importance in appendicitis by a larger number of operations performed in the early stages of the disease.

In conclusion, I would be permitted to cite again from Dr. McBurney's paper, as expressing fully the result of my own experience on the subject, the following sentence: "Much greater tenderness at this [McBurney's] point than at others, taken in connection with the history of the case and the other well-known signs, I look upon as almost pathognomonic of appendicitis."

George M. Edebohls, M. D.

Saratoga, N. Y., *November 3, 1890.*

To the Editor of the New York Medical Journal:

Sir: Though firmly believing in the great value of "the McBurney point" in the diagnosis of appendicitis, the following case would seem to illustrate that, in case the patient is a woman, it is not always to be relied upon. On August 31, 1890, I was called in consultation to see Mrs. M., a widow, of good moral character and the mother of one child. The patient had been taken acutely ill on the 22d with headache, slight chills, pain in the lower portion of the abdomen, nausea, and vomiting, the pulse and temperature ranging from 96 to 100 and 99° to 101° F. respectively. This continued until the 29th, when all symptoms subsided to such an extent that the patient believed herself recovering. On the morning of the 31st, at nine o'clock, she was taken with a violent pain referred to the region of the uterus. This was accompanied by a very

severe chill, which did not cease until the attending physician arrived and administered morphine subcutaneously. At this time her pulse was 50 and her temperature 96° F. The previous history, as given me by her attending physician, was not concise or well defined, for the reason that, during the time the lady had been under his care—about two years—she had been somewhat erratic in her calls and to a great degree uncontrollable by her physician. Prostration, headache, dyspepsia, and pain in the lower portion of the abdomen were the principal symptoms of which she had complained during that period. Speculum examinations made at the physician's office at various times had shown chronic cervical endometritis. At 9 P. M. on August 31st I saw her for the first time. Lying on her back with the knees drawn up and supported by pillows, her face pale and anxious, with sunken eyes, she presented the appearance of being very ill. Her pulse was 130 and feeble, her temperature 102° F. An examination of the abdomen showed considerable distention and soreness over its whole extent. The McBurney point was exceedingly tender—far more so than any other spot on the abdomen. The left side was also tender at a point corresponding to the McBurney point on the right, yet to not nearly the same extent as the latter. This fact was very clearly made out and verified by the other physicians who were present at the operation, two hours later. A diagnosis of septic peritonitis was made and, though the chances of saving the patient's life seemed almost *nil*, an immediate operation was advised, as offering the only hope. To this, consent was readily granted. At 11 P. M., with the assistance of Dr. Grant, Dr. Inlay, Dr. Newell, and Dr. Swan, who concurred in the diagnosis of septic peritonitis, and in thinking it probable that disease of the appendix was the cause, the operation for the removal of that organ was done. On opening the peritonæum, thin pus and flakes of lymph escaped in considerable quantity. The appendix vermiformis, about three inches in length, was found lying along the lower side of the cæcum, and in a perfectly healthy condition. There was in its appearance no apparent departure from a normal state. Our light was poor—kerosene lamps—and the origin of the pus could not be discovered through the wound. The patient was in such an enfeebled condition that it was thought best to do nothing more except a thorough irrigation of the lower portion of the peritoneal cavity with warm Thiersch's solution. This brought away a quantity of pus and lymph flakes. A drainage-tube was inserted well down into the iliac fossa, stitches sufficient to retain the intestine were introduced, and the external wound was dressed with iodoform and sublimated gauze held in place by a bandage. After recovering from the anæsthetic the patient's pulse was 106 and her temperature 99° F. Two of the physicians remained with her during the remainder of the night, and, in conjunction with the nurse, one remained with her almost constantly until she died. After the first rally she grew more and more feeble and died thirty-four hours after the operation. Seven hours later an autopsy was had at which Dr. Grant, Dr. Inlay, and myself were present. On opening the abdomen, the small and large intestines were found plastered over with pus at intervals throughout their whole extent. The true pelvis was filled with pus and flakes of lymph. On sponging this out, the cause of the peritonitis became apparent in that the right ovary had been the seat of a large abscess that had ruptured into the peritoneal cavity. The ovary was lying directly underneath the caput coli. The left ovary was acutely inflamed, and enlarged from cystic degeneration. Both ovaries were covered with flakes of lymph. The uterus was normal in position and size. The tubes appeared to be perfectly healthy. No adhesions to any of the surrounding parts existed between the uterus, ovaries, or tubes.

I am induced to report this case mainly from the prominence given to the symptom, now very properly named by Dr. Stimson the McBurney point, in all the recently published articles on appendicitis; the apparently almost pathognomonic significance of this symptom; and the fact that I have not yet seen reported a case that has come to operation wherein this symptom existed in which the trouble has not proved to have been originally in the appendix. In the paper read before the New York Surgical Society on October 8th by Dr. Lewis A. Stimson, and published in the *Journal* for October 25th, Case XIX therein related has a general history common to both these cases. In that instance Dr. Stimson chose the median incision, thinking perhaps the peritonitis had another cause than appendicitis. In that case appendicitis was the cause of the peritonitis, while in the case here related no disease of the appendix existed. I might also add, my patient had had none of the diseases commonly said to be the cause of oophoritis—*i. e.*, gonorrhœal infection, puerperal septic absorption, acute rheumatism, or the eruptive fevers.

W. H. Hodgman, M. D.

MENTAL WORK AT GREAT ALTITUDES.

1316 Van Ness Avenue, San Francisco, *November 6, 1890.*

To the Editor of the New York Medical Journal:

Sir: Your *Journal* of October 25th contains a most interesting article of Dr. Eskridge, of Denver, Col.—Nervous and Mental Diseases observed in Colorado. As an appendix to it, allow me to call your attention to an article by Dr. M. Janssen in the *Semaine médicale*, 1890, No. 43, p. 366, entitled, Rapports entre l'effort physique et l'état intellectuel dans les hautes altitudes.

Let me give you some details about my ascension to the summit of Mont Blanc, between 4,400 and 4,800 metres in altitude. So far as I know, I am the only one who enjoyed, all through, the integrity of my intellectual forces; in fact, instead of becoming depressed, they were rather excited and more powerful, which I attribute to the absence of all physical effort during the whole expedition, for when I made bodily efforts during previous ascensions, I felt in a light degree all the troubles of which travelers complain in high altitudes. When ascending Grand Malets under great efforts, I felt this *mal de montagne* during the journey which followed the ascension. I could not think about my observations, nor carry out any intellectual labor; I felt too weak and nearly fainting; so that I had to inspire deeply and often to collect my thoughts. This time I rested four days in the hut des Bosses, and had an excellent appetite, though the fare was not my habitual one, and as long as I did not use up my bodily strength my mind remained clear, and after the first sleep I could perform mental work. Even at the top of Mont Blanc I felt no malaise and my intellectual faculties were in order; in fact, my excitement came from the inward satisfaction which I felt, so that I came to the conclusion that intellectual labor was possible in high altitudes as long as one abstained from all physical efforts.

Living on the Pacific Coast, *nous sommes toujours trop tard*, but better late than never. S. Lilienthal, M. D.

THE ACADEMY OF MEDICINE'S DELEGATES TO BERLIN.

110 West Thirty-fourth Street,
New York, *November 8, 1890.*

To the Editor of the New York Medical Journal:

Sir: In to-day's *Journal*, on page 518, you publish a brief editorial in which you say: "The programme for the meetin

[of the New York Academy of Medicine] on Thursday evening of this week consisted of reports of so-called 'delegates' to the Tenth International Medical Congress—eleven in number. It is well known that these congresses are not made up of delegates. It was therefore a work of supererogation for the Academy to appoint them, and to devote a meeting to their 'reports' seems to us to argue such a lack of legitimate material as ought not to be encountered at this time of the year."

In order to prove that this criticism is not based on facts, I have the honor of referring you to a circular of the American subcommittee (consisting of Dr. S. C. Busey, Dr. W. H. Draper, Dr. R. H. Fitz, Dr. H. Hun, Dr. A. Jacobi, Dr. W. T. Lusk, Dr. W. Osler, Dr. W. Pepper, Dr. F. Peyre Porcher, and Dr. J. Stewart) which was sent to and printed by a large number of American medical journals, and contained the following sentence: "Delegates of American medical societies and institutions, and individual members of the profession, will be admitted on equal terms."

This notice was based on the contents of an official letter received from the secretary-general, Dr. O. Lassar, dated February 28, 1890, part of which reads as follows: "It would please us very much if our invitation were given publicity by your national committee, with your recommendations. We imagine that could be best accomplished by a request directed to all the large societies to participate in the congress, either *in corpore* or by delegates." This letter, Mr. Editor, I shall take pleasure in submitting to you. Finally, I can assure you that a number of names contained in the official rolls of the central office had the word "delegate" added to them. A. Jacobi, M. D.

APHONIA CAUSED BY LEAD POISONING CONTRACTED BY THE ABUSE OF SNUFF.

69 West Eleventh Street, *October 24, 1890.*

To the Editor of the New York Medical Journal:

Sir: The following case is unique and may point a moral for some of our younger professional brethren: I was called to attend a young woman suffering from acute aphonia. She was a married woman, but of rather a loose aspect, so I had very little diffidence in making inquiries looking to a syphilitic origin of her trouble, but, to my astonishment, no such history could be evolved. On further inquiry as to her habits, I was informed that my patient "dipped"—*i. e.*, rubbed snuff into her gums. I examined her mouth, and, while doing so, was rather surprised to notice the signs of lead poisoning round the gums. I took a portion of the snuff to my office and examined it chemically, and found it *strongly adulterated with lead.* This was the key to the mystery. The local application of the lead had induced paralysis of the laryngeal nerve.

She was quite restored in two days by increasing doses of iodide of potassium. She stopped the "dipping" in a hurry, and has had no recurrence of her trouble since, a year ago.

Robert Ormsby, M. D.

Proceedings of Societies.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Meeting of October 20, 1890.

The President, Dr. George T. Harrison, in the Chair.

Omental Hernia.—Dr. T. H. Manley exhibited a large amount of omentum which he had removed from a patient recently operated upon. The man, now thirty years of age, had as a youth suffered from hernia, which had been cured by wearing a truss. It had given no indication of its existence until some six months ago, when he had noticed some protrusion on the right side. This had rapidly developed, and no mechanical arrangement could be adjusted that could be worn with comfort and efficiency. He had come to the hospital for radical relief. On cutting down, the sac was found to contain only omentum, which was removed, and the result had been so far satisfactory. The speaker thought that, as the cause had been merely omental, and this had been done away with, there was little danger of recurrence.

Ectopic Pregnancy.—Dr. Manley also showed a fœtus and secundines which he had recently removed. The patient, who had been treated by two other physicians before the speaker had been called, was found by him in a pretty serious condition. Her bowels were inactive, and there were suppression of urine, fever, and tympanites. On the left side there was a decided fullness, and, from the general condition of the woman, it was evidently a purulent formation. He cut down over this protrusion and came upon a large sac formed by recent adhesions of the intestines. This sac contained partly organized blood-clots in considerable quantity. The removal of these revealed a fœtus. The cord was found to stretch across the abdomen, the placenta being attached upon the opposite side to that on which the fœtus was lying. He established drainage through Douglas's *cul-de-sac.* The woman had made an excellent recovery so far.

Lichen Planus.—This was the title of a paper by Dr. L. D. Bulkley. (To be published.)

Dr. A. R. Robinson said that he could not agree with the speaker as to the ease with which a case of lichen planus might be diagnosticated. A well-marked case might be, it was true, but many times, without numerous observations, it would, he thought, be impossible. There were many cases of eczema from which it would be difficult to distinguish it, and only by watching the duration and course could a conclusion be arrived at. He thought too little was understood of the ætiology of the disease; when more was known, the treatment might be more efficacious. He considered it a parasitic disease. Treatment based upon this assumption gave fair results. He had once been opposed to the use of arsenic, but now believed that a large number of cases could be cured with it. This was no proof that the disease was not parasitic. He had made an error in the matter of dosage. The arsenic would be required in some cases to be administered in very large doses. Any statements to patients as to the time required for curing a case of lichen planus should be guarded.

The Treatment of Fractures.—A paper with this title was read by Dr. E. von Dönhoff. (See page 536.)

Dr. Joseph D. Bryant said that the writer of the paper had presented for consideration some suggestions decidedly unusual as to the treatment of fractures, and contrary to the methods advocated by teachers and text-books, as well as those employed in hospital practice and by surgeons at large. As to the diagnosis of fractures, he would state what he believed to be a proper principle in making it. The first step should be a careful comparison of the injured limb with the uninjured one. No surgeon should attempt to diagnosticate a fracture without making this comparison. He deprecated the plan of giving an anæsthetic for the purpose of making a diagnosis or seeking for crepitus. Its use as an aid in diagnosis was admissible only in the event of the existence of great swelling or for the better adjustment of the fragments. The necessity of the employment of early passive motion was not believed to be as important at the present time as in the past. In fact, it was common

nowadays for repntable surgeons to omit the employment of passive motion altogether during the treatment of the fracture, except, perhaps, in cases where the fracture communicated directly with a joint. At all events, there was good reason to believe that passive motion was not so essential to successful results as it had formerly been considered. The late Dr. Henry B. Sands, in a paper read before the New York Surgical Society, had emphasized this matter in a most admirable and convincing manner. There seemed now to be no doubt of the fact that the prolonged confinement of an uninjured limb would not result in any danger of ankylosis. He did not agree with the writer's conclusion, as drawn from Macewen's operation of osteotomy. The limbs of children when fractured always united very quickly, and there was no reason why a fracture of a bone of a lower extremity should not unite sufficiently in twelve or fourteen days, provided the fracture was a transverse one, to allow the weight of the bone to be borne upon the limb. However, he deemed it unwise that any such condition as this shonld be construed to mean that the appliances could be removed with safety to the limb. In the majority of fractures the dressings might be dispensed with in about four weeks, provided there was positive assurance against any unusnal violence that might disturb the union. He should not feel disposed, however, to tell a patient to remove an apparatus during the daytime and resume it at night. The qnestion was not what a doctor could do with a reasonable degree of safety, but rather what a patient could be permitted to do without incurring a danger of disaster. He could recall an instance, while he was an interne at Bellevue Hospital, in which he had removed the dressing from a thigh four weeks after a fracture at the middle third. On the morning following the day of the removal the patient had sustained a refracture, and this, too, had occurred without the patient having arisen from the bed, but was due, as he said, to his having turned over or in some way forcibly exerted himself during the night. The fact was the speaker should have kept the dressing on this patient's thigh for at least two weeks longer, which was done in the case of the refracture with complete success. He was sorry that the text-books did not lay down more definite rules as to how long special fractures should be confined in dressings. This omission was, however, not so great a fault as it seemed to the reader of the paper, since the time taken for bone to unite after fracture was pretty well determined, provided all other things were equal. The adoption of hard and fast rules in respect to the length of time would lead to occasional disaster, since each fracture shonld be largely treated upon an independent basis. He failed to see how any text-book on surgery could successfully formulate special rules, except for special cases. Even then he thought the best results would arise if the fracture was given the benefit of the doubt rather than if it was treated according to the stereotyped statements of text-books.

Dr. S. T. Armstrong said that the treatment of a case of fracture, like that of all other cases of snrgery, must be based upon the essential features of the particular case. He did not think that the author of the paper had advocated the nse of an anæsthetic for the purpose of simplifying the making of the diagnosis, but had argued that the resulting relaxation would enable the surgeon to make more certain work of the adjustment of the fragments and the application of the dressings. The removal of a fracture dressing permanently after the fourteenth or twenty-first day would, in the opinion of the speaker, lay the surgeon who allowed it open to an action for damages should any accident ensue as the direct or indirect result of the permission or advice.

Dr. von Dönhoff said that he had intended to convey the idea that he would give an anæsthetic for the purpose of adjusting the fragments and of avoiding the struggles of the patient, and not for the mere purpose of making a diagnosis. He held it to be the business of every surgeon to be able to make a diagnosis from a familiarity with the topographical anatomy of the parts involved unless the injury extended into a joint cavity. Still, he thought that examination and adjustment under anæsthesia would allow of quicker and better work with less injury to the parts than was often possible when no anæsthetic was used. He had seen no mishaps from chloroform. The use of an anæsthetic was nothing as constituting an additional feature of gravity in the case, but rather the contrary. As to the gross topography of a fracture, he thought it good practice to study the tissues themselves, to note the amount of swelling and the propriety of interfering with the same surgically; to notice the signs of hæmorrhage about the fracture, and whether operative interference should be employed for its relief; to determine the nature of the vascular lesion, as to whether there was a large bleeding vessel likely to militate against physiological repair. He did not think it good practice to put a fracture up in a permanent dressing and leave it to chance and a prognosis based on the ontside appearance of the dressing. There was sure to be a subsidence of the swelling long before adequate union of the fragments, and an ugly deformity might result before the limb was seen. He thought that in the case mentioned by Dr. Bryant there could have been no union at all. Perhaps there had been failure to get the fragments opposed, an accident easily avoided if his method was adopted. Too much care and attention could not be given to the matter of ankylosis, so extremely likely to occur in the course of the prolonged confinement of joints and so tedious and difficult to overcome when once developed. Neither he nor the gentlemen who had contributed to the statistical tables mentioned in his paper had witnessed any secondary accidents while practicing the method he had been advocating.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of October 7, 1890.

The President, Dr. Landon C. Gray, in the Chair.

Tuberculous Meningitis.—Dr. W. B. Pritchard presented the brain of a patient who had died from this cause. When first seen by the speaker, the man had been suffering from obstinate insomnia and headache. A few days subsequently the thermometer had shown some elevation of temperature; but this had never exceeded 103° at any time until shortly before death. The mental disturbances had been very marked from the beginning. There had been complete loss of memory, right-sided ptosis, difficulty and finally loss of speech, and the rapid development of symptoms of complete bulbar paralysis. The apparent immediate cause of death had been the involvement of the vagus. There had been decided right hemiparesis. A very offensive purnlent discharge from the nose had been persistent, which had continued until death. The autopsy had revealed over the right parietal bone a cavity of about the size of a silver dime, the necrosis being presumably tuberculous in character. Over the patient's right eye there had been a linear scar with a depressed fracture, but no apparent affection of the brain from this cause. At the base of the brain there was found a thick tenacious material. The medulla, pons, crura, and cranial nerves were involved, and the dura was covered along the convexity of both hemispheres with what were presumed to be masses of tuberculous deposit.

Can we diagnosticate Hyperæmia or Anæmia of the Brain and Cord?—Dr. William A. Hammond, of Washington,

read a paper on this subject. The writer had for many years been familiar with a group of symptoms which, from their ætiology and general characteristics, were indicative of cerebral disturbance; and some twenty-five years ago, after considerable observation and many experiments performed upon living animals and the human subject, he had come to the conclusion that they were the result of an increase of the amount of blood circulating in the vessels of the brain. His conclusions were first published in an article on Insomnia in 1865, various papers appearing on the subject at subsequent intervals; and lastly in a monograph, issued in 1884, entitled *Cerebral Hyperæmia the Result of Overmental Work or Emotional Disturbance*, in which additional facts, the outcome of continued experience, were brought forward in support of the theory advanced. In the writer's opinion, there were certain symptoms which positively indicated the existence of cerebral hyperæmia, and which he had designated as symptoms of the first class. There were others which inferentially led to the same conclusion, especially when they were associated with symptoms of the first class. Those were embraced under the term symptoms of the second class. Others, again, were indicative of derangements of various organs of the body, which, though important as adding to the discomfort of the patient, might be due to many different primary pathological states, and therefore were not included in the present discussion. The symptoms of the first class were: first, wakefulness; second, pain, heat, a feeling of fullness or distention in the head, a sensation of a band encircling it, a dragging and clawing sensation at the vertex, vertigo, and hallucinations, provided, and this point was especially impressed, that those symptoms were increased by any known factor which increased the amount of blood in the brain; and, third, a congested condition of the tympanum and the optic disc, the retina, and the chorioid. The theory which the writer had advanced repeatedly was that natural sleep was due to a comparative anæmic condition of the brain, normal wakefulness to an increase of the amount of blood in the cerebral vessels, and insomnia to an abnormal quantity of intracranial blood. Persistent insomnia was the necessary accompaniment of the pathognomonic symptom of the affection in question. Without wakefulness there was no cerebral hyperæmia; with cerebral hyperæmia there was always wakefulness. Numerous experiments made upon animals had fully demonstrated those facts. It was well known that during the process of digestion there was a diminished amount of blood in the brain, and it was for this reason that persons felt sleepy after a hearty meal. Although those observations and experiments were conclusive enough, further demonstration had been made by means of an instrument devised for the purpose of determining the existence of cerebral hyperæmia. By its means observations were made upon the movements of the brain and the blood pressure within the cranium. It consisted of a brass tube, which was screwed into a round hole made in the skull with a trephine. Both ends of this tube were open, but into the upper was screwed another brass tube, the lower end of which was closed by a piece of very thin sheet India rubber, and the upper end with a brass cap, into which was fastened a glass tube. This minor arrangement contained colored water, and to the glass tube a scale was affixed. This second brass tube was screwed into the first till the thin rubber pressed upon the dura mater and the level of the colored water stood at 0, which was in the middle of the scale. Now, when the animal went to sleep, the liquid fell in the tube, showing that the cerebral pressure had been diminished—an event which could only take place in consequence of a reduction in the quantity of blood circulating in the brain. As soon as the animal awoke the liquid rose at once. The experiments were performed upon dogs and rabbits, and in every instance the pressure was lessened during sleep and increased during wakefulness. The writer thought that nothing could exceed the conclusiveness of experiments of this character. Of the second group of symptoms, hallucination, being the most remarkable, was the only one considered. A number of cases were cited from the recorded experience of the writer and other observers. In most of the cases reported the spectre or apparition had appeared to the persons on retiring to rest or inclining forward, and vanished when the erect posture was assumed. The explanation of such cases was very simple. The recumbent posture facilitated the flow of blood to the brain, and at the same time tended, in a measure, to retard its exit. Hence the appearances were due to the resulting congestion. As soon as the individuals rose in bed or stood erect, the reverse condition existed, the congestion disappeared, and the apparitions went with it. Hallucinations of hearing were not infrequently produced by like causes. A number of cases were related to illustrate this point. The writer did not want to be understood as saying that there was a fixed condition of the fundus of the eye and the tympanum which was associated with cerebral hyperæmia; but that observations should be made from day to day in each case, when it would be found that as the other symptoms of cerebral hyperæmia disappeared, the retina, the chorioid, and the tympanum would lose their congested appearance, so that, when health was restored, the fundus of the eye and the drumhead would be found to be very different from what they were when the disease was at its height. There were certain agents which, by their action, appeared to increase the amount of blood in the brain, and others which apparently diminished it, and which were, hence, important in their diagnostic relations. If to a person suffering from insomnia, pain in the head, vertigo, and hallucinations, should be given one or two hundredths of a drop of nitroglycerin, the trouble would become augmented and unbearable. Like effects followed the use at such a time of quinine, strychnine, and other agents. Among those remedies used to diminish the amount of blood in the brain, the bromides stood pre-eminent. Another diagnostic factor was in the action of ergot. As was well known, this substance possessed the property of constricting the organic muscular fiber. The writer was convinced, from personal investigations, that ergot did contract the cerebral vessels, and hence diminished the quantity of intracranial blood. The writer said in conclusion that when he had a patient suffering from insomnia, pain in the head, vertigo, hallucinations, suffusion of the face, cephalic heat, and other striking symptoms of perhaps less special importance, and when he found these symptoms disappear under the influence of remedies such as the bromides, ergot, ice, and douches of cold water to the nape of the neck, cups in the same locality, nasal bloodletting or spontaneous hæmorrhage, position, and other means calculated to diminish the amount of intracranial blood, he did not see how an escape was possible from the conclusion that the patient was suffering from cerebral hyperæmia.

Dr. M. A. Starr said that while he did not wish to be understood as representing those who opposed Dr. Hammond's views, still his convictions at present were those expressed by Dr. Gray in his paper read recently before the society. (See the *Journal* for May 24th, page 561.) The symptoms which had been explained by the existence, or assumed existence, of cerebral hyperæmia were, many of them, symptoms which could be produced by other causes; such, for example, as wakefulness, which was often noticed in individuals when very much exhausted and in puerperal women who had suffered severe hæmorrhage. He had also certainly observed it in patients who were anæmic. Therefore, to say that wakeful-

ness necessarily indicated a hyperæmic brain was to advance a theory which was hardly tenable. Certainly hyperæmia of the brain might, under certain conditions, be diagnosticated, but it was a very open question whether this could be done when only wakefulness was present. As to the question of drugs, they had been very much surprised to hear it stated by Dr. A. H. Smith and Dr. Peabody, at a meeting of the Practitioners' Society last winter, that those gentlemen had been treating cases of supposed hyperæmia of the brain with nitroglycerin and nitrite of amyl. These drugs, which were supposed to increase the supply of blood to the brain, were being given upon the hypothesis that they dilated the entire arterial system of the body, and the brain would thereby be relieved to a certain extent of blood. The reasoning, at least, appeared sonnd. The speaker thought it impossible to base a diagnosis upon any individual symptom.

Dr. J. Leonard Corning thought this was not scientific reasoning. The truth might probably be more nearly arrived at by careful indnction. If a man came complaining of headache, having a congested face, with a pulse of high tension, whose symptoms could be promptly relieved by pressure upon the carotids or the jngulars, or by bandaging the legs, might snch a patient be assumed to be suffering from congestion or anæmia of the brain? The speaker thought it was congestion. Suppose qninine or alcohol should be given to such a patient, and it was found that the symptoms were aggravated, it would be certainly concluded that the trouble was congestion.

The President said that of course Dr. Hammond spoke with authority; this they were all prepared to admit. The fact that he was able to do so had much to do with the acceptance of his conclusions without criticism. Still, no dictum in relation to a scientific point could be allowed to stand on personal authority alone. The conclusions must bear the force of investigation and be supported by fact. Dr. Hammond must not consider the discussion as having the least personal bearing, but as merely the expression of a general desire to elucidate the problem as far as possible. Dr. Hammond had stated the symptoms of cerebral congestion as being sleeplessness, with a certain feeling of compression or oppression about the head and a flushing of the face.

Dr. Hammond here suggested that he had said these symptoms were increased by the dependent posture or by anything which wonld increase the amount of blood in the brain.

The President accepted the correction, and went on to enumerate the conditions in which these symptoms might be found. For instance, insomnia was common enough in mental diseases and worry, melancholia, overwork, constipation, and many conditions in which there was nothing to show that there existed any hyperæmia of the brain. In the early stages of intracranial syphilis there was a condition somewhat of the nature of hyperæmia. But, then, in Bright's disease, in which there were hyperæmia and congestion, there existed a condition of stupor. If the list of causes of insomnia were gone through, it would be possible to find a certain train of symptoms which would lead to the assumption of existing anæmia in some and hyperæmia in others. Experiments had recently been made on the brains of animals, the report of which differed from those of other recorders; as to the point made that the brain rose or increased in volume during the waking period, it was an open question whether this was not due to cellular action producing an increase of bulk. As to the association of sleeplessness with the recumbent posture, of course the extended observations of the author of the paper were deserving of due consideration; but so also were the more limited observations of the speaker in this respect, and he had not been able to verify the association. The question before them was not as to the existence of cerebral hyperæmia or anæmia, but as to whether it could be clinically diagnosticated. Flushed face might be dependent upon chorea, general paresis, or injury to the brain. It was impossible to say whether the symptom was brought on by hyperæmia alone. The feeling of oppression and sense of fullness in the head was found associated with errors of refraction, insufficiency of the ocular muscles, changes of climate, errors of diet, and so forth. To assume that in all those conditions there was hyperæmia of the brain was assuming a good deal and more than could be proved. It was a point which had not been demonstrated by any pathologist, as to whether there could exist by itself an increased amount of blood in the cellular tissue or other finer structures of the brain without causing disease of the surronnding parts. It was strange that Dr. Hammond, after five months' preparation of the snbject, had cited no autopsies in confirmation of his theory.

Dr. C. L. Dana said that he thought it was now generally agreed that there was such a condition as cerebral hyperæmia and that it could be recognized in its acute forms. Such a state might be produced by drugs, congestive neuroses, trauma, and so forth. The question had been and was, What was the condition at the base of that functional disorder which had gone by the name of cerebral neurasthenia? whether its initial stage was that of hyperæmia, or the hyperæmia was a secondary process. An acute and a chronic hyperæmia of the brain were conditions admitted to exist, but it was preferable to say functional cerebral neuroses or psychoses where the hyperæmia was a secondary process, and that seemed the inevitable conclusion to those who watched these cases. Many patients among the nenrasthenics showed symptoms of congestion of the brain; others of this class did not in any way present the symptoms of the classic type of cerebral hyperæmia, but showed the condition so shaded down that it was necessary to set aside all the symptoms generally described. There was something at the back of the hyperæmia. The hyperæmia of the brain was secondary to some disorder of the vaso-motor nerves or to some functional condition involving the whole nervous system. As to insomnia and cerebral hyperæmia, that question was obsolete. To state that sleep was prodnced by anæmia and wakefulness by the return of the normal amount of blood to the head was, the speaker thought, in the light of modern neurological studies, a theory which could be described as unworthy of further investigation.

Dr. Hammond thought that his points had been unanswered in the argnment. When Dr. Dana said that the neurologists of to-day ignored the theory of the physiological changes during sleep, a theory which the speaker might claim as his own, he thought Dr. Dana in error. He wonld remind them that he had stated that headache presented innumerable causes for its existence, and it was only when he found it with flushed face and vertigo and when it was increased by the dependent position of the head that the diagnosis was certain. Then he knew his patient had hyperæmia of the brain, all the neurologists in the world to the contrary notwithstanding.

The Sensation of Itching.—This was the title of a paper by Dr. E. B. Bronson. He said that it was a somewhat remarkable fact that a manifestation of cutaneous irritability so common as itching, and one with which as a symptom we were so familiar, had been almost entirely neglected as an independent study. Of other anomalies of sensation—such as hyperæsthesia, anæsthesia, and pain—we had tolerably clear and definite ideas. But what were the cause and nature of pruritus? what was this disturbance of sensation? Notwithstanding the fact that the special senses in their present state were so far removed, in respect to the knowledge they yielded to consciousness, from

common sensation, there doubtless had been a period when the distinction did not exist. Their differentiation had been the result of gradual and long-continued processes of evolution. There could be little question that the sensory organs to which the several senses owed their special attributes had all originally developed from simple nerve endings that gave but the vaguest intimations of external objects. In this evolution the impelling force, the directing impulse, had been derived from the two grand principles of life known as the instinct of self-preservation and the instinct of reproduction. To one or the other of those instincts every sensation that arose in the body must be directly or indirectly referred. All sensations, as had been shown, were originally tegumentary. To the common integument must be ascribed the source and potentiality of all sensations. As the result of specialization, most of those sensations had been withdrawn from the exterior. What traces of the special senses thus abstracted still persisted in the skin might be infinitesimal. There still remained to the skin and adjacent mucous orifices a variety of sensations, others more specialized, including a special sense with perceptive faculties, and finally the most important representative of the reproductive instinct, the aphrodisiac sense. The only sense with which the skin was endowed that could be called perceptive and that was worthy of comparison with seeing, hearing, smelling, and tasting was the sense of pselaphia. It included the sense of contact, which was seen in its most primitive form; its most important element was the pressure sense, while the temperature and muscular senses were more or less essential auxiliaries. Common sensation was represented in the integument in its highest positive aspect by the voluptuous sensations, in its lowest negative aspect by pain. Returning to the question, What relation to the sensory organs of the skin and to their sensations did the sensation of itching bear? the author believed that there was sufficient evidence to locate the essential seat of pruritus in the epidermis. Itching was evoked by such irritants as acted upon this tissue much more uniformly than by those that acted on the derma. However provoked, the sensation of itching was always associated with a presentment to consciousness as though a foreign body were in contact with the surface. It was that sensation that experience through many stages of animal life had taught was often followed by a prick or a sting, and the inclination to escape the threatened hurt had grown into an animal instinct. The cause of contact at a minute portion of the sensitive surface was immediately interpreted to mean a miniature attack that must be repelled. If no attack had really been made, but only the threat, then the excitement should disappear without returning the moment the cause producing the sense of contact was withdrawn. But it was this peculiarity of itching that it persisted in spite of such withdrawal, and was only relieved by the act of scratching. It seemed as though the contact, or whatever the change might be that gave rise to the irritation, produced a molecular commotion in the nerves that went on like the jangling of an electric bell, with the continuance of the sensation until such time as the surcharge of nervous energy was released. In pselaphia the nerve force or the molecular vibrations excited by the impact was directly transmuted into some intelligent form of activity, and the accumulation of nerve excitation, the nervous engorgement, did not occur. The circuit was complete with no point of resistance intervening to produce obstruction and commotion. With regard to the effect of scratching in relieving itching, it was analogous to that produced by muscular exertion, as in those animals in which the platysma myoides was more highly developed than in man, as in the horse and bovine genera, a certain relief might be afforded to pruritic sensation through its energetic contractions, and this was not wholly due to expulsion of the insect or whatever else might have caused the sensation. While some of the phases of itching might be associated with pathological changes in the epidermis, others had their source more deeply situated and were referable to the nerve centers. To the latter belonged the form of neurosis of which pruritus was at the same time the symptom and the sole appellation. Still other sources were doubtless to be found associated with apparently normal physiological conditions. While those represented the most obvious sources of itching or provocations for scratching, there was another factor of which hitherto but little account had been taken. Both the English words itch and itching, and the Latin prurio and pruritus, in their secondary significations conveyed the idea of a longing, teasing desire, while pruritus was commonly used by the Latins as a synonym for lasciviousness. By desire, something more was meant than merely the inclination to brush or scratch away a foreign body, of which the sensation was apparently an intimation. It was rather a kind of desire closely akin to a lustful feeling and one that sometimes made scratching veritably a sensual indulgence. When pruritus reached a certain degree of intensity, the subject was not content with that moderate amount of scratching that would ordinarily create a sufficient diversion to give relief, but there was a disposition to attack the itching surface with a vehemence that amounted to a passion. Recognizing this peculiar element of desire in pruritus, the sexual excitement and depraving tendencies that were so commonly associated with pruritus genitalium were most easily explained. But it was not so surprising that voluptuous sensations should attend itching where they had their natural seat; such sensations were, however, not confined to the genitalia. They might be concomitants of itching in almost any situation. By means of a violent excitation induced by severe scratching, provoked by pruritic irritation, a liberation or discharge of nervous energy took place accompanied by pleasurable sensations, together with the relief of the pruritic irritation. A temporary inertia and rest followed and continued until a renewal of the pruritus provoked another resort to the same method of relief. As to why these processes were attended with pleasurable sensations, it sufficed to say it satisfied a law of being. Gratification of appetite was a condition of life, either of the preservation of life or of the reproduction of life. The sexual, the aphrodisiac appetite could only be secondary to the instinct and appetites of self-preservation. From the foregoing considerations the following conclusions were drawn:

1. That there was a sense of contact independent of the sense of pselaphia.

2. That this sense of contact was the sense disturbed in pruritus.

3. That it primarily concerned simple cutaneous nerves or nerve endings situated superficially and probably in the epidermis.

4. That the disturbance in pruritus was of the nature of a dysæsthesia due to accumulated or obstructed nerve excitation with imperfect conduction of the generated force into correlated forms of nervous energy.

5. That scratching relieved itching by directing the excitation into freer channels of sensation—sometimes, especially when severe, substituting for the pruritus either painful or voluptuous sensations.

6. That the voluptuous sensations which might attend pruritus were a manifestation of a generalized aphrodisiac sense, representing a phase of common sensation that had its source in the sense of contact.

Dr. L. D. Bulkley considered Dr. Bronson's paper one of the most scholarly he had ever listened to. He then referred to some studies he had made as to the reflex character of itch-

ing. For instance, if the itching sensation were on the finger of the right hand, irritation or pinching of that finger would cause a reflex sensation of itching in the neighborhood of the scapula of the same side. He had only found one or two instances in which it was transferred to the opposite side.

Dr. Starr asked whether it was ever thought that itching was a symptom of central nervous disease. Patients with locomotor ataxia were said to be frequently troubled with itching around the anus, scrotum, and perinæum. He had never seen a case confirming this.

Dr. B. Sachs had never seen it in organic nervous disease, but in functional disorders, such as crural neuralgia, he had known the itching to be more obtrusive than the pain. It was a frequent condition of profound anæmia, and often observed in hysterical women and in cases of hystero-epilepsy.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN THEORY AND PRACTICE OF MEDICINE.

Meeting of October 21, 1890.

Dr. Francis Delafield in the Chair.

Purpura Hæmorrhagica.—Dr. G. R. Lockwood read a paper with this title. As ordinarily described, purpura hæmorrhagica, or morbus maculosus, was a disease characterized by spontaneous hæmorrhages, not only appearing subcutaneously, as in simple purpura, but also from the mucous membranes, and more rarely into the serous membranes, internal organs, and joints. This disease was first described by Werlhof in 1775, and was known as Werlhof's disease. The patient usually presented prodromal symptoms, which might precede the actual onset several days or weeks—malaise, chilly sensations, loss of appetite, and possibly a slight rise of temperature being the prodromes most commonly seen. In other cases the disease might begin abruptly. When the disease was fairly developed there was purpura, the spots varying greatly in size, usually upon the extremities, though they might be generally distributed. There were hæmorrhages from various mucous membranes. In some cases there was constitutional disturbance. In such cases the disease lasted from two to four weeks and tended to recovery, though relapses were to be expected. In some cases in children the disease manifested itself by purpura, pain and swelling of the joints, and abdominal pain and tenderness, with tenesmus and bloody stools. It was characteristic of the disease for the patient to suffer from a number of these attacks at short intervals. Letzerich, in a recent monograph, had given the result of bacterial examination of the purpuric spots in a case which he had attended. Long bacilli were found capable of growth in gelatin, the pure cultures of which, injected into the abdomen of rabbits, reproduced the original clinical symptoms in all of twelve cases, and in these the same bacilli were found identical with those of the pure cultures injected. The liver in the rabbits was regularly enlarged and the portal capillaries were almost occluded by an extraordinary growth of the bacilli. Letzerich considered the liver to be the breeding place of the bacilli in Werlhof's disease, the liver being to this disease what the spleen was to malarial fever. If he was correct in this view, it helped explain both the scattering of the lesions, a bacterial embolism of the capillaries, and also the tendency of the disease to relapse, as well as the periodicity of the relapses seen in some cases. A number of cases of varying intensities were then alluded to by the author. When these were considered together, one was struck, he said, by their similarity to the class of acute infectious diseases. The absence of assignable cause, the rapidity of the onset, the multiplicity and the scattering of the lesions, the enlargement of the liver and spleen, and the constitutional symptoms out of proportion to the local lesions found, seemed to prove by analogy the assertion that we were here dealing with an acute infection. Purpura hæmorrhagica was but one of a group of diseases having two essential features in common—tendency to spontaneous hæmorrhages and constitutional symptoms. The family resemblance of those diseases and their relationship to the other hæmorrhagic disorders of this group were then dealt with. In summing up, the points to which discussion was invited were as follows:

(1) Werlhof's disease was probably infectious in origin, the exact agent of infection not having been absolutely proved, though it might be the bacillus described by Letzerich.

(2) There were acute cases of this infection in which death resulted from acute anæmia, from internal hæmorrhage, or from sepsis.

(3) Purpura simplex and purpura rheumatica were probably types of different grades of the same infection, and this infection might be the same as that of Werlhof's disease.

(4) Scurvy, if proved an infectious disease, might be really Werlhof's disease modified by the surroundings and poor condition of the patient, and also by the possibility of the infection being more chronic.

(5) Drug purpura, anæmic and cachectic purpuras, purpuras in exanthemata and other infectious diseases, purpuras in the newly born, in endocarditis and multiple sarcomata, as well as those of neural origin, might present all grades of severity; one could in each determine a cause, though it was not possible to know exactly how the symptoms were produced by this cause, whether by blood changes or vessel changes or from nervous causes, but these purpuras were symptomatic and not essential, and should not be classed with purpura hæmorrhagica or Werlhof's disease until there was more definite information on the subject.

Dr. W. P. Northrup related the histories of two cases of scorbutus occurring in young children. Both children were being nursed by the mother and were in good general condition; there was no evidence of rhachitis about either child. There were hæmorrhages from the various mucous membranes, and also subperiosteal hæmorrhages. From a study of the subject, the speaker was convinced that scurvy was not a disease of malnutrition, but that there was an absence from the blood of some important essential element, which changed condition allowed it to permeate the walls of the blood-vessels.

Dr. L. E. Holt mentioned a case which had occurred in an infant six months old. The child had been nursed by the mother and was well nourished. In this case the first symptom noticed was the development of a subboccipital tumor, spots appearing on the body at a later date. The temperature had at no time risen above 101° to 102° F., and just before death internal hæmorrhages had taken place. The whole course of the disease was such as to lead to the belief that there was acute infection of some sort present. The speaker thought that these cases belonged to the acute infections class.

Dr. Jackson described an interesting case which had occurred in his practice. The patient, aged thirty-four, a baker by occupation, was enjoying perfect health when hæmorrhage from the bowels came on without any known cause. This continued at intervals for about two weeks, when the patient died from exhaustion. The temperature had gradually risen before death to 102° F. On autopsy, careful examination revealed absolutely nothing which could point to a cause or effect of the hæmorrhage.

Dr. Gibbs's case was that of a young, healthy man, aged twenty-six. The patient was of fine physique, and had never been sick in his life, being always accustomed to outdoor pursuits. After taking a long walk on the sea-shore, he had felt

an uncomfortable sensation in his lower limbs, which had amounted almost to pain. On looking at the legs, hæmorrhagic spots were discovered reaching to the knee. In four or five days the pain had become very severe and the spots had extended up over the thighs, covering in a short time the entire body. Twelve hours before death the wrist joints and phalangeal articulations were attacked, these being the only joints involved. The entire skin was covered with the spots, and all the mucous membranes were involved. In the mouth there could be seen black sloughs, which extended as far as a view was possible into the pharynx and nares. There was considerable vomiting of altered blood. The whole course of the disease had terminated in two weeks. Consciousness continued until death, which was caused by exhaustion and collapse. Careful inquiry into the history of this case could elicit nothing which pointed to a cause. But the speaker had been struck by the close resemblance of its symptoms to those of an acute infectious disease.

Dr. Wood gave the history of a case occurring in a pregnant woman. About the fifth month there appeared upon the abdomen some spots which excited considerable anxiety. The previous health of the patient had been good, but there were several cases of malarial infection in the same house, and the unusual condition was attributed to that cause when the patient was first seen. However, under the speaker's observation the purpura had disappeared, and the woman was delivered at full term, the mother and child had both done well and were healthy at the present time.

Dr. Quinn related the history of the case of a young man, aged twenty-one years, in perfect health, who was taken suddenly with hæmorrhage from the bowels. This had recurred periodically every eight days. There was no high temperature during the course of the disease, but just before death the temperature had risen to 101° or 102° F., the patient dying from exhaustion. In this case the most careful inquiry failed to find any assignable cause for the disease.

Dr. A. H. Buckmaster accorded entirely with the views of the author of the paper and with the gentlemen who had preceded him. He related the history of a case of hæmorrhagic small-pox. From his study of hæmorrhagic disorders he was led to believe that purpura could be produced by other causes than infection. He then spoke of the treatment of such cases by ergot, and the good results to be obtained by this drug. He did not think that cases of scorbutus were due to infection, but to blood changes brought about by some faulty supply of necessary material to it.

Dr. A. Jacobi said that sudden hæmorrhage and death must, in almost all cases, be caused by poisons. He had seen this occur from poisoning by phosphorus and chlorate of potassium. These drugs causing a change in the hæmoglobin of the blood, inquiry ought to be made in every case in regard to the possibility of poison being a factor of its cause. He thought that Werlhof's disease was likely to appear more than once in the same patient. While Letzerich had made repeated experiments and had been able to isolate a bacillus and also to reproduce the disease, this was by no means conclusive and had not been confirmed by other observers. The disease might be due to an impoverished condition of the blood-vessels, to infection, or to a bacillus, but, as this had not been proved, it was just as well to accept any broad statements as to the cause with some degree of reserve. The speaker believed in the kinship of all the forms of the disease as grouped by the author of the paper.

Dr. Northrup asked if he might state that recent investigations by two Italian observers, Dr. Giovanni and Dr. Tizzoni, had confirmed the discovery of Letzerich, and that their entire demonstrations were practically identical.

The Chairman thought that the whole trouble lay in the fact of our extreme ignorance on the subject, and that no one knew why the blood-vessels at one time retained their contents and at another time did not. It was a question whether the hæmorrhage was due to a rupture of the blood-vessels or to transudation. The speaker thought that the subject was one that required continued study, and that Dr. Lockwood in thus grouping the cases had done all that could be done at the present time.

Dr. Lockwood, in reply to Dr. Northrup as to the confirmation of Letzerich by other observers, said he had no knowledge of that having taken place. Letzerich explained that the liver was the breeding place of the bacilli, and that from there the system received or was surcharged with the germs, their life ending in the system.

AMERICAN GYNÆCOLOGICAL SOCIETY.

Fifteenth Annual Meeting, held in Buffalo, September 16, 17, and 18, 1890.

The President, Dr. John P. Reynolds, of Boston, in the Chair.

(*Concluded from page 502.*)

The Comparative Value of the Biniodide and the Bichloride of Mercury as Surgical Antiseptics.—Dr. Charles Jewett, of Brooklyn, read a paper on this subject, in which he stated that biniodide of mercury was less toxic than the bichloride; if used in proper concentration, it was as potent as a germicide; it was a more stable chemical compound; it was more agreeable to the operator. Experiments made at the Hoagland Laboratory gave the following conclusions:

1. In equal concentration, the biniodide was slightly inferior to the bichloride in germicidal power. 2. For equal potency as a sterilizing agent, the biniodide should be used in greater concentration than the bichloride—say 1 to 1,800. 3. The difference in the efficacy of a 1-to-2,000 solution of bichloride and a 1-to-1,000 solution was insignificant. 4. The activity of a 1-to-2,000 solution of biniodide was materially greater than that of a 1-to-4,000 solution. Alcohol should be used before the sterilizing solution for its hygroscopic action.

Tait's Flap-splitting Operation.—Dr. Horace T. Hanks, of New York, read a report of his recent experiences in the use of the flap-splitting method of Tait. He presented the histories of five successive cases in which the results were perfect. He said that Tait's operation, which had been frequently described, was the best, the most simple, and the most easily performed. He insisted that one prominent and necessary detail to secure perfect results was keeping the bowels loose from the second to the tenth day after the operation.

Dr. E. C. Dudley, of Chicago, had performed Tait's operation formerly, and had always succeeded in getting union, but had since discarded it, as it did not sufficiently bring together the torn parts—not being a restorative operation. He believed the condition of a lacerated perinæum through the sphincter indicated simply an operation which would restore the parts to the condition they were in before the tear occurred. The first step was to bring together the lowest caruncule myrtiformes with two tenacula, when the direction of the original rent and cicatrix could be made out. The perineal body was then restored by the method suggested by Emmet. In thirty-six to forty-eight hours a cathartic was given, and before the movement an enema of warm water, and the bowels were kept open until union was complete.

Laparotomy for Intrapelvic Pain.—Dr. Thomas A. Ashby, of Baltimore, in a paper with this title, said that intrapelvic pain was associated with many intrapelvic conditions,

but was not always in proportionate severity to the disease. Besides the pain which pointed to structural lesions, there were chronic ovarian neuralgias, which, before the menopause, resisted treatment. It was for this class of cases in particular that laparotomy was advised. Operation was also essential in cases in which a diagnosis could not be clearly made, and pain was severe.

Dr. Kelly, of Baltimore, eliminating personalities, would strongly condemn the practice of performing laparotomy for pain, notwithstanding that in some cases it afforded the most typical relief. He believed oophoralgia was rarely heard of, the condition which characterized it generally arising from some other disease of the organ. The admission of laparotomy for this condition would lead to the practice of seven or eight years ago, when laparotomy was performed for every known disease. These ovarian troubles could always be diagnosticated by bimanual palpation or combined rectal and vaginal examination in anæsthesia. The uterus could be brought down to the vaginal outlet with the tenaculum, when the ovaries could be easily reached. If extensive adhesions existed, the uterus might be brought down into retroposition, and rectal examination would disclose the ovary, a little, characteristic, almond-shaped body. If it was not found in this way, the utero-ovarian ligament might be looked for running out to the right or left of the uterus. When this was found, by pushing it up it was easy to ascertain whether the ovary was adherent or not. Radical measures should not be resorted to until all other forms of treatment were exhausted.

Dr. A. Palmer Dudley, of New York, was in favor of laparotomy for the relief of the conditions which produced pain, after all other methods of treatment had failed. He believed it was impossible to diagnosticate certain diseased conditions of the ovary by bimanual touch, and that laparotomy was the only proper procedure in such cases. Vascular disturbance was the foundation of the majority of pelvic diseases in women. There were no valves to the ovarian veins from the ovary up to the renal vein, and they were pressed upon by the sigmoid flexure of the colon and the transverse circulation of the kidney, sometimes causing what might be considered a varicocele.

Dr. Polk, of New York, understood Dr. Ashby to refer simply to an exploratory incision in these cases, and in that sense he thought he was entirely right. He did not believe it was possible in all cases to make out the diseased conditions of the ovaries by rectal or vaginal touch.

Dr. Henry T. Byford, of Chicago, believed that laparotomy should not be resorted to for the cure of pain that could be cured otherwise.

Dr. Matthew D. Mann, of Buffalo, did not believe that a diagnosis was possible in all cases before the abdomen was opened. He believed in the exploratory incision as a means of diagnosis. He doubted whether minute disease of the ovary could be recognized by a simple incision of the organ, and was inclined to believe that the whole organ ought to be removed. He was confident that in a number of cases the ovaries and tubes had been removed when the trouble was entirely in the ureters.

Officers for the Ensuing Year.—The following were elected: President, Dr. A. Reeves Jackson, of Chicago; Vice-Presidents, Dr. Joseph Taber Johnson, of Washington, and Dr. William H. Baker, of Boston; Secretary, Dr. Henry C. Coe, of New York; Treasurer, Dr. M. D. Mann, of Buffalo; Members of the Council, Dr. H. P. C. Wilson, of Baltimore; Dr. W. H. Polk, of New York; Dr. E. C. Dudley, of Chicago; and Dr. F. H. Davenport, of Boston.

The society adjourned, to meet in Washington, the third Tuesday in September, 1891, to take part in the proceedings of the Congress of American Physicians and Surgeons.

Book Notices.

The Throat and Nose and their Diseases. With One Hundred and Twenty Illustrations in Color, and Two Hundred and Thirty-five Engravings, designed and executed by the Author. By Lennox Browne, F. R. C. S. E., Senior Surgeon to the Central London Throat and Ear Hospital, etc. Third Edition, revised and enlarged. Philadelphia: Lea Brothers & Co., 1890. Pp. xxii–716. [Price, $6.50.]

Certainly a foreign medical work is worthy of appreciative consideration that so fairly says: "From no quarter have we derived, in these latter days, so many original observations and suggestions of real practical value as from the members of the American Laryngological Association." But, aside from this pleasant compliment, the rich experience of the twelve years that have passed since the first edition of this work appeared has been incorporated in this edition, making the book one of the most valuable works on diseases of the throat in the English language.

Materially, the volume has been expanded to double its original size, the author's beautiful plates have been added to, and the other illustrations have been tripled; by these latter means the practical teaching value of the work has been increased, familiarizing the reader with the appearance of the various pathological conditions that may be found. It is regrettable that the American publishers have not arranged the plates as the author intended, so that they could be opened out "beside the book during perusal of the text descriptive of the disease pictorially illustrated."

The author's former uncertainty regarding the value of intubation of the larynx has been dissipated, and he finds the tubes very serviceable. The chapters on the nose and nasopharynx, while brief, are sufficiently comprehensive.

The work is still worthy of the commendation that it first received.

A Treatise on Diseases of the Nose and its Accessory Cavities. By Greville Macdonald, M. D. (Lond.), Physician to the Hospital for Diseases of the Throat. London and New York: Macmillan & Co., 1890. Pp. xvi–362. [Price, $3.]

The author has made extensive studies and experiments on the physics and pathology of the nose, quite a full chapter being devoted to the elucidation of his theories on this subject. The chapter on nasal reflexes and hay fever is a historical review of what has been said and written on this much-discussed question, the author defining the disease as that of paroxysmal sneezing. He believes that a name for a disease should always keep clear of a theory, and that, as a designation, a constant symptom is preferable to a varying cause. The remainder of the work is made up of chapters on the usual subdivisions of diseases peculiar to the nasal cavities. The book shows the author's ability to make sound deductions from a ripe experience, and proves that he is not at all afraid of saying what he thinks. The work is fairly illustrated.

BOOKS AND PAMPHLETS RECEIVED.

Diseases of the Eye. By Edward Nettleship, F. R. C. S., Ophthalmic Surgeon to St. Thomas's Hospital, etc. Fourth American from the Fifth English Edition. With a Chapter on Examination for Color-perception. By William Thomson, M. D., Professor of Ophthalmology in the Jefferson Medical College of Philadelphia. Philadelphia: Lea Brothers & Co., 1890. Pp. xx–25 to 508. [Price, $2.]

A Practical Treatise on Impotence, Sterility, and Allied Diseases of the Male Sexual Organs. By Samuel W. Gross, A. M., M. D., LL. D., Professor of the Principles of Surgery and Clinical Surgery in the Jef-

ferson Medical College of Philadelphia, etc. Fourth Edition, revised by F. R. Sturgis, M. D. Philadelphia: Lea Brothers & Co., 1890. Pp. vii–16 to 173. [Price, $1.50.]

Text-book of Materia Medica for Nurses. Compiled by Lavinia L. Dock, Graduate of Bellevue Training School for Nurses, etc. New York: G. P. Putnam's Sons, 1890. Pp. 201.

A Case of Brain Tumor (Angeioma Cavernosum) causing Spastic Paralysis and Attacks of Tonic Spasms; Operation. By L. Bremer, M. D., and N. B. Carson, M. D., of St. Louis, Mo. [Reprinted from the *American Journal of the Medical Sciences.*]

A Study of the Anæsthesias of Hysteria. By Charles L. Dana, M. D. [Reprinted from the *American Journal of the Medical Sciences.*]

Lateral Deviation of the Spine as a Diagnostic Symptom of Pott's Disease. By Robert W. Lovett, M. D., Boston. [Reprinted from the *Boston Medical and Surgical Journal.*]

The Production of Immunity with the Chemical Substances formed during the Growth of the Bacillus of Hog Cholera. By E. A. v. Schweinitz, Ph. D., Washington, D. C. [Reprinted from the *Medical News.*]

Three Types of Cerebral Syphilis producing Mental Disease. By C. M. Hay, M. D., Morris Plains, N. J. [Reprinted from the *Medical News.*]

Suppurating Endothelioma; Myofibroma in a Condition of Necrobiosis; Remarks on the Treatment of the Pedicle, etc. By Mary A. Dixon Jones, M. D. [Reprinted from the *Medical Record.*]

The Pendent Limb in the Treatment of Joint Diseases of the Lower Extremity. By A. B. Judson, M. D., New York. [Reprinted from the *Transactions of the Medical Society of the State of New York.*]

Remarks upon Empyema. By Mary Putnam Jacobi, M. D., of New York. [Reprinted from the *Medical News.*]

The Treatment for the Radical Cure of Polypi of the Nose. By E. Harrison Griffin, M. D. [Reprinted from the *Medical Record.*]

Lymphoid Hypertrophy in the Pharyngeal Vault. By Jonathan Wright, M. D., of Brooklyn. [Reprinted from the *Journal of the American Medical Association.*]

Prognosis in Pulmonary Tuberculosis, based upon an Analysis of Five Hundred and Fifteen Cases. By Karl von Ruck, B. S., M. D. [Reprinted from the *Medical News.*]

Medical Aspects of Mental Discipline. Semi-Centennial Introductory Address of the Medical Department of the University of the City of New York. By W. H. Thomson, M. D., LL. D.

The Cæsarean Operation, with the Report of a Case. By A. Palmer Dudley, M. D. [Reprinted from the *American Journal of Obstetrics and Diseases of Women and Children.*]

I. The Prevention of the Short Leg of Hip Disease. II. The After-treatment of Hip Disease. By A. B. Judson, M. D., New York. [Reprinted from the *Transactions of the American Orthopædic Association.*]

A Case of Obscure Disease of the Bladder treated by Suprapubic Cystotomy and Prolonged Drainage. By L. Bolton Bangs, M. D. [Reprinted from the *Journal of Cutaneous and Genito-urinary Diseases.*]

Is there a Fundamental Difference between the Contraction of the Heart and Ordinary Striated Muscle? By Thomas J. Mays, M. D., Philadelphia. [Reprinted from the *Transactions of the College of Physicians of Philadelphia.*]

Miscellany.

The International Congress of Hygiene and Demography.—Dr. John S. Billings, of the international permanent committee, has issued the following circular, dated October 27, 1890: I am requested by the honorary secretaries of the committee of organization of the Seventh International Congress of Hygiene and Demography to call attention to the fact that this congress will be held in London during the week beginning August 10, 1891. The governments of all countries and municipalities and all public-health authorities, universities, colleges, and societies occupied in the study of the sciences more or less immediately connected with hygiene, are invited to co-operate and appoint delegates to represent them at the congress. The Prince of Wales will preside. A committee of organization has been formed, of which Sir Douglas Galton is chairman and Professor W. A. Corfield and Mr. Shirley F. Murphy are honorary secretaries. An exhibition of articles of hygienic interest will be held in connection with the congress. The last of these congresses was held in Vienna in 1887, and was attended by over two thousand persons, and it is expected that the London meeting will be one of great magnitude and importance.

Phenacetin in Typhoid Fever.—"Phenacetin has been used with great success by Dr. Sommer in the treatment of typhoid fever, thus confirming the favorable views of its action which have been expressed by Masius and others. The dose employed for adults was four grains, which was repeated from two to four times during the twenty-four hours. Children were given only half this dose. No less than sixty cases were treated in this way with but one fatal case, after which it is noted that the patient was not subjected to phenacetin treatment until three weeks from the commencement of the attack. In no case were there any serious complications."—*British and Colonial Druggist.*

To Contributors and Correspondents.—*The attention of all who purpose favoring us with communications is respectfully called to the following:*

Authors of articles intended for publication under the head of "original contributions" are respectfully informed that, in accepting such articles, we always do so with the understanding that the following conditions are to be observed: (1) when a manuscript is sent to this journal, a similar manuscript or any abstract thereof must not be or have been sent to any other periodical, unless we are specially notified of the fact at the time the article is sent to us; (2) accepted articles are subject to the customary rules of editorial revision, and will be published as promptly as our other engagements will admit of—we can not engage to publish an article in any specified issue; (3) any conditions which an author wishes complied with must be distinctly stated in a communication accompanying the manuscript, and no new conditions can be considered after the manuscript has been put into the type-setters' hands. We are often constrained to decline articles which, although they may be creditable to their authors, are not suitable for publication in this journal, either because they are too long, or are loaded with tabular matter or prolix histories of cases, or deal with subjects of little interest to the medical profession at large. We can not enter into any correspondence concerning our reasons for declining an article.

All letters, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication. No attention will be paid to anonymous communications. Hereafter, correspondents asking for information that we are capable of giving, and that can properly be given in this journal, will be answered by number, a private communication being previously sent to each correspondent informing him under what number the answer to his note is to be looked for. All communications not intended for publication under the author's name are treated as strictly confidential. We can not give advice to laymen as to particular cases or recommend individual practitioners.

Secretaries of medical societies will confer a favor by keeping us informed of the dates of their societies' regular meetings. Brief notifications of matters that are expected to come up at particular meetings will be inserted when they are received in time.

Newspapers and other publications containing matter which the person sending them desires to bring to our notice should be marked. Members of the profession who send us information of matters of interest to our readers will be considered as doing them and us a favor, and, if the space at our command admits of it, we shall take pleasure in inserting the substance of such communications.

All communications intended for the editor should be addressed to him in care of the publishers.

All communications relating to the business of the journal should be addressed to the publishers.

Original Communications.

SOME REMARKS ON MY HYPOTHESIS OF THE SELF-REGULATION OF RESPIRATION, AND DR. COWL'S DISCUSSION OF IT.

BY S. J. MELTZER, M. D.

IN No. 614 of this Journal, for September 6, 1890, Dr. W. Y. Cowl published an article entitled The Factors of the Respiratory Rhythm and the Regulation of Respiration. In this paper the author criticises adversely my theory of the self-regulation of respiration, upon which criticism I wish to make the following remarks:

In my article * on Self-regulation of Respiration I mentioned the experience I had had while stimulating the vagi with strong electrical currents. During the stimulation the respiration was arrested in the expiratory phase, the inspiratory muscles being relaxed; but after interrupting the current, the arrest changed into an inspiratory phase, a tetanic contraction of the diaphragm. H. Head † reports a similar experience which he had had with prolonged insufflation of the lungs; after cessation of the insufflation, the expiratory standstill changes into an inspiratory tetanus. This phenomenon is termed by Head "negative after-effect." Dr. Cowl asks for evidence to show that this inspiratory after-effect is not dyspnœa from non-aeration of the blood coursing through the respiratory center during the preceding expiratory standstill. This is the evidence I am able to furnish:

1. The intensity and duration of the inspiratory tetanus are proportionally increased with the intensity of the stimulation, and not with its duration, or with that of the expiratory standstill. This shows clearly that the inspiratory tetanus is a primary effect of the stimulation, and not a secondary result from dyspnœa.

2. Dyspnœa from the arrest of breathing in the expiratory phase never effects an inspiratory standstill. If an expiratory standstill is brought about by the stimulation of the superior laryngeal nerve, no inspiratory tetanus is ever observed to follow such a standstill. Furthermore, an expiratory standstill can be effected in some rabbits by stimulating the vagus trunk itself with moderate electrical currents; but here the expiratory effect rather outlasts the stimulation, with no inspiratory after-effect, no matter how long the standstill has lasted.

Dr. Cowl further objects to the inference I am supposed to have drawn from my experiments on the trunk of the nerve, that the lungs themselves are likewise provided with inspiratory nerve fibers, and that these fibers exercise their function in ordinary breathing. On this point Dr. Cowl is mistaken: I did not draw any such conclusion from my experiments. The logical connection between my experiments and my hypothesis is as follows:

My experiments put me in a position to confirm the hypothesis that the vagus trunk contains two kinds of respiratory afferent nerves, which are antagonistic to each other in a manner resembling that of the antagonistic nerves of the heart-beat—*i. e.*, that it contains one kind of nerves which inhibit the inspiration, and another kind which incite and augment it. I could further demonstrate the parallelism between these nerve fibers and the cardiac nerves in some particulars. For instance, the stimulation of the inhibitors of inspiration has only a short after-effect, as is the case with the inhibitory nerves of the heart, while the inspiratory nerves show a long after-effect, similar to the known long after-effect of the nervus accelerans cordis. Further, when both cardiac nerves, vagus and accelerator, are stimulated at the same time, we see during the stimulation the inhibitory effects alone influencing the heart-beat, and this is the case also with the respiratory nerves; strong stimulation of the vagus trunk produces constantly merely inhibition of inspiration — expiratory standstill. Now, if, after cessation of the simultaneous stimulation of the cardiac nerves, the long after-effect of the accelerating nerve appears fully developed, we should expect that a similar phenomenon might occur after the simultaneous stimulation of the respiratory nerves. In fact, after interrupting the strong current, I have observed that the expiratory standstill soon changed to an inspiratory tetanus; and what could this mean but that the expected phenomenon had occurred—*i. e.*, that the inspiratory nerves had been likewise stimulated, that their impulses had been concealed but not destroyed, and that, therefore, after the short expiratory after-effect died out, the long inspiratory after-effect appeared unrestrained and produced the inspiratory tetanus? Thus, as I believe, I gave a satisfactory explanation of the phenomenon of the negative after-effect in my experiments on the vagus trunk; but with this the direct conclusion from my experiments ends. As regards Head's "negative after-effect" after long insufflation of the lungs, I have, of course, applied to it the same explanation which I have given of the similar phenomenon in my experiments. The question: Are the lungs provided with both kinds of nerves as they are found in the vagus trunk? I did not discuss at all. On this point I simply took the same view which Head himself holds, and which is shared by such eminent physiologists as Hering and many others.*

What I added is this: If the lungs are provided with two sets of nerves as they are found in the vagus trunk, which I have no reason to deny, then the same relations ought to prevail between the nerves of the lungs that are found in the vagus trunk, and consequently the negative after-effect following insufflation of the lungs may have the same meaning as that given to the similar phenomenon in

* The *New York Medical Journal* for January 18, 1890.

† Head, On the Regulation of Respiration, *Journal of Physiology*, vol. x, 1889.

* I may quote here an acknowledged authority, Foster, who says, in the latest (5th) edition of his standard text-book, p. 595: "And, assuming on the strength of analogy the existence in the vagus of two sets of fibers, we may say that expansion stimulates the endings of the fibers which inhibit inspiration and concurrently tend to augment expiration, while collapse stimulates the fibers which inhibit expiration and augment inspiration."

the experiments with the trunk. I hold the same position in my hypothesis. I accepted the premises as given by Hering and Breuer, that the lungs are provided with two kinds of nerves, both of which are taking part in the reflex mechanism of the respiration; but, while Hering and Breuer assume that nerves of one kind are stimulated by expansion, and those of the other by the collapse of the lungs, I am of opinion that it is far more rational to assume that both kinds of nerves are always stimulated simultaneously by the same stimulus—the expansion of the lungs—and that the sequence of expiration and inspiration is due to the peculiar mutual relations of the antagonistic nerves (relations which are known to exist in the antagonistic system of the cardiac nerves and which have been found to exist among the antagonistic respiratory nerve fibers of the vagus trunk). In other words, when both kinds of nerves are stimulated simultaneously, the inhibitory effect prevails during the stimulation, but after its cessation the long inspiratory after-effect comes into play.

It is obvious that whoever undertakes to criticise my theory of self-regulation, whether adversely or favorably, is bound to discuss my share in it—*i. e.*, the tenableness of the application of the relations existing between the cardiac nerves to the antagonism of the respiratory nerves. I am sorry that Dr. Cowl has not even touched this point, and yet he says sharply that my new theory of respiratory rhythm deserves further attention, "chiefly because of a disregard therein of a mass of facts that show a central origin for inspiration." As I have to share this reproach with quite a number of physiological writers, it will be easier to bear it. There are some very prominent physiologists who consider it a disregard of facts to maintain that the inhibition of the inspiration is not of a central origin, still on this point I have the pleasure to be on the same side with my critic, who declares himself to be in favor of Gad's theory of respiration. But let us see the "mass of facts" which, according to Dr. Cowl, I (with many others) have disregarded. Two points are enumerated against my theory in Dr. Cowl's paper—the relation of the blood to respiration, and Gad's experiment upon which his theory of respiration is based. Concerning the first point, Dr. Cowl cites a number of authors who have experimentally demonstrated the high sensitiveness of the respiratory center to changes of the constituents of the blood. While I admit the perfect correctness of these facts, I do not see how they could affect my theory. Does Dr. Cowl know of any experiment which shows that the blood, and that alone, is the exciting cause of respiration? On the contrary, there are authors who, while not denying the influence of the blood on respiration, do not consider the blood a necessary factor for the continuance of respiration. A. W. Volkmann* observed the continuance of respiration in a kitten forty minutes after excluding the circulation, and M. Marckwald† puts it up as a thesis (the 17th) that the normal excitation of the respiratory center is independent of the incentives of the blood. As to myself, I am not a party to either side in this question, at least so far as my hypothesis is concerned, the necessary premise to my theory being only the generally admitted assumption that the afferent nerves coming from the lungs normally affect the respiration; and I attempted to establish a hypothesis on the mode of their peripheral stimulations, leaving it an open question whether there were indeed any other causes for the respiration besides the reflex acts. But, aside from my hypothesis, I may say this: In all the discussions on the subject in question I miss the distinction between the significance of the blood as a *cause* and only as a favorable *condition* of respiration—a distinction which is sharply made in the relation of the blood to the heart-beat. There was a time when some physiologists—Haller, for instance—entertained the opinion that the venous blood was the cause of the rhythmic motion of the heart, and although in our days the importance of the blood and its constituents for the heart-beat has been studied and demonstrated (by C. Ludwig, H. Kroneeker, and their pupils), at all events more convincingly than in the experiments on the respiration, still at present the opinion is generally accepted that the blood is significant in the contraction of the heart only as an important condition and not as a cause. I do not mean to say that this view should be adopted also in the doctrine of the respiratory mechanism, in which I admit the possibility that the blood, and more especially its carbonic-acid gas, may be one of the causes of the respiratory movements, but I wish to point out that such an assumption should not be made without good proof, the more so because the blood is of importance to the integrity and function of every organ in the body. This fact seems to demonstrate the value of the blood as a general nutritive rather than as a common stimulus for manifold different functions.

Concerning the experiments of Gad, Dr. Cowl says that they involve facts which are acknowledged to show the pulmonic incitation of inspiration. Gad observed that after dividing the vagi without stimulating them (Gad's freezing method) the inspirations become more predominant. This certainly shows that an inhibitory tonus is removed by cutting the vagi. Gad goes still further. He concludes that the vagi contain only inhibitory nerves, and that inspiration is of central origin exclusively. But this part of Gad's conclusions consists of mere admissible assumptions, not necessarily inferences following from his experiments. I could even use the experiment cited as a proof of my theory thus: On stimulating the inspiratory and inhibitory nerves simultaneously, the inhibitory effect prevails; consequently if there is any tonus from the nerves of the lungs it must be of an inhibitory nature; therefore we see a certain inhibitory influence disappearing after dividing the vagi. My explanation of the said experiment finds a perfect analogy in the cardiac nerves of the frog. According to some authors,* the frequency of the heart-beat is increased after division of the vagi. Should we with Gad conclude that

* A. W. Volkmann, Ueber die Bewegung des Athmens. Müller's *Archiv*, 1841.

† Max Marckwald, Die Athembewegung und deren Innervation beim Kaninchen. *Zeitschrift für Biologie*, 1886, pp. 1–120.

* Funke, Bidder, Rosenthal, and others. See Hermann's *Handbuch d. Physiol.*, Bd. iv, 1. Theil, p. 378.

the vagi contain only inhibitory nerves? We know now* that the vagi of the frog contain also augmenting nerve fibers. Every one explains the said increase by the well-established fact that the inhibitory tonus is the predominating one, just as I would explain the increase of the inspiration after dividing the vagi. But even leaving aside my explanation, why must it follow that the inspiration is of a central origin? We could assume, for instance, that the inspirations and expirations were generated in the respiratory center only by reflex acts from the lungs and from all other parts of the body; but while in the reflexes from the lungs the impulses for expiration are at least not overshadowed by the inspiratory impulses, the latter are predominating in the reflexes from the other parts of the body, or at least in some of them; therefore the predominance of the inspiration after cutting the vagi. I do not mean to defend this theory as my own; I merely wish to demonstrate that Gad's experiments admit of many other explanations than the one given by him; and Dr. Cowl certainly goes too far in considering the experiment in question as a fact against the assumption that the lungs are provided with inspiratory nerves. On the other hand, if we have no sure proof that inspiratory fibers are absent in the lungs, we may assume, with some degree of probability, that such nerves exist there in view of the positive fact that inspiratory nerve fibers are contained in the trunk of the vagus. For what other purpose could these inspiratory nerves be contained in the trunk? As to the expiratory nerves, we might believe that they were for the act of vomiting; but of what use could the inspiratory nerves be if not to supply the lungs?

The main objection to an exclusive reflex theory of respiration is that it ignores the fact that respiration continues after the division of the vagi. This objection has not yet been seriously discussed even by adherents of this theory. Though my own position is not affected by this objection, since my hypothesis does not necessarily exclude other factors for the regulation of respiration, I should like to introduce here briefly some points bearing upon the discussion of the above-mentioned objection. As I pointed out before, there are, besides the reflex from the lungs, many others from nearly all parts of the body, which exert an inspiratory as well as an expiratory influence on the respiratory center. No one denies that fact. Consequently, a vast source of respiratory impulses remains even after excluding the reflexes from the lungs. But while this latter reflex furnishes, in the expansion and collapse of the lungs, an explanatory factor for the alternation of inspiration and expiration, we lack a similar factor in the other respiratory reflexes from which we may expect that the impulses for inspiration and expiration are generated simultaneously. The question, therefore, is not as to where the impulses for respiration arise after the division of the vagi, but as to *what is the source of the alternation* of the respiratory movements? To this we could perhaps answer that the remainder of the reflexes might also possess certain qualitative differences between the inspiratory and expiratory afferent nerves, which could be construed in some way or other as explanatory factors for the continuance of the alternate breathing after dividing the vagi. For instance, smaller degrees of stimulation excite the inspiratory and stronger degrees the expiratory nerves (Langendorff*); or the inspiratory nerves become exhausted earlier than the expiratory nerves (Burkart†); and there are many other ways which still remain to be studied.

But I do not intend to follow out these vague speculations any further. I rather wish to bring forward another reflection which, it seems to me, deserves serious consideration. I mean the introduction into our discussion of the factors of *repetition* and *inheritance*. Suppose the respiratory center were not automatic and received impulses to its working by reflex channels from the whole body, especially from the lungs. The impulses coming from all parts of the body are uninterruptedly simultaneous for inspiration and expiration; but the reflexes from the lungs, by virtue of the steady sequence of the expansion and collapse of this organ, are not simultaneous, but alternately inspiratory and expiratory. May we not expect that such a center, after being life-long influenced by steadily acting reflexes to a prompt alternate working, will acquire, first, a high degree of sensitiveness so as to respond promptly and specifically to the smallest stimuli from whatever quarter they may come; second, a tendency to respond alternately with inspirations and expirations, even on simultaneously received impulses? (This would be the case still more if there were any qualitative differences between the two kinds of afferent nerves tending to their alternate working.) We may expect, furthermore, that such acquired qualities of the respiratory center would be transmitted to the descendants, and that in the course of many generations, by the prompt repetition during the whole life of each generation and by transmission from generation to generation, all the newly acquired fineness and promptness of the qualities mentioned ought to constitute an inseparable part of the respiratory center. In this sense we may speak of an automatism of the center. But we should understand clearly that the center itself does not generate impulses; the impulses are always transmitted by some reflex from a peripheral point; the center supplies merely the high sensitiveness and the readiness to respond alternately to simultaneous excitation by inspiration and expiration. Now, we may try to answer the above-mentioned objection to the pure reflex theory of respiration in the following way: The impulses for inspiration and expiration are normally transmitted to the respiratory center by reflexes from all parts of the body; the alternation of inspiration and expiration is normally induced and maintained by the sequence of expansion and collapse of the lungs. But, by virtue of repetition and inheritance, the respiratory center possesses an automatic readiness to respond with alternation to simultaneous reflexes for inspiration and expiration

which enables the center to continue a rhythmic breathing, even after exclusion of the main factor for the rhythmic respiration—the lungs.

In conclusion, I wish to add that I am glad to be in full accord with Dr. Cowl in the high appreciation of the invaluable services rendered to the physiology of respiration by Professor Gad, whose investigations served me partly as a basis for my hypothesis; but this latter should be judged on its own merit or demerit, and not by the fact that it differs from the opinion of acknowledged authorities.

179 East 109th Street.

CHILDBED FEVER.*

By THOMAS W. KAY, M. D.,
SCRANTON, PA.

Though childbed fever is a disease nearly as old as the human race, nothing was known of its ætiology till 1846. At that time the mortality of childbirth had increased to fifteen per cent. in the large lying-in hospitals of Vienna, a fact so appalling that Semmelweiss, an assistant physician, was induced to study into its cause and to seek a means for its prevention.

Coming into authority in 1847, he had all physicians and students who attended his wards wash their hands with chlorine water before they were allowed to make a vaginal examination, and by this simple means he reduced the mortality in his special wards in one year from 12·24 per cent. to 1·27 per cent. The results obtained at the present day are far better even than these.

In the summer of 1888 I visited the lying-in hospital at Dresden, and was informed that of the last fifteen hundred women confined not one had died of childbed fever, unless the disease had been contracted before her removal to the hospital, and, moreover, there had not been a single case of ophthalmia neonatorum among the infants.

In recent years the stimulus that has been given to bacteriological research has given us an insight not only into the proper treatment for childbed fever, but also into the agents producing the disease. Without entering into a lengthy discussion of the subject, it is sufficient to state that the *Streptococcus pyogenes* is the cause of all forms of puerperal fever.

Vidal found that, though there were various kinds of microbes in the uterine cavity after parturition, it was only the streptococcus that penetrated its walls, and this occurred only where a lesion of its surface existed. He also found the streptococcus in the pyæmic abscesses of the disease, in the endothelium of the veins in phlegmasia alba dolens, and in the peritoneal cavity in those cases of childbed fever where peritonitis existed. Fränkel did not find the streptococcus in those cases of puerperal peritonitis where a fatal termination had not been reached early in the disease, and he maintains that this was due to the migration of other microbes from the intestines into the peritoneal cavity. These strange microbes either destroy the streptococcus or so modify it that it is very difficult to cultivate and study it outside of the body. The streptococcus has been found by Zweifel in mammary abscesses, and it is now generally admitted that it is also the cause of erysipelas.

If, then, the agent is the same in every case, it seems strange that it is capable of producing such dissimilar results. Let us remember, however, that these germs may possess a different degree of virulence; they may enter the system in small or large numbers, or their point of entrance may affect the result by offering a nidus more or less suitable for their growth and multiplication.

They may also be affected by the presence of other microbes, as Professor Bouchard has shown that two non-pathogenic germs may become pathogenic when they enter the system simultaneously. The *Bacillus prodigiosus* and the microphyte of *charbon symptomatique*, each harmless in itself to the rabbit, will produce a fatal result if introduced into the system at the same time.

Sapræmia, a species of childbed fever, may be produced by the absorption of the products excreted by the microbes without the entrance of the microbes into the system. Mr. Hankin, an Englishman who has been studying the poisons of some of these microbes, finds that the anthrax bacillus owes its ability to live in the body to the excretion of a slowly formed albumose which destroys the germ-resisting power of the body. Strong solutions of this albumose are poisonous, but by using attenuated solutions the body becomes accustomed to it and the bacillus dies. Recently many careful investigations have been made into the germicidal properties of the blood. Chief among these are those of Buchner, Nissen, Foder, Metschnikoff, and Lubarsch, of Europe, and Nutall and Prudden of America.

The results arrived at are, that fresh blood serum at the normal temperature is deadly to the microbes of cholera, anthrax, and typhoid fever, but is less fatal to the streptococcus. Ascitic and hydrocele fluids possess the same power, but this power decreases as the temperature is raised, and it is finally lost when it reaches 121° F.

Formerly great pains were taken in drawing the line between autogenetic and heterogenetic puerperal fever, but since the disease has been more carefully studied we see that it is impossible for it to occur unless the germs are present, and Hegar justly rejects the theory of self-infection entirely. He shows that in Baden the mortality from child-bearing has remained about the same for the last forty years. Though the mortality among those attended by physicians has greatly decreased, it has increased in those attended by midwives. This fact he ascribes to their practice of injecting carelessly a three-per-cent. solution of carbolic acid, and thus introducing germs into the genital tract.

All germs, then, are from without, but they need not necessarily be carried by the physician. They may be already in contact with the genitals and only waiting for a suitable occasion to enter the system, or they may find a suitable nidus in the decomposing lochia, and thus find a way into the genital tract.

Professor Kehrer has made an excellent classification of all cases of childbed fever. He recognizes three groups:

* Read before the Lackawanna County Medical Society, October 14, 1890.

(1) pyæmic, (2) septic, and (3) putrid endometritic. This last corresponds to the sapræmic of some authors. During the last year it has been my fortune to meet with six cases of childbed fever. Four of the patients had been attended by midwives; and of these four, three died, the only one that recovered being one with sapræmia. The two others were attended by physicians—one by myself, a patient with sapræmia, who recovered; the other had septicæmia and died in the hands of a brother practitioner. The brief notes of the three following cases are presented to show imperfect types of the three groups as laid down by Kehrer:

Case I. *Pyæmic Variety.*—Mrs. D. J., a delicate Welsh woman, twenty-six years of age, was delivered, by a midwife, of her third child on April 30, 1890. On May 7th I was called in to treat her for "chills and fever," from which she had suffered since May 3d. These chills had been very severe, occurring once or twice every day, and been followed by profuse sweats. The morning pulse was 136 and the temperature was 103° F., while the whole abdomen was sensitive and tympanitic. Vaginal examination revealed an enlarged and tender uterus, to the front and right of which was situated a firm, immovable mass. Her bowels were somewhat loose and there was slight jaundice of the skin and sclerotics. The treatment adopted was with turpentine stupes and hot poultices to the abdomen, frequent and copious vaginal irrigations of hot antiseptic solutions, and internal remedies. Quinine and antipyrine were given to reduce the temperature, while brandy and caffeine were administered to stimulate the action of the heart. With these, all of the nourishing food was given that the patient could be induced to take.

With an occasional chill, her condition gradually improved, so that on May 17th her temperature had fallen to 99·5° F. I prescribed tonics and did not see her again for several days. On the 19th she had another severe chill, with an elevation of temperature to 104° F., which was reduced to normal with quinine, antipyrine, and caffeine.

She felt so well on the 20th that I was requested to cease my visits, but I was called again on the 25th, and found a case of phlegmasia alba dolens dextra. The nourishment and stimulants were continued, and soothing liniments were applied to the limb while it was enveloped in cotton and elevated on pillows. The temperature, which had risen to 103° F. with the phlegmasia, gradually fell as the swelling subsided, so that by June 2d the patient seemed almost convalescent.

About this time, however, lung symptoms began to develop, and on June 4th well-marked pneumonia existed in the lower lobe of the right lung. A day later, dullness could be distinguished in the posterior portion of the left lung, and from this time on the disease progressed rapidly to a fatal termination. She died, June 8th, at 11.30 P. M. No post-mortem was held.

Though no abscesses could be discovered, the symptoms clearly pointed to the pyæmic variety. Uterine irrigation was not suggested, because systemic infection was well marked, the uterus was extremely tender, and inflammatory deposits existed in its neighborhood.

Case II. *Septicæmic Variety.*—Mrs. J. H., a fleshy Welsh woman, thirty-one years of age, who had had six children, had been in labor for twelve hours, attended by a midwife, when I was sent for on July 23, 1889, and delivered her without instruments, in two hours, of a healthy girl.

Contrary to directions, the clothing and bed-linen were not changed till the following day—some eighteen hours after delivery. By that time the heat had set up decomposition and the smell had become quite offensive. The woman was a midwife herself, and she informed me that she always followed that plan. On the morning of the 25th she was chilly and had a temperature of 101° F., a pulse of 120, and a slightly tympanitic abdomen. The lochia had become very scanty and were somewhat offensive.

Intra-uterine irrigation was attempted, but, as the parts were sore, she positively refused to submit. She was informed as to the possible termination of the case, but expressed no apprehension, as she had always had "chills and fever" after her labors. After opening the bowels freely with a saline cathartic, quinine and antipyrine were given and warm applications were made to the abdomen. Under this treatment the temperature fell for a day to nearly normal, but rose again on the 27th to 104° F. By this time the pulse had become so depressed that alcoholic stimulants and caffeine had to be resorted to, and all the nourishing food given that the woman could assimilate. From this time to August 1st the temperature varied from 102° to 104°, and the pulse from 120 to 140. On July 28th a miliary eruption began to make its appearance, and by August 1st it had covered the whole body, producing an acute dermatitis and lessening the cutaneous excretion. At 5 P. M. on August 1st her temperature was only 103° and she was cheerful and comfortable, with the exception of some hiccough. At 4 o'clock in the morning of the 2d I was sent for and told that the woman had fainted. On my arrival I found her in a comatose condition, with a scarcely perceptible pulse of 160 and an axillary temperature of 109° F. In fifteen minutes she was dead—nine days after delivery.

In this case, if intra-uterine irrigation could have been used at first, there is every reason to believe that the life could have been saved. The coma was probably due to the sudden rise of temperature, which in turn was, most probably, caused by the stoppage of the cutaneous exudation.

Case III. *Putrid Endometritic Variety.*—Mrs. C. P., a fleshy multipara, twenty-seven years of age, had been delivered of four children, and in each of the last three confinements the labor had been difficult and her recovery had been slow, on account of fever, which in her last confinement had kept her in bed for eleven weeks. I was called to her in her fifth confinement, on August 15, 1890, at 9 P. M., and at 10.30 she was delivered of a healthy boy weighing from ten to twelve pounds.

A half hour later the afterbirth was expelled by Credé's method and a bandage applied.

As she usually suffered from after-pains, a mixture of opium and ergot was left which was to be taken as required. The temperature rose only 0·5° F. and there were no complications of any kind except a fissured nipple of the left breast, which healed rapidly under powdered boric acid. As the woman was weak I did not give her permission to rise till August 24th, which she did not avail herself of because of headache. The next morning at 10 o'clock, before she had got up, she was taken with a slight chill and I was sent for. On my arrival the pulse was 140 and the temperature was 104°. She was bathed in perspiration, and prostration was so great that she could not speak above a whisper and was unable to turn in bed. The abdomen was slightly distended and there was some tenderness in the right iliac region. The lochia were scanty, almost colorless, and somewhat offensive in smell. A vaginal examination revealed a tender uterus with the os pretty well closed. The uterine cavity was immediately washed out with a copious injection of hot carbolized water, which brought away several small clots of blood and some shreds of very offensive mucus. The injection was used twice daily, while hot applications were made to the

abdomen, and quinine, antipyrine, caffeine, and French brandy were given internally. The next morning the temperature was subnormal, but she was so weak that the brandy and caffeine were continued, with all the nourishing food that could be taken. A saline cathartic was also given, which produced two copious discharges. On this day a miliary eruption made its appearance over all the body and did not disappear for a week, when slight desquamation took place. The intra-uterine douches were used till September 2d, when, there being no odor from the parts and no elevation of temperature, they were discontinued. The stimulants were continued a few days longer, when tonics were substituted, and the patient was discharged.

This case was clearly one of putrid endometritis, where the poisonous products had been absorbed. Scrupulous care was used during her delivery to prevent infection, and she had the most careful nursing by her mother, who kept everything clean, but, in spite of this, the trouble came on. That such cases are sometimes unavoidable will be seen from the reports of Karl Braun's clinic, at Vienna, where every precaution is used to prevent infection. From March, 1887, to September, 1889, there were 7,600 deliveries in his clinic, and among these there occurred 101 cases of putrid endometritis. It is worthy of note that two thirds of these happened in cases where the placenta and membranes came away intact.

Concerning the treatment of childbed fever, too much stress can not be laid on prophylaxis. The physician should thoroughly cleanse his hands and finger-nails with soap and hot water and a nail-brush; then he should disinfect them in a solution of carbolic acid, bichloride of mercury, or creolin, and finally wash them in alcohol.

All towels and cloths used during labor should be clean, and before each examination the hands should be washed in a disinfectant solution. If it is necessary to use instruments, they should be immersed for a short time in boiling water, and then disinfected before use.

The woman should have a thorough bath during the twenty-four hours preceding labor, and when labor begins the vagina should be thoroughly irrigated with a hot disinfectant solution, because many germs may be found in an apparently healthy vagina. This irrigation should be repeated after the child and the after-birth have been expelled, and if during delivery it has been found necessary to invade the uterine cavity with hands or instruments, this should also be irrigated. Irrigation not only washes away blood-clots and destroys germs, but also arrests hæmorrhage and favors uterine contraction. For this any male catheter will do, but the double catheters are better, among which may be mentioned that of Dr. A. Cordes, of Switzerland.

After irrigation, the genitals should be thoroughly cleansed and all soiled linen removed, and then a broad cloth, folded several times and moistened with a disinfectant solution, should be laid over the genitals so as to receive and disinfect the discharge and prevent the entrance of germs. These cloths should be changed several times every day, and all clothing removed as soon as soiled.

If after delivery we have any reason to think—from headache, general malaise, chilliness, or rise of temperature—that things are going wrong, the uterine cavity should at once be irrigated with copious hot disinfectant solutions. The cause is at first local and situated in the uterine cavity, and, if we expect to meet with success, prompt action must be taken to prevent general infection. After this has taken place, irrigation may assist in removing or destroying the germs that remain in the cavity of the uterus, but it can have no effect on those that have found their way into the system.

In most cases intra-uterine irrigation will be found to be sufficient if resorted to in time, but where the microbes have found their way into the substance of the mucous membrane it is well to curette the endometrium and use antiseptics. Of the 101 patients treated thus by Braun, 96 recovered. Three of those that died had general infection before they were operated on. One of the others died from peritonitis due to previously existing salpingitis, and the other died from exhaustion subsequent to hæmorrhage from injury to some of the uterine vessels. The operation is frequently followed by a slight chill and an elevation in temperature of 1°, but this drops in a few hours, and is rarely followed by complications.

In a late number of the *Deutsche Medizinal-Zeitung* a case is reported where Dr. Stahl curetted for puerperal septic endometritis in a primipara of thirty-five years, in whom the membranes had been retained, but, as the system became infected, as was shown by pelvic venous thrombus, he performed supravaginal hysterectomy and treated the stump by the extraperitoneal method.

I mention this case more as a curiosity in the line of treatment than as an example to follow. If the bacteria have found their way into the peritoneal cavity they will multiply rapidly and set up puerperal peritonitis.

Bouilly was the first to suggest laparotomy for this, and in 1887 he instituted the practice that has been followed with indifferent success by others. A successful case is reported by M. Raymond in *La Semaine médicale* for August 20th. The woman was taken with a chill on the third day after confinement, and her temperature varied from 39·8° to 40·8° C. The abdomen was distended and tender and diarrhœa was present. Prostration was rapid and an ecchymotic spot appeared at the level of the great trochanter, indicating general septicæmia and a metastatic abscess. Laparotomy was performed on August 2d and four quarts of purulent fluid were evacuated with a large mass of jelly-like false membrane. The cavity was irrigated with sublimate solution (1 to 10,000), and drainage was used. On August 13th the woman's condition was normal, though she was still weak.

When Max Runge, some years ago, insisted on alcohol, food, and sponging, he established a course of treatment that is being followed by the best practitioners of to-day. In 1876 Breisky and Conrad laid down rules for the use of alcohol in childbed fever, and since then A. Martin has adopted that plan of treatment in many cases with success. Breisky used alcohol for its apyretic effects, but Martin values it chiefly for its stimulating action on the heart and its power of increasing the patient's resistance against infection. Out of eighteen patients treated thus, only five died, of which three were from infection. The amount of alcohol that can

be borne under such circumstances without the patient's becoming intoxicated is enormous. One patient in six weeks took seventeen bottles of brandy, thirteen bottles of Burgundy, thirty-seven half-bottles of champagne, four bottles and a half of other wines, and six bottles of porter. With the internal treatment he uses all local means that are necessary.

In a recent number of the *Journal of the American Medical Association*, Dr. N. S. Davis advises caution in the use of the anilides in puerperal fever, because they depress the heart and probably lessen the resistance of the blood cells. This warning is timely, for there seems to be a widespread practice of giving antipyrine in childbed fever.

The blood, as we have seen, has a germicidal action of itself, but this action decreases with its elevation of temperature and is finally lost. It is perfectly rational, then, to try and keep the temperature down, and for this, sponging, quinine, and antipyrine can be used. To get the best results it is well to combine all three. Antipyrine should not be given in doses larger than ten grains, which can be repeated as required, and it should always be combined with caffeine to prevent its depressing effects. Caffeine is also useful in counteracting the adynamia accompanying the disease, and Gottschalk has obtained excellent results from the simple administration of strong coffee in large doses.

Huchard uses caffeine in all cases of adynamia, injecting hypodermically from two to three grammes a day. He uses two solutions, the prescriptions being as follows:

Mild Solution.

℞ Sod. benzoat ..... grm. 3;
Caffeinæ ..... grm. 2;
Aq. dest ..... grm. 6. M.

Strong Solution.

℞ Sod. salicylat ..... grm. 3·10;
Caffeinæ ..... grm. 6;
Aq. dest ..... grm. 6. M.

Of these he uses from four to eight Pravaz syringefuls a day. Where much tenderness and distention of the abdomen exist, hot or cold applications may be used according to the comfort of the patient, and occasional saline cathartics may be used to drain the peritoneal cavity and prevent intestinal adhesions. If much nausea or vomiting is present, small doses of cocaine will be found to arrest it. Opiates should be given only when the amount of pain demands them, and arterial sedatives should be avoided, as they do more harm than good. In all cases a liberal supply of the most nourishing food should be insisted on, and the most careful nursing obtained that is possible.

THE IMPORTANCE OF PROMPT TREATMENT IN ALVEOLAR ABSCESS, *WITH CASES.*

By J. D. MacPHERSON, M. D.,
ASSISTANT SURGEON TO THE PRESBYTERIAN HOSPITAL DISPENSARY.

Although usually considered as a somewhat trivial affair, an alveolar abscess, if improperly treated, may prove serious enough. So many of these cases have come to my notice lately, in both dispensary and private practice, that I have become impressed with their gravity and need of

prompt attention. These abscesses are of two forms, viz., superficial and deep.

The superficial, commonly called gum-boils, are marked by a small puffy swelling of the mucous membrane at the side of a tooth, and occur on either the buccal or the labial surface of the alveolus. They may be due to diseased teeth or to "catching cold," or may be idiopathic, and are more apt to occur when the root of the tooth causing the trouble does not pass below the fold of mucous membrane uniting the gum and cheek. They are usually small in size, but often very tender and painful to the touch. They are of short duration and, their walls being thin, either rupture spontaneously or by pressure of the finger, when recovery rapidly takes place.

The deep abscesses are much more serious; these more directly result from diseased or dead teeth (at times from an impacted wisdom tooth), the exciting cause being usually exposure to wet or cold. In the case of diseased teeth, the irritating products of decomposition pass through the tooth canal and set up an acute inflammation of the circumdental membrane. This membrane being very vascular, inflammation proceeds rapidly from the apex to the neck of the tooth. The swelling of the membrane pushes the tooth up slightly from its cavity, loosening it somewhat. The inflammation extends to surrounding tissues, which become more or less swollen and painful. The inflammatory process may stop here and recovery take place without the formation of pus, but frequently (especially if the tooth is not drawn) the process continues and suppuration rapidly follows.

The pus being confined on all sides by bony walls, it follows the natural law and seeks an outlet where there is the least resistance by the absorption of the thin alveolar process. In this form the pus is below the fold of the mucous membrane connecting the gum and cheek, so they do not open (spontaneously) into the mouth as a rule, but the pus burrows in all directions, forming an abscess of greater or less extent, depending on the severity of the inflammatory process and the resistance of the surrounding tissues. The abscess may burst in several directions, sometimes at a considerable distance from the starting point.

In rare cases, when a tooth of the upper jaw is affected, the abscess may rupture into the nasal cavity, in the neighborhood of the hard palate, and, in case of the bicuspids, into the antrum of Highmore. In one case of the latter, which I assisted in operating on, a sinus had opened on the face and had been discharging for eight years. It healed up promptly after the tooth had been drawn and necrosed bone removed. Abscesses connected with the lower teeth may point under the chin, in the neck, and even as low as the arm-pit. Such cases are always serious and may be fatal.

At Bramann's clinic in Berlin I have several times seen him point out a diseased lower molar as the cause of an abscess pointing in the neighborhood of the clavicle.

Not infrequently the pus burrows through the intervening tissues and bursts on the face, leaving a tortuous sinus filled with unhealthy granulations, at the bottom of which necrosed bone can usually be felt. These fistulæ are generally very slow to heal, often taking months and even years, and frequently leave unsightly scars. The symptoms vary with the severity of the case. In the milder forms there may be only local tenderness, increased by mastication, and slight swelling. In the more severe, the affected tooth is loosened and tender, and the pain is increased by bringing the teeth sharply together or tapping on them with some hard object.

The formation of pus may be accompanied by a chill, followed by a rise of temperature (101° to 103° F.), rapid pulse, and sometimes considerable depression. The pain varies in severity; in some cases it is very sharp and lancinating, but usually it is only a dull, steady ache.

In mild cases the swelling is but slight, while in the more severe it may involve the subcutaneous tissues of the cheek, lips, eyelids, and neck of the affected side, making the patient a most unsightly object. The tongue and mucous membranes of the mouth may also be involved, when mastication will be impossible and deglutition difficult and painful.

In the early stages, before the formation of pus, an attack may sometimes be aborted by a brisk cathartic, quinine, gr. x, and the local application of an evaporating lotion. When it is too late for this, the diseased tooth should be drawn at once, after which, unless the process has gone too far, the inflammation subsides, and the patient is well in two or three days.

About a year ago, while making a tour through the Black Forest in southern Germany on foot, after exposure to the wet one of our party was taken with pain in the right side of his jaw, evidently due to a diseased lower molar. His face soon began to swell and became very painful. Our stock of drugs (a bottle of brandy and some peppermint) failed to give any relief. We were miles from the nearest town, so the poor fellow had a pretty hard time of it until we arrived in Freiburg. Here we hunted up a dentist, who, for a mark and a half (thirty-seven cents), injected cocaine, drew the offending grinder, and gave him some potassium permanganate to gargle with. The next day all pain and swelling had disappeared and he was practically well. I could cite some twenty such cases in which early extraction was performed, when the trouble at once subsided.

All dentists are not so accommodating as the one just mentioned, and many of them will refuse to draw the tooth while inflammation is going on, the reason for which I have never been able to find out.

Patients frequently come to the dispensary with all the symptoms of dental abscess, and, when they are ordered to go to a dentist and have the tooth drawn, the reply is: "I did go to one yesterday, but he said he wouldn't pull it till the swellin' went down."

Many of these patients recover, it is true, but those that do not, and have subsequent necrosis of the jaw and a troublesome sinus, make conservative measures appear decidedly risky, to say the least. Generally this is the patient's own fault, and, unless the pain is very severe, he would rather bear it than have the tooth extracted.

The following case will illustrate:

CASE I.—Mrs. K., twenty-eight, German, consulted me in May, 1890, about a painful swelling on the right side of her face, evidently due to a carious lower molar. I advised her to have the tooth drawn at once. Being of a very nervous temperament and dreading the pain, she put it off for a week, and then had it drawn under gas. About two weeks later she came to me again; the abscess had ruptured externally, leaving an unhealthy fistula, filled with fungous granulations and discharging offensive pus. The patient was pale and anæmic and considerably run down. No necrosed bone could be felt at the bottom of the sinus, so it was cleansed and dressed antiseptically, and the patient put on the use of syr. ferri iod. and cod-liver oil.

Treatment was continued for about a month, when, there being no improvement, I concluded to operate. On July 16th, the patient etherized, an incision was made parallel to the lower border of the jaw, going down to the bone. All broken-down tissue that could be found was removed with a sharp scoop. Wound thoroughly cleansed and dressed antiseptically. Some improvement followed, but on August 20th it was found necessary to operate again. This time a considerable amount of necrosed bone was removed with a chisel, and all diseased tissue carefully cut away. The wound was dressed antiseptically. Since that time the patient has been taking tonics and the wound carefully treated; but repair has gone on very slowly, and it was not until October 22d that the discharge had ceased and the wound was entirely healed.

The debilitated condition of the patient in this case before the trouble began, probably had much to do with her slow recovery. Still, I have no doubt that, if the tooth had been drawn at first as directed, all this trouble and suffering would have been avoided.

In healthy subjects, even after the abscess has opened externally and considerable necrosis taken place, if treated properly, the cavity heals up kindly. The following two cases, occurring in private practice, are good examples:

CASE II.—M. S., a Bavarian, always strong and healthy, came to me on June 4th. About two weeks before, the left side of her face became swollen and painful; she could not eat or sleep. She began to poultice it, and in three days an abscess pointed and ruptured externally. She then went to a dentist, who drew the diseased left lower bicuspid which caused the trouble. The abscess had been discharging ever since, and she then had an ugly sore over the body of the lower jaw, midway between the ramus and the symphysis. This was filled with unhealthy granulations, and at the bottom of the sinus, found at one point, dead bone could be felt. On June 5th the patient was etherized, the parts were cleansed, all unhealthy granulations were removed with a sharp scoop, and the sinus was scraped. An incision was made parallel with the lower border of the jaw, passing through the sinus and going down to the bone. A grooved director was passed through the alveolar cavity into the mouth and the opening enlarged. All necrosed bone was removed with a small gouge, making a straight tract from the tooth cavity to the external wound. The wound was cleansed antiseptically, a strip of iodoform gauze passed through into the mouth, and the wound packed with the same. The wound granulated well, and on June 26th was entirely healed, only a linear cicatrix remaining.

CASE III.—M. R., Ireland; never had been sick before; consulted me on September 15th.

Two weeks before, a diseased right lower molar became tender and painful and soon after the face began to swell. She poulticed it for several days without relief, then went to a dentist, who drew the tooth and stopped the poulticing. The face was still swollen and painful when I saw her. As the abscess was about to burst externally, it was incised and dressed antiseptically. Treatment was continued for a week, when, there being no improvement and necrosed bone being felt in the wound, an operation was advised. On September 25th the patient was etherized and the parts were cleansed. With a sharp scoop I removed all fungous granulations from the sinus, and the opening was enlarged by an incision parallel with the body of the jaw. A director was passed through a tortuous fistula into the alveolar cavity and the opening enlarged. All diseased bone was removed with a small gouge and the wound cleansed antiseptically. A strip of iodoform gauze was passed through into the mouth and the wound packed with the same. The patient was put on soft diet and the mouth washed frequently with weak carbolic solution. The opening into the mouth closed in a few days, and the wound did nicely, with but slight discharge of pus.

On October 19th it was entirely healed, leaving a small but adherent cicatrix.

In conclusion, I would say (and the facts seem to warrant it) that the proper treatment in these cases, when the attack can not be aborted in its early stages, is the immediate extraction of the affected tooth. Even though the tooth may be a valuable one and in a conspicuous place, I think it is far better to take it out than to run the risk of an alveolar abscess, which, even if checked for a time, may occur again and again, is liable to cause the patient weeks of suffering, and may disfigure him for life. Modern dentistry has advanced so that now an artificial tooth looks as well and is almost as serviceable as a natural one. Poultices, as a rule, do more harm than good, as they tend to make the abscess open externally, and, I believe, help induce periostitis, especially before the tooth has been drawn. A steamed fig or a small roasted onion held in the mouth and frequently changed is much better.

In two of the cases cited in which poultices were used the abscess opened externally after the tooth had been extracted.

According to most of the text-books, although a sinus following one of these abscesses may have existed for years, it will close up directly after the tooth has been drawn. Several of the foregoing cases will show that this is not always so.

If drawing the tooth does not relieve, a free incision should be made over the swelling within the mouth as soon as fluctuation is felt, when, even if quite extensive periostitis has taken place, if the wound is kept open, it will usually heal up kindly from the bottom in a healthy subject.

When an abscess opens externally and shows no tendency to heal within a reasonable time, I believe it should be opened freely, and the alveolar cavity cleaned out and allowed to heal up from the bottom.

The Nuclei of Biliary Calculi.—"According to Dr. Naunyn, of Strasburg, biliary calculi, though they appear to have gathered round a cholesterin nucleus, do not arise primarily from masses of this substance, but from some soft matter shed by the walls of the biliary passages, which becomes impregnated with cholesterin, not so much from the bile, perhaps, as from the catarrhal secretion of the mucous membrane of the biliary passages."—*Lancet.*

NEW YORK, SATURDAY, NOVEMBER 22, 1890.

KOCH'S ALLEGED CURE FOR TUBERCULOSIS.

In an address before the Tenth International Medical Congress, as our readers are aware, Professor Robert Koch, of Berlin, intimated that he was engaged in a course of experimental research that seemed to him likely to lead to the successful treatment of tuberculosis. Coming from such a man as Koch, that guarded statement was most encouraging, for everybody felt that he was the last man in the world to take a visionary view of such a matter; he had always worked his problems quietly to their indubitable solution, and it was taken for granted that he would do so in this instance. Nobody in the medical profession needed to be told that such a course would require many months of investigation, and there was a firm conviction that Koch was not the man to jump to conclusions. Hence the repeated newspaper statements that he was soon to proclaim his results and conclusions were received with incredulity. But it seems that he has swerved from the line of conformity to precedents established by himself, and has published a statement of his unfinished work, in the form of an article in the *Deutsche medicinische Wochenschrift*. This has been translated into English and published in the *British Medical Journal* and in the *Medical News;* moreover, the gist of it has been telegraphed to the newspapers, and they have spread it before the public, generally with the accompaniment of some such immoderate statement as that Koch has made a discovery of greater importance to mankind even than that of vaccination..

The communication deals almost entirely with the observed effects of the remedy and with the theory of its action; nothing is said of the manner of its preparation, and we are kept entirely in the dark concerning the experimental work that led up to its production. In fact, Koch expressly declines to say more of its nature than that it is a clear, brownish liquid which keeps well when undiluted, but not so well when diluted to the degree called for in its therapeutic employment, although the addition of a little phenol to the diluted liquid overcomes its susceptibility to change to a certain extent. Practically, therefore, it is a secret remedy, and, if it had originated in this country, that fact would preclude its being taken into serious consideration by physicians; but they take a different view of such things in Germany, and it must not be set down to Koch's discredit that he has preferred to keep the nature of his remedy secret for the present, especially as he founds his decision on a natural dread lest inexperienced persons may attempt to make the liquid for themselves, with the result of producing an article capable of doing much harm. In further extenuation of his policy as to this point is his offer to supply physicians with the liquid to as great an extent as the present difficulties attending its production admit of; but it is already reported that applications for it are far in excess of what can be furnished, so that this clear, brownish liquid is the veritable *γάλα ὀρνίθων* of the day.

Koch states that the remedy has no effect when taken by the stomach, but must be used subcutaneously. He injects it beneath the skin of the middle portion of the back, even in cases of external tubercular diseases, such as lupus, that might readily be subjected to its topical action, if it has any. An injection of 0·25 of a cubic centimetre causes in a person who is not tuberculous a decided rise of temperature, with headache, pains in the limbs, etc. Like effects result from much smaller doses in those who have lupus, tubercular disease of the glands, etc.; and in persons with pulmonary tuberculosis so small a dose as 0·01 of a cubic centimetre suffices for their production, and this is the proper initial dose, although succeeding doses may safely be made larger and larger with a rapidity that Koch thinks not wholly to be accounted for on the ground of tolerance in the ordinary sense of the word. In cases of lupus, the fever is followed by remarkable phenomena in the diseased part; it becomes red and swollen, in some instances with vesiculation, and a crust is formed which, when it falls off, leaves a smooth, clean surface—in some cases a single injection sufficing to bring about this happy result. Koch makes the positive statements that lupus is thus cured by his remedy alone; that in glandular and osseous tubercular affections subsequent surgical intervention may be required to remove the *débris*, thus completing the cure; and that cases of incipient pulmonary consumption have shown under the employment of his remedy such symptoms of improvement as to lead him to think them cured, although he is not positive that relapses may not occur, but thinks that, if they do, they will be quite as amenable to the treatment as the original trouble was.

Koch's theory of the curative action of the remedy is, not that it kills the bacilli, but that it sets up in the diseased living tissue a process that ends in its necrosis; and he implies that the bacilli are cast off with the dead tissue, and that incompleteness of this part of the process may lead to re-infection, as also may failure of the dead tissue to become wholly separated from the organism.

To support all this, he gives absolutely no statistical evidence and not a single clinical history. We have only his statements, which in some respects are rather vague. We may add that so astounding are these statements—so utterly at variance with any known biological laws—that nothing but Koch's great name and the prevalent confidence in his accuracy, produced by his past successes, would lead one to consider his article at all seriously. He states positively that patients in the first stage of phthisis were freed from every symptom of disease, and might be pronounced cured; that patients with cavities not yet too highly developed improved considerably, and were almost cured; but that in very advanced cases there was no improvement. He says that by this he is led to suppose that phthisis, in the beginning, can be cured with certainty by

his remedy, but he admits that, thus far, no conclusive experience can be brought forward to prove that the cure is lasting.
